Despite the IEC standards, the traditional method when discussing floppy drives or disks is to refer to the capacity of a floppy by the number of kilobinary bytes (1,024 bytes equals 1KiB) but to use the otherwise improper abbreviation KB instead. This has also been improperly extended to the abbreviation MB. Therefore, a floppy disk with an actual capacity of 1,440KiB is instead denoted as a 1.44MB disk, even though it would really be 1.406MiB (megabinary bytes) or 1.475MB (million bytes) if we went by the

correct definitions for MiB (mebibyte) and MB (megabyte).

For the remainder of this chapter, I will refer to the capacity of the various floppy disks according to the previously used conventions rather than the more technically accurate IEC-designated binary and decimal prefixes.

Note

As with hard disk drives, using the same prefixes for both decimal and binary multiples has resulted in a great deal of confusion. The IEC prefixes for binary multiples was designed to eliminate this confusion. For more information on prefixes for binary multiples, see <http://physics.nist.gov/cuu/Units/binary.html>. Also, refer to the section "[Capacity Measurements](#)" in [Chapter 9](#), "Hard Disk Storage."

Like blank sheets of paper, new, unformatted disks contain no information. Formatting a disk is similar to adding lines to the paper so you can write straight across. Formatting the disk writes the information the operating system needs to maintain a directory and file table of contents. A full format rewrites the file system structures, removing any existing data in the process. This is the equivalent of both a high-level and low-level format on a hard disk. However, unlike a hard disk, a floppy disk does not need to be partitioned.

Note

The Quick Format option available in most versions of Windows, including Windows XP, erases the contents of the disk and verifies the file system rather than rewriting the file system. If you run FORMAT.EXE from the command line, the /Q option also performs a quick format. Unfortunately, Quick Format is not very good at determining whether you have problems with your floppy disk's file system. If you need to ensure that the floppy disk is properly formatted (such as in the case of a used disk you want to use for another task), you should not use the Quick Format option. Windows NT, 2000, and XP perform a full (low-level) format that rewrites the file system and clears the disk if Quick Format is not selected. Windows 9x/Me offers Quick (erase), which is the same as selecting Quick Format, Full, Copy System Files Only in Windows XP. Select Full to rewrite the file system and clear the disk of existing data.

When you format a floppy disk, the operating system reserves the track nearest to the outside edge of a disk (track 0) almost entirely for its purposes. Track 0, Side 0, Sector 1 contains the Volume Boot Record (VBR), or Boot Sector, that the system needs to begin operation. The next few sectors contain the file allocation tables (FATs), which keep records of which clusters or allocation units on the disk contain file information and which are empty. Finally, the next few sectors contain the root directory, in which the operating system stores information about the names and starting locations of the files on the disk.

Note that floppy disks have been sold in preformatted form for a few years now. This saves time because the formatting can take a minute or more per disk. Even if disks come preformatted, they can always be reformatted later. This is useful if you accidentally purchased MAC-formatted disks for your PC; a PC can't use a MAC-formatted disk unless you reformat it.

Cylinders

When discussing the location of data on a floppy disk, the cylinder number is normally used in place of the track number because all floppy drives today are double-sided. A cylinder on a floppy disk includes two tracks: the one on the bottom of the disk above Head 0 and the one on the top of the disk below Head 1. Because a disk can't have more than two sides and the drive has two heads, there are always two tracks per cylinder for floppy disks. Hard disk drives, on the other hand, can have multiple disk platters each with two heads resulting in many tracks per single cylinder. The simple rule is that there are as many tracks per cylinder as there are heads on the drive.

Cylinders were discussed in more detail in [Chapter 9](#).

Clusters or Allocation Units

A *cluster* also is called an *allocation unit*. The term is appropriate because a single cluster is the smallest unit of the disk that the operating system can allocate when it writes a file. A cluster or an allocation unit consists of one or more sectors usually a power of two (1, 2, 4, 8, and so on). Having more than one sector per cluster reduces the FAT size and enables the OS to run more quickly because it has fewer individual clusters to manage. The tradeoff is in some wasted disk space. Because the OS can manage space only in the cluster size unit, every file consumes space on the disk in increments of one cluster. However, 3 1/2" 1.44MB floppy drives store so little information that the default cluster (allocation unit) size is one sector (512 bytes).

Disk Change

The standard PC floppy controller and drive use a special signal on pin 34 called *Disk Change* to determine whether the disk has been changed or more accurately, to determine whether the same disk loaded during the previous disk access is still in the drive. Disk Change is a pulsed signal that changes a status register in the controller to let the system know that a disk has been either inserted or ejected. This register is set to indicate that a disk has been inserted or removed (changed) by default.

The register is cleared when the controller sends a step pulse to the drive and the drive responds, acknowledging that the heads have moved. At this point, the system knows that a specific disk is in the drive. If the Disk Change signal is not received before the next access, the system can assume that the same disk is still in the drive. Any information read into memory during the previous access can therefore be reused without rereading the disk.

Because of this process, systems can buffer or cache the contents of the FAT or directory structure of a disk in the system's memory. By eliminating unnecessary rereads of these areas of the disk, the apparent speed of the drive is increased. If you move the door lever or eject button on a drive that supports the Disk Change signal, the DC pulse is sent to the controller, thus resetting the register and indicating that the disk has been changed. This procedure causes the system to purge buffered or cached data that had been read from the disk because the system can't be sure that the same disk is still in the drive.

One interesting problem can occur when certain drives are installed in a 16-bit or greater system. As mentioned, some drives use pin 34 for a "Ready" (RDY) signal. The RDY signal is sent whenever a disk is installed and rotating in the drive. If you install a drive that has pin 34 set to send RDY, the system thinks it is continuously receiving a Disk Change signal, which causes problems. Usually, the drive fails with a Drive Not Ready error and is inoperable. The only reason the RDY signal exists on some drives is that it happens to be a part of the standard Shugart SA400 disk interface; however, it has never been used in PC systems.

The biggest problem occurs if the drive should be sending the DC signal on pin 34 but isn't. If a system is told (through CMOS setup) that the drive is any type other than a 360KB (which can't ever send the DC signal), the system expects the drive to send DC whenever a disk has been ejected. If the drive is not configured properly to send the signal, the system never recognizes that a disk has been changed. Therefore, even if you do change the disk, the system still acts as though the first disk is in the drive and holds the first disk's directory and FAT information in RAM. This can be dangerous because the FAT and directory information from the first disk can be partially written to any subsequent disks written to in the drive.

Caution

If you have ever seen a system with a floppy disk drive that shows "phantom directories" of the previously installed disk, even after you have changed or removed it, you have experienced this problem firsthand. The negative side effect is that all disks after the first one you place in this system are in extreme danger. You likely will overwrite the directories and FATs of many disks with information from the first disk.

If it's even possible at all, data recovery from such a catastrophe can require quite a bit of work with utility programs, such as Norton Utilities (part of the Norton SystemWorks suite). These problems with Disk Change most often are traced to an incorrectly configured drive. A damaged floppy cable can also cause Disk Change to fail.

Windows Explorer doesn't always display the new contents of a drive. Press the F5 key to refresh the display after you change floppy disks to force the computer to read the new disk.

If the drive you are installing is a 5 1/4" 1.2MB or 3 1/2" 720KB, 1.44MB, or 2.88MB drive, be sure to set pin 34 to send the Disk Change (DC) signal. Most drives come permanently preset this way, but some older drives have used a jumper (usually labeled DC) to set this option.

Analyzing 3 1/2" Floppy Disk Media Construction

3 1/2" disks differ from the older 5 1/4" disks in both construction and physical properties. The flexible (or floppy) disk is contained within a plastic jacket. The 3 1/2" disks are covered by a more rigid jacket than are the 5 1/4" disks. The disks within the jackets, however, are virtually identical except, of course, for size.

The 3 1/2" disks use a much more rigid plastic case than 5 1/4" disks, which helps stabilize the magnetic medium inside. Therefore, the disks can store data at track and data densities greater than the 5 1/4" disks (see [Figure 10.8](#)). A metal shutter protects the media-access hole. The drive manipulates the shutter, leaving it closed whenever the disk is not in a drive. The medium is then completely insulated from the environment and from your fingers. The shutter also obviates the need for a disk jacket.

Figure 10.8. Construction of a 3 1/2" floppy disk.

Because the shutter is not necessary for the disk to work, you can remove it from the plastic case if it becomes bent or damaged. Pry it off the disk case; it will pop off with a snap. You also should remove the spring that pushes it closed. Additionally, after removing the damaged shutter, you should copy the data from the damaged disk to a new one.

Rather than an index hole in the disk, the 3 1/2" disks use a metal center hub with an alignment hole. The drive "grasps" the metal hub, and the hole in the hub enables the drive to position the disk properly.

On the lower-left part of the disk is a hole with a plastic sliderthe write-protect/enable hole. When the slider is positioned so the hole is visible, the disk is *write-protected*, meaning the drive is prevented from recording on the disk. When the slider is positioned to cover the hole, writing is enabled, and you can save data to the disk. For more permanent write-protection, some commercial software programs are supplied on disks with the slider removed so you can't easily enable recording on the disk. This is exactly opposite of a 5 1/4" floppy, in which covered means write-protected, not write-enabled.

On the other (right) side of the disk from the write-protect hole is usually another hole called the media-density-selector hole. If this hole is present, the disk is constructed of a special medium and is therefore an HD or ED disk. If the media-sensor hole is exactly opposite the write-protect hole, it indicates a 1.44MB HD disk. If the media-sensor hole is located more toward the top of the disk (the metal shutter is at the top of the disk), it indicates a 2.88MB ED disk. No hole on the right side means that the disk is a low-density disk. Most 3 1/2" drives have a media sensor that controls recording capability based on the absence or presence of these holes.

The actual magnetic medium in both the 3 1/2" and 5 1/4" disks is constructed of the same basic materials. They use a plastic base (usually Mylar) coated with a magnetic compound. High-density disks use a cobalt-

ferric compound; extended-density disks use a barium-ferric media compound. The rigid jacket material on the 3 1/2" disks has occasionally caused people to believe incorrectly that these disks are some sort of "hard disk" and not really a floppy disk. The disk cookie inside the 3 1/2" case is just as floppy as the 5 1/4" variety.

Floppy Disk Media Types and Specifications

This section examines the types of disks that have been available to PC owners over the years. Especially interesting are the technical specifications that can separate one type of disk from another, as [Table 10.4](#) shows. The following sections define all the specifications used to describe a typical disk.

Table 10.4. Floppy Disk Media Specifications

Media Parameters	5 1/4"			3 1/2"		
	Double-Density (DD)	Quad-Density (QD)	High-Density (HD)	Double-Density (DD)	High-Density (HD)	Extra High-Density (ED)
Tracks per inch (TPI)	48	96	96	135	135	135
Bits per inch (BPI)	5,876	5,876	9,646	8,717	17,434	34,868
Media formulation	Ferrite	Ferrite	Cobalt	Cobalt	Cobalt	Barium
Coercivity (oersteds)	300	300	600	600	720	750
Thickness (micro-in.)	100	100	50	70	40	100
Recording polarity	Horiz.	Horiz.	Horiz.	Horiz.	Horiz.	Vert.

5 1/4" quad-density (QD) disks were never used as an official standard for PCs. They were widely used, however, by the Tandy 2000 (a semicompatible MS-DOS computer that used the rare Intel 80186 processor and was introduced shortly before the IBM AT in 1984), the Tandy Color Computer and other computers running the OS-9 operating system, and some CP/M computers. A QD disk can be reformatted as a double-density disk by a PC that has a 360KB floppy drive.

Density

Density, in simplest terms, is a measure of the amount of information that can be reliably packed into a specific area of a recording surface. The keyword here is *reliably*.

Disks have two types of densities: longitudinal density and linear density. *Longitudinal density* is indicated by how many tracks can be recorded on the disk and is often expressed as a number of tracks per inch (TPI). *Linear density* is the capability of an individual track to store data and is often indicated as a number

of bits per inch (BPI). Unfortunately, these types of densities are often confused when discussing different disks and drives.

Media Coercivity and Thickness

The *coercivity* specification of a disk refers to the magnetic-field strength required to make a proper recording. Coercivity, measured in oersteds, is a value indicating magnetic strength. A disk with a higher coercivity rating requires a stronger magnetic field to make a recording on that disk. With lower ratings, the disk can be recorded with a weaker magnetic field. In other words, the lower the coercivity rating, the more sensitive the disk.

HD media demands higher coercivity ratings so the adjacent magnetic domains don't interfere with each other. For this reason, HD media is actually less sensitive and requires a stronger recording signal strength.

Another factor is the thickness of the disk. The thinner the disk, the less influence a region of the disk has on another adjacent region. The thinner disks, therefore, can accept many more bits per inch without eventually degrading the recording.

Caring for and Handling Floppy Disks and Drives

Most computer users know the basics of disk care. Disks can be damaged or destroyed easily by the following:

- Touching the recording surface with your fingers or anything else
- Writing on a disk label (which has been affixed to a disk) with a ball-point pen or pencil
- Bending the disk
- Spilling coffee or other substances on the disk
- Overheating a disk (leaving it in the hot sun or near a radiator, for example)
- Exposing a disk to stray magnetic fields

Despite all these cautions, disks are rather hardy storage devices; I can't say that I have ever destroyed one by just writing on it with a pen and I do so all the time. I am careful, however, not to press too hard, so I don't put a crease in the disk. Also, touching a disk's magnetic surface does not necessarily ruin a disk, but rather makes the disk and your drive head dirty with oil and dust. The real danger to your disks comes from magnetic fields that, because they are unseen, can sometimes be found in places you never imagined.

For example, all color monitors (and color TV sets) that use cathode-ray tube (CRT) technology have a degaussing coil around the face of the tube that demagnetizes the shadow mask when you turn on the monitor. If you keep your disks anywhere near (within 1[pr] of) the front of a color monitor, you expose them to a strong magnetic field every time you turn on the monitor. Keeping disks in this area is not a good idea because the field is designed to demagnetize objects, and it indeed works well for demagnetizing disks. The effect is cumulative and irreversible. Note that LCD or plasma displays don't have degaussing coils and therefore do not affect magnetic media.

Another source of powerful magnetic fields is an electric motor found in vacuum cleaners, heaters, air conditioners, fans, electric pencil sharpeners, and so on. Do not place these devices near areas where you store disks. Audio speakers also contain magnets, but most of the speakers sold for use with PCs are shielded to minimize disk corruption.

Store 3 1/2" disks between 40° and 127° Fahrenheit (4°53° Celsius), and store 5 1/4" disks between 40°

and 140° Fahrenheit (4°60° Celsius). In both cases, humidity should not exceed 90%.

Airport X-Ray Machines and Metal Detectors

One of my favorite myths to dispel is that the airport X-ray machine somehow damages disks. I have a great deal of experience in this area from having traveled around the country for the past 20 years or so with disks and portable computers in hand. I fly about 150,000 miles per year, and my portable computer equipment and disks have been through X-ray machines hundreds of times.

X-rays are essentially just a form of light, and disks and computers are not affected by X-rays at anywhere near the levels found in these machines.

What could potentially damage your magnetic media is the metal detector. Metal detectors work by monitoring disruptions in a weak magnetic field. A metal object inserted in the field area causes the field's shape to change, which the detector observes. This principle, which is the reason the detectors are sensitive to metal objects, can be dangerous to your disks; the X-ray machine, however, is the safest area through which to pass either your disk or your computer.

The X-ray machine is not dangerous to magnetic media because it merely exposes the media to electromagnetic radiation at a particular (very high) frequency. Blue light is an example of electromagnetic radiation of a different frequency. The only difference between X-rays and blue light is in the frequency, or wavelength, of the emission.

Some people worry about the effect of X-ray radiation on their system's EPROM (erasable programmable read-only memory) chips. This concern might actually be more valid than worrying about disk damage because EPROMs are erased by certain forms of electromagnetic radiation. In reality, however, you do not need to worry about this effect either. EPROMs are erased by direct exposure to very intense ultraviolet light. Specifically, to be erased, an EPROM must be exposed to a 12,000uw/cm² UV light source with a wavelength of 2,537 angstroms for 1520 minutes, and at a distance of 1". Increasing the power of the light source or decreasing the distance from the source can shorten the erasure time to a few minutes.

The airport X-ray machine is different by a factor of 10,000 in wavelength. The field strength, duration, and distance from the emitter source are nowhere near what is necessary for EPROM erasure. Many circuit-board manufacturers even use X-ray inspection on circuit boards (with components including EPROMs installed) to test and check quality control during manufacture.

Now, you might not want to take my word for it, but scientific research has been published that corroborates what I have stated. A study was published by two scientistsone of whom actually designs X-ray tubes for a major manufacturer. Their study was titled "Airport X-rays and Floppy Disks: No Cause for Concern" and was published in 1993 in the journal *Computer Methods and Programs in Biomedicine*. According to the abstract,

A controlled study was done to test the possible effects of X-rays on the integrity of data stored on common sizes of floppy disks. Disks were exposed to doses of X-rays up to seven times that to be expected during airport examination of baggage. The readability of nearly 14 megabytes of data was unaltered by X-irradiation, indicating that floppy disks need not be given special handling during X-ray inspection of baggage.

In fact, the disks were retested after two years of storage, and there was still no measurable degradation following the exposure.

Floppy Drive Installation Procedures

In most cases, installing a floppy disk drive is a matter of physically attaching the drive to the computer chassis or case and then plugging the power and signal cables into the drive. Some types of brackets and screws are usually required to attach the drive to the chassis, and these are normally included with the chassis or case itself. Several companies listed in the Vendor List on the DVD specialize in cases, cables, brackets, screw hardware, and other items useful in assembling systems or installing drives.

Note

Because floppy disk drives are generally installed into the same half-height bays as hard disk drives, the physical mounting of the drive in the computer case is the same for both units. See the section "Hard Disk Installation Procedures" in [Chapter 12](#), "Physical Drive Installation and Configuration," for more information on the process.

Troubleshooting Floppy Drives

For information on troubleshooting floppy drives, see "[Troubleshooting Floppy Drives](#)" in the Technical Reference section on the DVD packaged with this book.

High-Capacity Magnetic Storage Devices

High-capacity removable media drives are an ever-shrinking category. With competition at the low end (1GB and under capacities) from USB flash memory keychain drives and at higher capacities from external mini-hard disks (4GB and up), rewritable DVD (8.5GB), and larger USB and FireWire hard disks (20GB and up), there are only two current product families, both from Iomega:

- *Zip*. Flexible media, with capacities of 100MB, 250MB, and 750MB
- *REV*. Rigid media, with capacity of 35GB (native) up to 90GB (2.6: 1 compression)

Other removable-media drives manufactured in the last few years have been discontinued. These include

- Iomega PocketZip (originally Klik!)
- Imation LS-120 SuperDisk
- Imation LS-240 SuperDisk
- SyQuest (SparQ, SyJet, and all other models)
- Iomega Jaz
- Castlewood Orb
- Iomega Peerless

If you use any of the drives in the discontinued list, you should consider moving your data to current magnetic, tape, or optical storage technologies. A discontinued removable-storage drive is essentially an orphan. There are three reasons for this:

- Repairs can be difficult to come by, especially in the case of a product such as the Castlewood Orb, whose manufacturer (Castlewood Systems) went bankrupt in 2004 and no longer offers online or other forms of support.
- Unlike other storage technologies such as floppy, CD, DVD, and tape, media for removable-media drives is usually proprietary and can only be obtained from the original manufacturer in most cases.
- Most removable-media drives require special drivers to function. As new versions of Windows and other operating systems are delivered, a removable-media drive that works, mechanically speaking, might not be compatible.

[Table 10.5](#) provides an overview of current and recent high-capacity (100MB and larger) magnetic removable-media drives. The following sections provide additional detail about current models.

Table 10.5. Current and Recent High-Capacity Magnetic Removable-Media Drives

Removable Media Drive	Manufacturer	Media Type (Technology)	Capacity	Status	Notes
PocketZip	Iomega	Flexible (magnetic)	40MB	Discontinued	1

Zip 100	Iomega	Flexible (magnetic)	100MB	Current	2
LS-120 SuperDisk	Imation, others	Flexible (floptical)	120MB	Discontinued	3, 4
LS-240 SuperDisk	Imation, others	Flexible (floptical)	240MB	Discontinued	3, 4, 5
Zip 250	Iomega	Flexible (magnetic)	250MB	Current	2, 6
Zip 750	Iomega	Flexible (magnetic)	750MB	Current	2, 7
SparQ	SparQ	Rigid (magnetic)	1GB	Discontinued	8
Jaz	Iomega	Rigid (magnetic)	1GB	Discontinued	9
Jaz	Iomega	Rigid (magnetic)	2GB	Discontinued	9, 10
Orb 2.2GB	Castlewood	Rigid (magnetic)	2.2GB	Discontinued	11
Orb 5.7GB	Castlewood	Rigid (magnetic)	5.7GB	Discontinued	11, 12
Peerless	Iomega	Rigid (magnetic)	10GB	Discontinued	13
Peerless	Iomega	Rigid (magnetic)	20GB	Discontinued	13

1. Originally known as *Clik!* Media available from Iomega (www.iomega.com).

2. Media available from Iomega (www.iomega.com) and Fujifilm (www.fujifilm.com).

3. Media available from Maxell (www.maxell.com).

4. Read/write compatible with standard 720KB and 1.44MB 3 1/2" floppy disks.

5. Supports special 32MB format for 1.44MB 3 1/2" floppy disks.

6. Drive read-write compatible with Zip 100 media.

7. Drive read-write compatible with Zip 250 media; read-compatible with Zip 100 media.

8. Limited tech support, drive and media availability from SYQT, Inc. (www.syquest.com); see website for support and media availability for older SyQuest products (SyJet, others).

9. Media available from Iomega (www.iomega.com).

10. Read/write compatible with 1GB Jaz media.

11. No support available from manufacturer; some stores still have media and drives. Check DriverGuide (www.driverguide.com) or other websites for drivers.

12. Read-compatible with 2.2GB Orb media.

13. Drivers available from Iomega (www.iomega.com); some stores still have media and drives.

Iomega Zip

Although Iomega Zip drives are no longer as popular as they were in the late 1990s, their widespread industry adoption and easy media and drive availability make them the leading andwith the demise of SuperDiskthe only bigger-than-floppy magnetic removable-media storage de facto standard. Various

models can be purchased as upgrades for existing computers, and media is available from both Iomega and Fujifilm.

Unlike the LS-120 and LS-240 SuperDisk drives, the Iomega Zip drive can't use standard 3 1/2" floppy disks. It is a descendent of a long line of removable-media drives from Iomega that go back to the first Bernoulli cartridge drives released in the early 1980s.

Note

For more information about Iomega Bernoulli drives, see *Upgrading and Repairing PCs, 14th Edition*, available in electronic form on the disc packaged with this book.

The current form of Bernoulli-technology drive from Iomega is the popular Zip drive. These devices are available in 100MB, 250MB, and 750MB versions with either ATAPI (internal), USB (external), or FireWire (external) interfaces. They also sell specific external models with either SCSI or parallel port interfaces. In addition, low-power PC Card or internal drive bay versions are available from various aftermarket vendors designed for use in notebook computers.

Zip 100 drives can store up to 100MB of data on a small removable magnetic cartridge that resembles a 3 1/2" floppy disk. The newer Zip 250 drives store up to 250MB of data on the same size cartridge and can read and write to the Zip 100 cartridges. The most recent Zip drive holds 750MB of data. It's available in separate ATAPI internal versions for PC and Mac and in USB 2.0 and FireWire (IEEE 1394a) versions for use with both platforms. It has read/write compatibility with Zip 250 media, but it has read-only compatibility with Zip 100 media. For best performance, you should use the native media size with Zip 250 and Zip 750 drives; these drives read and write much more slowly when smaller Zip media is used than when their native media size is used.

For more information about Zip drives, see the Technical Reference section of the disc packaged with this book.

Iomega REV

Iomega REV was introduced in 2004. It is designed to be used in several ways:

- *Backup.* REV provides capacity comparable to that of DAT 72 or DLT VS80 tape drives while providing faster read and write access.
- *Primary storage.* REV can be used as a bootable hard disk. The drive supports all common internal and external interfaces (see [Table 10.6](#)).
- *Additional storage.* REV cartridges use a rigid removable disk (RRD) design that provides a sealed, air-filtered environment for read/write heads and electronics and a spin rate of 4,200RPM, which is comparable to many notebook computer hard disks.

REV uses 35GB hard-disktype removable-media cartridges. In drag-and-drop file transfer tests, REV drives offer comparable transfer rates to 30GB ATA/IDE hard disks with files up to 64KB in size, and they are much faster with files of 1MB or larger. The maximum data transfer is up to 25MBps.

Iomega REV Capacity

The native capacity of any Iomega REV drive is 35GB. Iomega claims a maximum compressed capacity of 90GB (2.6:1), based on testing performed with the Calgary Corpus data set. However, most users will not see this level of data compression in most real-world operations. The reason is that the files used in the Calgary Corpus were primarily text files. As you'll learn if you spend any time using PKZip, WinZip, or the built-in Zip-compatible Windows XP archiving feature, text files can be compressed up to 90% smaller than normal. However, a great deal of the data on today's systems is already compressed data, such as JPEG photos, PDF files, MP3 and WMA audio files, Zip and cab archives, and so forth. A better estimate for compression performance is to assume a maximum capacity of 70GB (2:1 compression), as is assumed by most third-party backup products.

Note

The Calgary Corpus data set was developed in 1990 by Tim Bell and Ian Witten. It can be downloaded from www.data-compression.info/Corpora/CalgaryCorpus/.

A newer data set used for compression testing is the Canterbury Corpus. It can be downloaded from <http://corpus.canterbury.ac.nz/index.html>. This corpus was developed in 1997. You might want to try both with your favorite backup or archiving programs to see how the results differ.

Iomega REV Drives

Iomega offers a wide variety of drive interfaces for REV, enabling you to choose a drive for almost any type of internal or external host adapter. [Table 10.6](#) lists available models. Note that all drives include Iomega Automatic Backup Pro for Windows 2000 and XP.

Table 10.6. Iomega REV Drive Versions

Interface	Form Factor	Third-Party Backup Software Included
USB 2.0	Desktop	
ATA/IDE (ATAPI)	3 1/2" or 5 1/4" internal	
1394a/FireWire 400 ^[1]	Desktop	Dantz Retrospect Express for Mac
SCSI external ^[2]	Desktop	Yosemite TAPEWARE for REV
SCSI internal ^[2]	3 1/2" or 5 1/4" internal	Yosemite TAPEWARE for REV
SATA internal	3 1/2" or 5 1/4" internal	

^[1] Compressed capacity of 70GB when Dantz Retrospect Express is used

^[2] *Ultra160 LVD interface*

Adaptations of Iomega REV Technology

Iomega REV is not just a PC-based backup and storage technology. Iomega manufactures a 10-cartridge autoloader known as the REV Autoloader 1000 for servers. It includes CA Brightstor ARCserve Backup OEM edition for a single server, and it connects to a server via a 68-pin LVD SCSI connection. Options include a bar code reader, a remote management unit, and 2U rack-mounted hardware.

Thomson (www.thomson.net) has adapted the Iomega REV for IT-based video recording purposes as part of its Grass Valley Infinity line of DV camcorder and recorder products introduced in 2005. These devices also use a new version of the REV cartridge known as the REV PRO as well as solid-state Compact Flash memory for video recording.

Magneto-Optical Drives

One of the most neglected types of removable-drive technologies is the magneto-optical (MO) drive. Introduced commercially in 1985, magneto-optical drives are now available in capacities exceeding 9GB.

Two sizes of magneto-optical media and drives are available for desktop computers: 3 1/2" and 5 1/4". The 3 1/2" drives have capacities up to 2.3GB, and the 5 1/4" drives have capacities up to 9.1GB. 12" MO drives are also available for enterprise systems. Originally, magneto-optical drives were strictly WORM (write once, read many) drives that produced media that could be added to but not erased. WORM drives are still available on the market, but for desktop computer users, read/write MO drives are preferable.

Magneto-Optical Technology

At normal temperatures, the magnetic surface of an MO disk is very stable, with archival ratings of up to 30 years.

One surface of an MO disk faces a variable-power laser, whereas the other surface of the disk faces a magnet. Both the laser beam and the magnet are used to change the data on an MO disk. [Figure 10.9](#) illustrates the magneto-optical writing and reading process.

Figure 10.9. Magneto-optical drives use the laser at high power to heat the magnetic surface to enable its contents to be magnetically changed during the write cycle (left) and use the laser at low power to determine the angle of polarization (the Kerr effect) during the read cycle (right).

[\[View full size image\]](#)

Write Cycle

Read Cycle

The "optical" portion of an MO drive is the laser beam, which is used at high power during the erasing process to heat the destination area of the MO drive to a temperature of about 200° Celsius (the Curie point, at which a normally magnetic surface ceases to be magnetic). This enables any existing information in that area to be erased by a uniform magnetic field, which doesn't affect the other portions of the disk that are at normal temperature.

Next, the laser beam and magnetic field are used together to write information to the location by applying high power to the laser and applying a controlled magnetic signal to the media to change it to either a binary 0 or 1.

During the read process, the laser is used at low power to send neutrally polarized light to the surface of the MO disk. The areas of the MO disk that store binary 0s reflect light at a polarization angle different from those that store binary 1s. This difference of one degree is called the *Kerr effect*.

In older MO drives, the erase and write process involved two separate operations, but most recent MO drives starting with the Plasmon DW260 of 1997 use the LIMDOW method (light intensity modulated direct overwrite) for a single-pass operation with some media types. LIMDOW drives use magnets built in to the disk itself, rather than separate magnets as in older MO drives. LIMDOW drives are fast enough to store MPEG-2 streaming video and make achieving higher capacities easier.

MO drives are available from many manufacturers at a variety of price points.

Most internal MO drives connect to SCSI interfaces. ATAPI/IDE models are sold by some vendors but aren't as easy to find, and external MO drives are available in SCSI, USB 2.0, and IEEE 1394a interfaces.

Comparing MO to "Pure" Magnetic Media

Compared to most high-capacity removable-media drives, MO drive hardware is more expensive (especially in the 5 1/4" media size), but media costs are far less per MB, durability is far better, and performance is as good as or better than the 200MB-or-under class magnetic removable-media drives. The use of SCSI interfaces for most models was a drawback when MS-DOS/Windows 3.1 were the leading operating systems, but Windows 9x/Me/NT/2000/XP have much easier SCSI installation processes, and SCSI interfaces have dropped in price (and are included with some internal drives). IEEE 1394a and Hi-Speed USB (USB 2.0) interfaces available on some models allow the easiest installation process of all for external drives. If you can afford the high initial cost of the 5 1/4" media MO drives, you'll have a fairly fast, durable, long-term storage solution that's also a good storage area for works in progress.

Flash Memory Devices

Flash memory has been around for several years as a main or an auxiliary storage medium for notebook computers. However, the rise of devices such as digital cameras and MP3 players and the presence of USB ports on practically all recent systems have transformed this technology from a niche product into a mainstream must-have storage technology.

Flash memory is a type of nonvolatile memory that is divided into blocks rather than bytes, as with normal RAM memory modules. Flash memory, which also is used in most recent computers for BIOS chips, is changed by a process known as *Fowler-Nordheim tunneling*. This process removes the charge from the floating gate associated with each memory cell. Flash memory then must be erased before it can be charged with new data.

The speed, low reprogramming current requirements, and compact size of recent flash memory devices have made flash memory a perfect counterpart for portable devices such as notebook computers and digital cameras, which often refer to flash memory devices as so-called "digital film." Unlike real film, digital film can be erased and reshot. Ultra-compact, USB-based keychain drives that use flash memory are replacing both traditional floppy drives and Zip/SuperDisk drives for transporting data between systems.

Types of Flash Memory Devices

Several types of flash memory devices are in common use today, including

- ATA Flash
- CompactFlash (CF)
- SmartMedia (SM)
- MultiMediaCards (MMC)
- Reduced Size MMC (RS-MMC)
- SecureDigital (SD)
- MiniSD
- Memory Stick
- Memory Stick PRO
- Memory Stick PRO Duo
- xD-Picture Card
- Thumb or keychain USB devices

Some of these are available in different sizes (Type I/Type II). [Table 10.7](#) shows the various types of solid-state storage used in digital cameras and other devices, listed in order of introduction.

Table 10.7. Different Flash Memory Devices and Physical Sizes

Type	L (mm)	W (mm)	H (mm)	Volume (cc)	Date Introduced
ATA Flash Type II	54.00	85.60	5.00	23.11	Nov. 1992

ATA Flash Type I	54.00	85.60	3.30	15.25	Nov. 1992
CompactFlash (CF) Type I	42.80	36.40	3.30	5.14	Oct. 1995
SmartMedia (SM)	37.00	45.00	0.76	1.27	Apr. 1996
CompactFlash (CF) Type II	42.80	36.40	5.00	7.79	Mar. 1998
Memory Stick	21.45	50.00	2.80	3.00	Jul. 1998
Secure Digital (SD)	24.00	32.00	2.10	1.61	Aug. 1999
MultiMediaCard (MMC)	24.00	32.00	1.40	1.08	Nov. 1997
xD-Picture Card (xD)	20.00	25.00	1.70	0.85	Jul. 2002
Memory Stick Duo	20.00	31.00	1.6	0.99	Jul. 2002
Reduced Size MMC (RS-MMC)	24.00	18.00	1.40	0.60	Nov. 2002
MiniSD	20.00	21.5	1.4	0.59	Mar. 2003
MicroSD	15.00	11.00	1.0	0.165	Jul. 2005
Memory Stick Micro	15.00	12.5	1.2	0.225	Sep. 2005

Note: USB flash drives are not listed because they do not have a standardized form factor.

CompactFlash

CompactFlash was developed by SanDisk Corporation in 1994 and uses ATA architecture to emulate a disk drive; a CompactFlash device attached to a computer has a disk drive letter just like your other drives. Later types of flash memory also use ATA architecture, either implemented in the device itself or in its controller.

The original size was Type I (3.3mm thick); a newer Type II size (5mm thick) accommodates higher-capacity devices. Both CompactFlash cards are 1.433" wide by 1.685" long, and adapters allow them to be inserted into notebook computer PC Card slots. The CompactFlash Association (<http://www.compactflash.org>) oversees development of the standard.

SmartMedia

Ironically, SmartMedia (originally known as SSFDC for solid state floppy disk card) is the simplest of any flash memory device; SmartMedia cards contain only flash memory on a card without any control circuits. This simplicity means that compatibility with different generations of SmartMedia cards can require manufacturer upgrades of SmartMedia-using devices. The Solid State Floppy Disk Forum (<http://www.ssfdc.or.jp/english>) oversees development of the SmartMedia standard.

Tip

If you use a SmartMedia-based Olympus digital camera that has the panorama feature, be sure to use Olympus-brand SmartMedia because other brands lack support for the panorama feature.

MultiMediaCard

The MultiMediaCard (MMC) was codeveloped by SanDisk and Infineon Technologies AG (formerly Siemens AG) in November 1997 for use with smart phones, MP3 players, digital cameras, and camcorders. The MMC uses a simple 7-pin serial interface to devices and contains low-voltage flash memory. The MultiMediaCard Association (www.mmca.org) was founded in 1998 to promote the MMC standard and aid development of new products. In November 2002, MMCA announced the development of the Reduced Size MultiMediaCard (RS-MMC), which reduces the size of the standard MMC by about 40% and can be adapted for use with standard MMC devices. The first flash memory cards in this form factor were introduced in early 2004 to support compact smart phones.

SecureDigital

A SecureDigital (SD) storage device is about the same size as MMC (many devices can use both types of flash memory), but it's a more sophisticated product. SD, which was codeveloped by Toshiba, Matsushita Electric (Panasonic), and SanDisk in 1999, gets its name from two special features. The first is encrypted storage of data for additional security, meeting current and future Secure Digital Music Initiative (SDMI) standards for portable devices. The second is a mechanical write-protection switch. The SD slot can also be used for adding memory to Palm PDAs. The SDIO standard was created in January 2002 to enable SD slots to be used for small digital cameras and other types of expansion with various brands of PDAs and other devices. The SD Card Association (<http://www.sdcard.org>) was established in 2000 to promote the SD standard and aid the development of new products. Note that some new laptop computers have built-in SD slots.

Reduced-size versions of SD include MiniSD (introduced in 2003) and MicroSD (introduced in 2005). MiniSD and MicroSD are very popular choices for smart phones, and can be adapted to a standard SD slot. MicroSD is compatible with the TransFlash standard for mobile phones.

Sony Memory Stick and Memory Stick Pro

Sony, which is heavily involved in both notebook computers and a wide variety of digital cameras and camcorder products, has its own proprietary version of flash memory known as the Sony Memory Stick. This device features an erase-protection switch, which prevents accidental erasure of your photographs. Sony has also licensed Memory Stick technology to other companies, such as Lexar Media.

Lexar introduced the enhanced Memory Stick PRO in 2003, with capacities ranging from 256MB up to 1GB. Memory Stick Pro includes MagicGate encryption technology, which enables digital rights management, and Lexar's proprietary high-speed memory controller. Memory Stick Pro is sometimes referred to as MagicGate Memory Stick.

The Memory Stick Pro Duo is a reduced-size, reduced-weight version of the standard Memory Stick Pro. It can be adapted to devices designed for the Memory Stick Pro.

ATA Flash PC Card

Although the PC Card (PCMCIA) form factor is now used for everything from game adapters to modems, from SCSI interfacing to network cards, its original use was computer memory, as the old PCMCIA

(Personal Computer Memory Card International Association) acronym indicated.

Unlike normal RAM modules, PC Card memory acts like a disk drive, using the PCMCIA ATA (AT Attachment) standard. PC Cards come in three thicknesses (Type I is 3.3mm, Type II is 5mm, and Type III is 10.5mm), but all are 3.3" long by 2.13" wide. Type I and Type II cards are used for ATA-compliant flash memory and the newest ATA-compliant hard disks. Type III cards are used for older ATA-compliant hard disks; a Type III slot also can be used as two Type II slots.

xD-Picture Card

In July 2002, Olympus and Fujifilm, the major supporters of the SmartMedia flash memory standard for digital cameras, announced the xD-Picture Card as a much smaller, more durable replacement for SmartMedia. In addition to being about one-third the size of SmartMedia making it the smallest flash memory format yet xD-Picture Card media has a faster controller to enable faster image capture. Currently, xD-Picture Cards are available in capacities of 16MB-1GB.

16MB and 32MB cards (commonly packaged with cameras) record data at speeds of 1.3MBps, whereas 64MB and larger cards record data at 3MBps. The read speed for all sizes is 5MBps. The media is manufactured for Olympus and Fujifilm by Toshiba, and because xD-Picture media is optimized for the differences in the cameras (Olympus's media supports the panorama mode found in some Olympus xD-Picture cameras, for example), you should buy media that's the same brand as your digital camera.

USB Keychain Drives

As an alternative to floppy and Zip/SuperDisk-class removable-media drives, USB-based flash memory devices are rapidly becoming the preferred way to move data between systems. The first successful drive of this type Trek's ThumbDrive was introduced in 2000 and has spawned many imitators, including many that incorporate a keychain or pocket clip to emphasize their portability.

Note

Some USB flash memory drives are even built in to pens or knives, such as the Victorinox SwissMemory Swiss Army Knife, with capacities up to 1GB.

Unlike other types of flash memory, USB keychain drives don't require a separate card reader; they can be plugged in to any USB port or hub. Although a driver is usually required for Windows 98 and Windows 98SE, most USB keychain drives can be read immediately by newer versions of Windows, particularly Windows XP. As with other types of flash memory, USB keychain drives are assigned a drive letter when connected to the computer. Most have capacities ranging from 128MB to 1GB, with some capacities as high as 2GB or more. However, typical read/write performance of USB 1.1-compatible drives is about 1MBps. Hi-Speed USB keychain drives are much faster, providing read speeds ranging from 5MBps to 15MBps and write speeds ranging from 5MBps to 13MBps. Because Hi-Speed USB keychain drives vary in performance, be sure to check the specific read/write speeds for the drives you are considering before you purchase one.

Tip

If you have a card reader or scanner plugged in to a USB hub or port on your computer, you might need to disconnect it before you can attach a USB keychain drive. This is sometimes

necessary because of conflicts between the drivers used by some devices. Use the Windows Safely Remove Hardware icon in the system tray to stop the card reader before you insert the USB keychain drive. After the USB keychain drive has been recognized by the system, you should be able to reattach the card reader.

For additional protection of your data, some USB keychain drives have a mechanical write-protect switch. Others include or support password-protected data encryption as an option, and some are capable of being a bootable device (if supported in the BIOS). The Kanguru MicroDrive+ can be upgraded with SD or MMC flash cards for additional capacity. Some drives feature biometric security; your fingerprint is the key to using the contents of the drive, whereas others include more traditional security software.

If you use MMC, SD, xD-Picture Card, Memory Stick, or Memory Stick Pro flash memory cards in digital cameras or other devices, you can use them as interchangeable storage in the Lexar Media Single-Slot Multi-Card Reader. This device is essentially a USB (1.1/2.0) keychain drive without flash memory storage onboard. You can use it as a card reader or as a USB drive with removable storage.

Note

Older models of the Lexar Single-Slot Multi-Card Reader were sold as the Jump Drive Trio and supported MMC, SD, or Memory Stick media only.

SimpleTech's Bonzai USB 2.0 flash drive provides similar functionality for SD and MMC cards only and is available with or without preinstalled SD or MMC memory.

Comparing Flash Memory Devices

As with any storage issue, you must compare each product's features to your needs. You should check the following issues before purchasing flash memory-based devices:

- *Which flash memory products does your camera or other device support?* Although adapters allow some interchange of the various types of flash memory devices, for best results, you should stick with the flash memory type your device was designed to use.
- *Which capacities does your device support?* Flash memory devices are available in ever-increasing capacities, but not every device can handle the higher-capacity devices. Check the device and flash memory card's websites for compatibility information.
- *Are some flash memory devices better than others?* Some manufacturers have added improvements to the basic requirements for the flash memory device, such as faster write speeds and embedded security. Note that these features usually are designed for use with particular digital cameras only. Don't spend the additional money on enhanced features if your camera or other device can't use those features.

Only the ATA Flash cards can be attached directly to a notebook computer's PC Card slots. All other devices need their own socket or some type of adapter to transfer data. [Figure 10.10](#) shows how the most common types of flash memory cards compare in size to each other and to a penny.

Figure 10.10. SmartMedia, CompactFlash, MultiMediaCard, SecureDigital, xD-

Picture Card, and Sony Memory Stick flash memory devices. Shown in relative scale to a U.S. penny (lower right).

[Table 10.8](#) provides an overview of the major types of flash memory devices and their current capacities. Note that smaller-capacity cards might be bundled with some digital cameras.

Table 10.8. Flash Memory Card Capacities

Device	Minimum Capacity	Maximum Capacity	Notes
CompactFlash+	16MB	8GB	Highest capacity; most flexible format; supported by most digital SLR cameras. Lexar Media and SanDisk also make faster versions of CF+ media; Lexar Media also makes LockTight secured access media.
SmartMedia	16MB	128MB	Popular choice for older Fujifilm and Olympus digital cameras.
MultiMediaCard (MMC)	16MB	128MB	MMC cards can work in most SD slots.
RS-MMC	128MB	1GB	Use adapter to plug in to MMC slots.

Secure Digital (SD)	16MB	1GB	SD cards do not work in MMC slots. Used by most brands of consumer-level digital cameras.
MiniSD	128MB	1GB	Use adapter to plug in to SD slots.
MicroSD	128MB	128MB	Use adapter to plug in to SD slots.
Memory Stick	16MB	128MB	This was developed by Sony and licensed to other vendors.
Memory Stick PRO (also known as Memory Stick Magic Gate)	256MB	1GB	This is the enhanced high-speed version of Memory Stick (also known as with digital rights management support).
Memory Stick Pro Duo	256MB	512MB	Reduced-size version of Memory Stick PRO.
ATA Flash	16MB	2GB	This plugs directly into a PC Card (PCMCIA) slot without an adapter.
xD-Picture Card	16MB	1GB	Use the same brand as your digital camera for the best results.
USB keychain drive	16MB	2GB	Some include password-protection and write-protect features.

I normally recommend devices (cameras, PDAs, and so on) that use CompactFlash (CF), Secure Digital (SD), or xD-Picture flash memory cards. Any of the others I generally do not recommend due to limitations in capacity, performance, proprietary designs, and higher costs.

CompactFlash is the most widely used format in professional and consumer devices and offers the highest capacity, at the lowest prices, in a reasonably small size. CF cards plug directly into PC Card slots on all laptops by using a simple passive adapter that is extremely inexpensive. Therefore, when you're not using one of those cards in your camera, you can use it as a solid-state hard disk in a laptop. For a long time I would not even consider a camera or other device that did not use CF storage. I have relaxed on that stance a little bit, but it is still by far the best overall format and is available in capacities of up to 8GB or higher. It is also significantly faster than the other formats.

Secure Digital has become quite popular, is reasonably fast, and is available in capacities up to 1GB. SD sockets also take MultiMediaCard (MMC) cards, which are basically thinner versions of SD. Note that the opposite is not true—MMC sockets do not accept SD cards. MMC is also available in versions up to 128MB; the MMC Mobile developed by SanDisk reaches capacities of 256MB. Finally, xD-Picture is a very compact format that has grown in popularity and offers capacities up to 1GB.

In general I would not consider any device that uses other formats, especially Memory Stick, which is a Sony proprietary format (didn't Sony learn anything from the Betamax versus VHS war?). The RS-MMC format is too new to consider and as such is found in a limited number of devices with very limited capacity. ATA Flash is great, but the cards are physically big, mostly obsolete, and can easily be replaced by a CompactFlash card in a PC Card adapter. SmartMedia was once a popular format, but it's relatively fragile now and is limited to 128MB in capacity, and camera vendors who once used it have now switched to the higher-capacity xD-Picture card format.

Moving Data in Flash Memory Devices to Your Computer

Several types of devices can be purchased to enable the data on flash memory cards to be moved from digital cameras and other devices to a computer. Although some older digital cameras come with an RS-232 serial cable for data downloading, this is a painfully slow method, even for low-end cameras with less than a megapixel (1,000 pixel horizontal width) resolution.

Card Readers

The major companies who produce flash card products sell card readers that can be used to transfer data from proprietary flash memory cards to PCs. These card readers typically plug in to the computer's USB ports (some older versions might use the parallel port) for fast access to the data on the card.

In addition to providing fast data transfer, card readers enable the reuse of expensive digital film after the photos are copied from the camera and save camera battery power because the camera is not needed to transfer information. External card readers can be used with any computer with the correct port type and a supported operating system. USB readers, for example, should be used with Windows 98 or above. Some older readers don't support write functions (such as erasing pictures after they're transferred from the media to your computer); I recommend devices with read/write functionality.

Because many computer and electronics device users might have devices that use two or more types of flash memory, many vendors now offer multifORMAT flash memory card readers, such as the SanDisk 12-in-1 Card Reader/Writer shown in [Figure 10.11](#).

Figure 10.11. The SanDisk 12-in-1 Card Reader/Writer plugs into a Hi-Speed USB (USB 2.0) port and features a removable stand. *Photo courtesy of SanDisk.*

Before you purchase a card reader, check your PC and your photo printer. You might already have a card reader built in to your PC or photo printer. Many PCs, including those that use Windows XP Media Center Edition, include a three- or four-slot card reader built in to the front panel. This type of card reader plugs into a USB port header on the motherboard.

[Figure 10.12](#) shows the integrated card reader built in to an Epson Stylus Photo R300 printer. A Compact Flash card is inserted into the printer.

Figure 10.12. A three-slot card reader built in to an Epson Stylus Photo R300 inkjet printer.

Type II PC Card Adapters

For use in the field, you might prefer to adapt flash memory cards to the Type II PC Card or CardBus slot found in most notebook computers. You insert the flash memory into the adapter; then, you slide the adapter into the notebook computer's Type II PC Card slot. [Figure 10.13](#) shows how a CompactFlash card Type II PC Card adapter works. As with card readers, check with the major companies that produce your type of flash memory device for the models available.

Figure 10.13. A typical Type II PC Card adapter for CompactFlash media (left) compared to an ATA DataFlash card (right).

Key Factors in Selecting a Removable-Media Drive

When shopping for a removable-media drive, keep the following in mind:

- *Price per megabyte/gigabyte of storage.* Take the cost of the drive's cartridge or disk and divide it by the storage capacity to see how much you are paying per megabyte or gigabyte of storage. This difference in price becomes quite apparent as you buy more cartridges or disks for the drive. (Don't forget to factor in the cost of the drive itself if you are trying to decide which removable-media drive to buy!) If you plan to use removable storage for temporary data storage only, as with flash memory devices, the cost per megabyte or gigabyte is a less important factor than if you plan to leave data on a cartridge or disk for long periods of time.
- *Access time versus need of access.* The access and data transfer speeds are important only if you need to access the data frequently or quickly. If your primary use is archiving data, a slower drive might be fine. However, if you plan to run programs off the drive, choose a faster drive instead.
- *Compatibility and portability.* For maximum portability and compatibility, opt for a USB-based solution. Although some removable-media drives also support FireWire (IEEE 1394), SCSI or parallel ports, Hi-Speed USB is the lowest-cost and friendliest solution because it's built in to recent systems, supports hot-swapping, and can be used on machines with USB 1.1 ports (albeit with much slower data transfer and access speeds). Also verify that drivers are available for each type of machine and operating system you want to use with the drive, and consider whether you need to exchange disks with other users. If you don't want the expense of buying a separate drive for each machine, USB keychain storage devices using flash memory or USB-based external hard disks can

perform the same tasks and don't need a separate drive for each computer. For some users, this might be the most important factor in choosing a drive.

- *Storage capacity.* For maximum safety and ease of use, the capacity of your storage device should be the largest available that meets your other requirements. Digital camera users, for example, will want the largest possible flash or disk storage supported by their cameras to allow more photos or higher-quality photos to be stored. Desktop and notebook computer users will want the largest drives possible for data backup or program storage.

Note

For many uses, the rewritable DVD drive is the best choice for two reasons: low media cost (well under \$1 each in quantity for CD-RW media; less than \$3 each for rewritable DVD) and near-universal compatibility (virtually all systems sold since the mid-1990s can read CD-RW media in ordinary CD-ROM drives, and many systems with DVD-ROM drives can read rewritable DVD media). For permanent storage, use CD-R or recordable DVD media.

USB keychain drives are now available in capacities above 1GB for situations demanding high storage density in a very small space.

- *Internal versus external.* Most users find external USB drives the easiest to install; additionally, they give you the option of using the drive on several systems. Internal drives are usually faster because of their ATA, Serial ATA, or SCSI interfaces and are more cleanly integrated into the system from a physical perspective.
- *Bootable or not.* Most systems dating from 1995 or later have a BIOS that supports the Phoenix El Torito standard, which enables them to boot from CD or DVD drives or drives that emulate them, such as the Iomega REV. Most also support the ATAPI/IDE version of the Imation LS-120 or LS-240 SuperDisk as a bootable device; however, those drives are obsolete and difficult to find. Some systems support ATA Zip drives as a bootable drive, but Zip drives are a proprietary format and incompatible with standard 3 1/2" floppy disks. The newest systems support USB floppy drives for booting, enabling you to dispense with a traditional internal floppy disk drive for diagnostics or mass storage device driver installation.

Use the Disk Management snap-in module in Windows 2000 and Windows XP to change the drive letter assigned by Windows to a removable-media drive. With older versions of Windows, the next available drive letter will be assigned and cannot be changed.

Microdrive Technology

If you prefer magnetic storage for digital camera or other electronic device data storage, consider the Hitachi Microdrive, originally developed by IBM and now manufactured and sold by Hitachi Global Storage Technologies. The Hitachi Microdrive has also been sold by various other companies under OEM agreements. The Microdrive is a true hard disk that spins at 3,600RPM and features a 128KB cache buffer.

Since its introduction by IBM, the Microdrive in its Compact Flash Type II-compatible form factor has increased in capacity from 170MB up to 6GB. [Table 10.9](#) compares the specifications for current Microdrive models that use Compact Flash (CF) Type II interfaces. These drives are available in travel kits and can be used with many digital cameras and other devices that are compatible with Compact Flash Type II cards.

Table 10.9. Hitachi Microdrives in Compact Flash Type II Interface

Specifications	3K4-2	3K6-3	3K6-4	3K6-4	3K6-6
Model number	HMS360402D5CF00	HMS360603D5CF00	HMS360404D5CF00	HMS360604D5CF00	HMS360606D5CF00
Capacity	2GB	3GB	4GB	4GB	6GB
Seek time (ms)	12ms	12ms	12ms	12ms	12ms
Media transfer rate	97.9Mbps	125Mbps	97.9Mbps	125Mbps	125Mbps
Interface transfer rate (maximum)	33MBps	33MBps	33MBps	33MBps	33MBps
Sustained data transfer rate	4.3MBps7.2MBps	4.9MBps9.4MBps	4.3MBps7.2MBps	4.9MBps9.4MBps	4.9MBps9.4MBps
Operating shock	200G (2ms)	200G (2ms)	200G (2ms)	200G (2ms)	200G (2ms)
Nonoperating shock	2,000G (1ms)	2,000G (1ms)	2,000G (1ms)	2,000G (1ms)	2,000G (1ms)

All Microdrives using the CF Type II interface, including the current 3K4 and 3K6 models shown in [Table 10.9](#), weigh 16g with dimensions of 42.8x36.4x5mm.

Tip

Hitachi uses a standard formula for its Microdrive model numbers. Use this information to quickly identify the features of a particular Microdrive model.

For example, a Microdrive with a model number of HMS361008M5CE00 has the following features:

H = Hitachi

M = Generation code (D = earlier generation)

M = Microdrive

S = Standard

36 = 3600RPM

10= Reserved (also 04, 06)

08 = Capacity 8GB (06 = 6GB, 04 = 4GB, 03 = 3GB) 0 = Reserved

5 = 5mm z - height

CE = ZIF connector PATA interface (CA = CE-ATA)

CM = ATA on MMC (CF = Compact Flash Type II)

0 = Reserved

0 = Reserved

The new 3K8 Microdrive series for embedded applications has capacities of 6GB and 8GB. The 3K8 series uses a ZIF connector to interface to PATA, CE-ATA, or ATA on MMC interfaces in devices such as mobile phones and ultra-small consumer electronics devices. Despite its higher capacity, the 3K8 actually has a smaller form factor than the 3K6 and previous Microdrive generations: It weighs just 13g, with dimensions of 40x30x5mm. The 3K8 series also features increased shock resistanceit can handle an operational shock of up to 400G (2ms).

Areal density has increased with each Microdrive generation, from as little as 5.04Gb/square inch with the original 170MB model up to 119Gb/square inch in the 3K8 series. In 4GB and larger drives, Hitachi uses a five-layer version of the Pixie Dust AFC media technology originally developed by IBM. To enable the increased areal density to be used as completely as possible, Hitachi also developed smaller hard disk read/write head technology.

Starting in 2003, Hitachi began to use femto sliders for the read/write heads used in several small hard disk series, including the Microdrive 3K6 and 3K8 as well as the Travelstar 7K60, E7K60, 7K100, E7K100, and C4K60 Slim drives. Femto sliders are only 20% of the size of the pioneering Mini hard disk slider introduced in 1980.

See the www.hitachigst.com website for more information about Microdrive products, a compatibility matrix, and other information.

Tape Drives

The data backup and archive needs of a personal computer can be overwhelming. People with large hard drives and numerous applications installed and those who generate a large amount of data might need to back up their computers on a weekly or even a daily basis.

In addition, a critical need on today's PCs is data storage space. Sometimes it seems as though the storage requirements of a PC can never be satisfied. On nearly any PC used for business, study, or even fun, the amount of software installed can quickly overwhelm even a large hard drive. To save space on the primary storage devices, you can archive infrequently used data to another storage medium. Depending on the method you use for archiving data to secondary storage, you might be able to read the data directly from the device, or you might need to restore the data to the drive before you can access it. If you copy data to the drive with drag-and-drop, the data can be read from the media directly. However, if you use a backup program to create the backup, you will need to use that same program to access the data and restore it to a drive before it can be reused.

Historically, a popular method for backing up full hard disks or modified files has been a tape backup drive. This section focuses on current tape backup drive technologies to help you determine whether this type of storage technology is right for you.

Tape backup drives are the most simple and efficient devices for creating a full backup of your hard disk if the tape is large enough. With a tape backup drive installed on your computer, you insert a tape into the drive, start your backup software, and select the drive and files you want to back up. The backup software copies your selected files onto the tape while you attend to other business. Later, when you need to retrieve some or all of the files on the backup tape, you insert the tape into the drive, start your backup program, and select the files you want to restore. The tape backup drive takes care of the rest of the job.

This section examines the various types of tape backup drives on the market, describing the capacities of different drives as well as the system requirements for installation and use of a tape drive. The following topics are covered in this section:

- Hard-diskbased alternatives to tape backup
- Advantages and disadvantages to tape backup
- Common standards for tape backup drives
- Common backup tape capacities
- Newer higher-capacity tape drives
- Common tape drive interfaces
- Portable tape drives
- Tape backup software

Hard-DiskBased Alternatives to Tape Backup

Before you decide to adopt a tape backup as your backup strategy, keep the following alternatives in mind:

- *External hard drives.* Maxtor, Western Digital, Seagate, SimpleTech, and others have developed external hard drives with capacities up to 500GB. These drives attach through USB 1.1, USB 2.0, or IEEE 1394a ports and can be used for data backup with backup software or drag-and-drop file copying. Many external drives include backup software, and some offer additional features such as one-button backup, flash memory card readers, and a Hi-Speed USB (USB 2.0) hub.

- *Removable-media drives based on hard disk technology.* The Iomega REV drive's native capacity of 35GB per cartridge and compressed capacity of up to 90GB per cartridges makes it a promising alternative to tape backup drives.

◀◀ To learn more about the Iomega REV, see "[Iomega REV](#)," p. [692](#).

- *RAID arrays.* By connecting identical hard disks to a RAID array using RAID 1 data mirroring, RAID 0 +1 (RAID 10) data striping plus mirroring, or RAID 5 data striping with parity, your data is automatically backed up as soon as it is created. RAID arrays were once used strictly for SCSI drives on networks because of their high cost. However, recent developments in high-performance, low-cost, RAID 1 and RAID 0+1-compatible ATA or Serial ATA host adapters on motherboards and PCI add-on cards make this another useful backup strategy to consider. RAID 5 arrays generally require a separate host adapter.

◀◀ To learn more about RAID, see "[ATA RAID](#)," p. [596](#).

Disadvantages of Tape Backup Drives

Many computer users who once used tape backups for data backup purposes have turned to other technologies for the following reasons:

- *Creating a tape backup copy of files or of a drive requires the use of a special backup program in almost all cases.* A few tape drives allow drive letter access to at least part of the tape capacity, but this feature is far from universal, and a special driver program must be used.
- *Retrieving data from most tape backup drives requires that the data files be restored to the hard disk.* Other types of backup storage can be treated as a drive letter for direct use from the media.
- *Tape backups store and retrieve data sequentially.* The last file backed up can't be accessed until the rest of the tape is read; other types of backup storage use random access, which enables any file on the device to be located and used in mere seconds.
- *Low-cost tape backups using QIC (Quarter Inch Committee), QIC-Wide, or Travan technology once had little problem keeping up with increases in hard disk capacity and once sold for prices comparable to or less than the hard disks they protected.* Today's hard disks have capacities up to 500GB or larger and are far less expensive than most comparably sized tape backups. As a result, more expensive, higher-capacity tape drives are needed to achieve single-cartridge backups. Otherwise, you must load multiple tapes manually or use an autoloader.
- *Newer backup and restore techniques, such as drive imaging/ghosting, rival the ease of use of tape backups and permit data restoration with lower-cost optical storage devices such as rewritable DVD drives.* These alternatives are particularly useful if only a few GB of data need to be backed up on a continuing basis.

For these reasons, the once-unassailable position of a tape backup drive as being the must-have data protection accessory is no longer a secure one; plenty of rivals to tape backups are on the market. However, if you can afford a high-quality DDS, DAT 72, or AIT tape drive, you can get a high-performance and high-reliability solution because these same drives are used in the demanding roles of network backup.

Advantages of Tape Backup Drives

Although tape backup drives are no longer the one-size-fits-all panacea for all types of bigger-than-floppy storage problems, they have their place in keeping your data safe. Following are several good reasons for using tape backup drives:

- *Tape backups are a true one-cartridge backup process for individual client PCs, standalone computers, or network servers when high-capacity tape drives and cartridges are used.* Anytime multiple tapes or disks must be used to make a backup, the chances of backup failure increase.
- *If you or your company has made previous backup tapes, you must keep a tape drive to access that data or perform a restore from it.* Tape backup drives are necessary if you need to restore from previously made backup tapes.
- *If you want an easy media rotation method for preserving multiple full-system backups, tape backup drives are a good choice.* In general, tape drives are used where high capacity and high reliability are paramount. They can be expensive initially but are extremely inexpensive when you factor in the low cost of the media over time.

Common Tape Backup Standards

Tape drives come in a variety of industry-standard as well as some proprietary formats. The following list details several of the available formats:

- *QIC, QIC-Wide, and Travan.* Travan is a development of the QIC and QIC-Wide family of low-cost, entry-level tape backup drives. Travan drives can handle data up to 40GB at 2:1 compression.
- *DAT (Digital Audio Tape).* This is a newer technology than QIC and its offshoots, and it uses Digital Data Storage (DDS) technology to store data up to 40GB at 2:1 compression (DDS-4) and up to 72GB in the latest DDS fifth-generation drives. DAT drives are often referred to as DDS drives for this reason.
- *AIT (Advanced Intelligent Tape).* This is one promising successor to DAT/DDS because it can handle higher capacities than DAT.
- *Exabyte's (formerly Ecrix) VXA-1 and VXA-2 drives.* VXA-1 offers a capacity of 66GB at 2:1 compression and a variety of high-speed SCSI and IEEE 1394 interface options. The VXA-1 format has been approved by the ECMA, an important international organization that establishes standards for information and communication systems. The improved VXA-2 drives have capacities up to 160GB (2:1 compression).

Other tape backup standards, such as DLT (Digital Linear Tape) and 8mm, are used primarily with larger network file servers and are beyond the scope of this book.

QIC and Its Variants (QIC-Wide and Travan)

The first 1/4" tape drive was introduced in 1972 by 3M, and it used a cartridge size of 6"x4"x5/8". This pioneering cartridge established the so-called "DC" data cartridge standard that was used with the first true QIC-standard drive, the 60MB QIC-02, introduced in 1983. The QIC-02 compatible drives were sold for several years and, like many early tape backup drives, used a dedicated host adapter board. QIC-02's small capacity began to be a problem in the mid-1980s, and many other QIC standards were created for larger drives.

The now-inactive Quarter-Inch Committee (<http://www.qic.org>) introduced more than 120 standards over the years in both the older DC and newer minicartridge (MC) forms. This huge number of standards has actually led to a fragmented marketplace that makes it increasingly difficult to determine the backward-compatibility and cross-compatibility factors that QIC, ironically, was established to provide. QIC-Wide technology, developed by Sony, is not an official QIC standard, but QIC-Wide drives can read and write some types of QIC minicartridge media.

This section focuses on the recent and current minicartridge versions of Travan, the latest development of the QIC and QIC-Wide standards.

Note

For more information on QIC and QIC-Wide standards, see [Chapter 12](#) of *Upgrading and Repairing PCs, 11th Edition*, and [Chapter 12](#) of *Upgrading and Repairing PCs, 12th Edition*, found in their entirety on the disc accompanying this book.

Travan Cartridge Tape

The successor to both QIC-MC and QIC-Wide drives was created in 1994 by 3M (now Imation). Travan drives maintain backward compatibility with various QIC standards and provide backup capabilities up to 20GB uncompressed and 40GB at 2: 1 compression.

The Travan platform features a unique drive/minicartridge interface patented by Imation. The Travan platform fits in a 3 1/2" form factor, enabling easy installation in a variety of systems and enclosures. Travan drives can accept current QIC, QIC-Wide, and Travan minicartridgesa critical need for users, given the installed base of more than 200 million QIC-compatible minicartridges worldwide.

Currently, several levels of Travan cartridges and drives are available, each based on a particular QIC standard. [Table 10.10](#) lists the standard Travan cartridges and capacities. All Travan cartridges use .315" (8mm) wide tape.

Table 10.10. Travan Family Cartridges and Capacities

Travan Cartridge (Previous Name)	Capacity/2:1 Compression	Read/Write Compatible with	Read Compatible with
Travan-1 (TR-1)	400MB/800MB	QIC-80, QW5122	QIC-40
Travan-3 (TR-3)	1.6GB/3.2GB	TR-2, QIC-3020, QIC-3010, QW-3020XLW, QW-3010XLW	QIC-80, QW-5122, TR-1
Travan 8GB (Travan 4/TR-4)	4GB/8GB	Travan 8, QIC-3080, QIC-Wide (3080)	QIC-80, QIC-3010, QIC-Wide (3010), QIC-3020, QIC-Wide (3020), TR-1, TR-3
Travan NS-8 ^[1]	4GB/8GB	TR-4, QIC-3080	QIC-Wide (3080)
Travan NS-20 (Travan TR-5)	10GB/20GB		Travan 8GB, QIC-3095

Travan 40GB
(Travan TR-7)

20GB/40GB

Travan NS-20

2. *This drive and cartridge also support Travan NS technology.*

^[1] *This cartridge can be used in place of the Travan 8GB (TR-4); the same cartridge can be used on either NS8 or TR-4 drives.*

Note

Backward compatibility can vary with drive; consult the manufacturer before purchasing any drive to verify backward compatibility issues.

Most Travan drives on the market today use the Network Series (NS) technology described in the following section.

The Travan NS

Drives that support Travan NS technology are designed to solve two problems that have plagued tape backup users for many years: data compression and data verification.

On QIC-40 and above, QIC-Wide, and standard Travan drives, data compression is performed by the backup software used by the drive. This could cause the following problems:

- Drives might have difficulty reading data if different backup software was used to make the backup and perform the restoration.
- The speed of the computer can have a major impact on how fast backups can be performed; a typical backup program (such as Iomega's Ditto Tools) offers three settings: no compression, compress to save time, and compress to save space, forcing the user to choose between maximum data storage and maximum speed.

On the same drives, backup software supports a verification step that compares the data written to the tape with the data on the drive. Unfortunately, this requires that the tape be rewound to the beginning of the current backup and be read to the end while the hard disk is also read. The result? A backup that took 45 minutes without verification would take more than 90 minutes with verification enabled. This inefficient write-rewind-reread process has discouraged many users from relying on this safer backup method. Also, errors caused by changes in the state of a Windows 9x computer (such as screensavers being enabled or swapfiles changing in size) during the time passage between backup and verify tend to create the erroneous notion that the backup isn't accurate.

Travan NS-compatible drives (including the Travan 40) use a dual-head design, shown in [Figure 10.14](#), that enables data to be verified as soon as it is written (read-while-write). They also feature hardware data compression, which allows a higher data capacity (up to 40GB at 2:1 compression). The result is faster and more reliable backups. The Travan NS20 and Travan 40 cartridges also use a different metal media formula for greater data density than older Travan drives do.

Figure 10.14. Travan NS and Travan 40 tape drives use separate read and write heads to enable data to be verified as soon as it is written, saving the time-consuming rewind and verify operation used with QIC, QIC-Wide, and earlier Travan drives.

Travan 20 and 40 drives are currently available from Quantum, thanks to Quantum's 2005 acquisition of Certance (formerly Seagate Removable Storage Solutions LLC). Travan 40GB drives are available in internal ATA/IDE and external USB 2.0 form factors. Travan 20 drives are available in internal ATA/IDE and SCSI-2 and external USB 2.0 form factors.

Quantum/Certance media and cleaning cartridge model numbers include the following:

- CTM40, for Travan 40 media
- CTM20, for Travan 20 media
- CTMCL, cleaning cartridge for Travan-8, NS-8, Travan, and Travan 40 drives

Media is also available from many other vendors, including Dell, IBM, Imation, Sony, and Seagate. [Figure 10.15](#) illustrates a typical Travan 20 or Travan 40 data cartridge. Before backing up to this type of media, you need to make sure the cartridge's write-protect switch is open (unlocked) for recording. When you've completed a backup, you should close the write-protect switch to prevent accidental overwriting on a cartridge that contains archival data.

Figure 10.15. Setting a Travan 20 or 40 cartridge's write-protect switch.

Orphaned Tape Backup Technologies

Although more tape backup standards are available than other types of removable-media drives, some once-common backup drives designed for PCs and small networks have become orphans. These include

- Proprietary versions of Travan Technology
- OnStream ADR and ADR

Proprietary Versions of Travan Technology

Ironically, because Travan technology was designed to bring an end to the QIC MC/QIC-Wide tape "wars," some now-discontinued drives used proprietary versions of the Travan standard. Nonstandard sizes include

- 5GB Tecmar/Iomega DittoMax
- 5GB HP/Colorado
- 6.6GB AIWA Bolt
- 7GB Tecmar/Iomega DittoMax
- 10GB Tecmar DittoMax

- 14GB HP/Colorado

Note

Iomega sold the Ditto and DittoMax backup product line to Tecmar, which went out of business in 2002. Although media is still available for these drives from Imation, they are orphans without technical support and should be replaced.

AIWA Computer Systems Division was shut down in October 1999. These are orphan drives that should be replaced.

The drive manufacturer is the principal supplier of media for some of these drives, whereas others are also supported with third-party media. Consult the drive manufacturers' websites for details.

OnStream ADR Drives

OnStream Data B.V. the successor to the original OnStream, Inc., spinoff from Philips Electronics declared bankruptcy in April 2003, making the OnStream ADR (introduced in 1999) and newer ADR tape backup product lines orphans. The remaining stock of OnStream drives, as well as some sizes of tape cartridges, drivers, manuals, and technical information, is available from Hastec B.V. (<http://www.hastec.nl>). For more information about OnStream ADR drives and tape cartridges, see *Upgrading and Repairing PCs, 15th Anniversary Edition*, contained in electronic form on the disc packaged with this book.

DAT/DDS, AIT, and Other High-Capacity Tape Drive Standards

Although Travan capacities have now reached 40GB compressed, users of today's high-capacity hard drives must turn to larger tape backup standards. The same tape backup standards long supported by workstation and large network servers can also be used with today's versions of Windows for both individual desktop computers and small network servers. Additionally, new high-capacity technologies are available to support today's larger drives.

4mm digital audio tape (DAT/DSS), 8mm videotape, 8mm AIT, digital linear tape, scalable linear recording (SLR), and Exabyte (originally Ecrix) VXA are the major choices available for users who need higher-capacity backups. An emerging choice for very high-capacity (100GB and up) drives is the Ultrium version of the LTO Technology standard. All these technologies are available in autoloading tape libraries suitable for large networks, as well as single-cartridge drives intended for small network servers or desktop use.

Proprietary Versus Open Standards

If you want a wider variety of choices in drives, media, and pricing, you might prefer to purchase a high-performance drive type that is made by several companies. However, some of the most advanced technologies are controlled by a single vendor.

Tape backup drive technologies available from multiple vendors include

- *DAT/DDS*. Introduced and licensed by Sony to numerous manufacturers. DAT 72, the fifth generation of DDS drives, is sold by HP and Quantum.

- *AIT*. Introduced and licensed by Sony to numerous manufacturers.
- *DLT*. Originally developed by Digital Equipment Corporation, but was purchased by Quantum in 1994. DLT and SuperDLT (SDLT) drives are also sold by ADIC, Hewlett-Packard, IBM, Overland Storage, and Tandberg Data.
- *LTO (Linear Tape-Open)*. LTO Ultrium drives are sold by Hewlett Packard, IBM, Quantum, and Tandberg Data.

The following drive technologies are sold by a single vendor:

- *SLR*. Tandberg Data
- *VXA*. Exabyte (originally developed by Ecrix)

However, third-party vendors might sell tape cartridges compatible with even so-called "proprietary" standards.

DAT/DDS Tape Drives

Of the many high-performance tape drives on the market, this author's longtime favorite has been the DAT/DDS tape drive family because of its combination of performance, capacity, reliability, and reasonable price. Five levels of DAT/DDS drive capacity have been developed:

- *DDS-1*. This entry-level member of the family (2GB native/4GB at 2:1 compression) is now obsolete.
- *DDS-2*. Has the same capacity as drives based on Travan NS8 (4GB native/8GB at 2:1 compression).
- *DDS-3*. Has a slightly larger capacity (12GB native/24GB at 2:1 compression) than Travan NS20.
- *DDS-4*. Has a 20GB native/40GB at 2:1 compression capacity, which is double the capacity of Travan NS20 and equal to Travan 40GB. It also works with DDS-3 media.
- *DAT72 (DDS Fifth Generation)*. The newest member of the DAT/DDS family, it has a 36GB native/72GB at 2:1 compression capacity. It also works with DDS-4 and DDS-3 media.

Even though DAT/DDS drives are more expensive than Travan drives with similar capacities, the media cost is much lower because of the drive's design. For example, you will pay about three times as much for a Travan NS20 cartridge as for a slightly higher-capacity DDS-3 cartridge. A DDS-4 cartridge, which offers double the capacity of Travan NS20, still sells for about 30% less. DDS drives are more reliable than Travan or earlier QIC-based drives, which is a vital consideration because the most important reason to use a tape backup is to perform a restore. The enhanced reliability of DDS drives is aided by the inclusion of automatic head-cleaning features built into most DDS drives and media.

After Sony announced in April 2001 that DDS-4 tape drives would be the end of the DAT/DDS lineup of drives, the future of DAT/DDS tapes was uncertain for awhile. However, in January 2003, HP and Certance announced the development of a fifth generation of DDS drives (DAT72), which features a higher capacity than DDS-4 and backward read/write compatibility with DDS-4 and DDS-3 tapes. The first DAT72 drives were introduced in July 2003. DAT72 nearly doubles the capacity of DDS-4.

Certance is now owned by Quantum. Quantum's DAT72 drives feature a combination of technologies called TapeShield that are designed to protect drives and data. TapeShield, previously available on Certance's DDS-4 drives, features

- A sealed chamber for the head-to-tape interface
- A continuous-contact capstan cleaner
- A sapphire media-cleaning blade that removes debris from the tape before it contaminates the drive

These improvements enable DAT72 drives to run 10 times longer in dusty conditions than similar drives lacking these features. DAT72 drives from Quantum also feature SmartShield, which uses multiple reads to improve data recovery when reading from out-of-spec or weak recorded tapes.

HP's DAT72 drives include One Button Disaster Recovery, an easy-to-use disaster-recovery feature designed to restore a system to its most recent backed-up condition.

Helical Scan Recording on DAT, 8mm, and AIT Drives

Exabyte 8mm, Sony DAT/DDS, and Sony AIT use helical scan recording. The read/write heads used in helical scan recording are mounted on a drum and write data at a slight angle to the tape, using a mechanism highly reminiscent of that in a VCR. The entire surface of the tape is used to store data, enabling more data to be placed in a given length of tape than with the linear recording techniques used by the QIC family of drives.

AIT Unique Features

Sony's AIT has several unique features designed to make backup and restoration faster and more reliable. An optional Memory In Cassette (MIC) chip allows the cartridge to remember which of the 256 on-tape partitions were used for the data you want to restore, so the correct starting point can be located in seconds. AIT drives also have a servo tracking system called Auto Tracking Following (ATF), which is used for accurate data-track writing, and Advanced Lossless Data Compression (ALDC), a mainframe-style compression method that can compress data to a greater extent than other methods. The drives have several other features, including built-in head cleaning that is activated when soft (correctable) errors reach a preset limit, metal-evaporated tape media that avoids head contamination, and a 3 1/2" form factor.

DLT and SDLT Unique Features

DLT segments the tape into parallel horizontal tracks and records data by streaming the tape across a single stationary head at 100"150" per second during read/write operations. This is a dramatic contrast to traditional helical-scan technology, in which the data is recorded in diagonal stripes with a rotating drumhead while a much slower tape motor draws the media past the recording head.

The result is a very durable drive and a robust medium. DLT drive heads have a minimum life expectancy of 15,000 hours under worst-case temperature and humidity conditions, and the tapes have a life expectancy of 500,000 passes.

SDLT uses several technologies to increase capacity and reliability over those of the already-impressive DLT standards. These include laser-guided magnetic recording (LGMR), a pivoting optical servo on the backside of the media, thin-film magneto-resistive cluster heads for tape reading and writing, high-efficiency PRML channels for greater recording density, improved media coating, and a positive engagement tape-leading buckling mechanism.

SDLT drives can read SDLT and DLT media up to six generations back. This enables you to replace older, smaller drives with newer, larger drives without losing access to older backups.

SLR Unique Features

Tandberg's SLR drives use a linear recording method; the tape used by the SLR 40, SLR 60, SLR 75, SLR 100, and SLR 140 is divided into 192 tracks. Twenty-four prewritten servo tracks are used to adjust the

position of the read/write head as necessary. This feature is designed to ensure compatibility of SLR tapes between drives, enabling a tape written by one drive unit to be readable by another unit. Four tracks are written at the same time in parallel. The entry-level SLR 7 uses a simplified recording method that uses 72 tracks, writing 2 tracks at a time in parallel. Both tape types have fault-tolerance features that enable the drive to switch to another track for data recording if the original track fails. SLR media is available from most major tape vendors.

Exabyte VXA Unique Features

The Exabyte VXA drives (originally developed by Ecrix, which merged with Exabyte in November 2001) combine special recording and playback methods. The recording method used somewhat resembles a normal helical scan, but the tape is guided past the magnetic drum with a completely different type of mechanism and the data is recorded at variable speeds that change according to how fast the host can transmit data. This eliminates the need to wind tape backward because of data underruns (back-hitching). Data is recorded in 64-byte groups of 387 data packets rather than in linear blocks. VXA drives use a special read feature called overscan operation (OSO). OSO performs redundant reads of each group of data packets, enabling data to be retrievable even from damaged tapes. The packetizing of data works the same way as on the Internet: Data can be read in any order and reassembled into its original form when all packets are received. In tests, Exabyte and Ecrix have boiled, frozen, and even poured hot coffee over VXA tapes and been able to retrieve 100% of the stored data.

LTO Ultrium Technology Unique Features

Linear Tape-Open (LTO) is a very high-performance tape backup technology. Although there were originally two versions of LTO (high-capacity Ultrium and high-speed Accelis), only Ultrium-based drives have been produced.

LTO Ultrium drives have been produced in three generations:

- LTO-1 supports 200GB (2:1 compression)
- LTO-2 supports 400GB (2:1 compression)
- LTO-3 supports 800GB (2:1 compression)

Transfer rates range from 30MBps to 160MBps, depending on drive generation and manufacturer (larger-capacity drives are faster). LTO Ultrium drives have special features such as dynamic power-down (which protects tapes from damage during a power interruption), intelligent data compression, intelligent media analysis to avoid suspect tape areas, and variable tape speed to minimize back-hitching (moving the tape backward because of a data underrun).

Comparing Tape Backup Technologies

As the preceding sections indicate, you have many choices in large, high-performance tape backup. All the drive technologies discussed in this section use various SCSI interface versions and can be purchased as internal or external drives; some are also available with USB 2.0 or IEEE 1394a interfaces. Even though they are more expensive than Travan drives, they offer the capacities needed by today's larger hard drives.

Unlike the confusing backward-compatibility picture for QIC-family drives, the more advanced drives in each family are generally backward compatible with smaller drives.

[Table 10.11](#) summarizes the performance and capacities of these tape technologies and compares them to

Travan NS20 and 40GB drives. The media cost per MB assumes 2:1 compression and is based on typical prices for media at major online vendors.

Table 10.11. High-Performance Tape Backup Standards Compared

Drive Type	Capacity/2:1 Compressed	Backup Speed (Native/Compressed)	Media Cost per GB
Travan NS20	10GB/20GB	1MBps2MBps	\$2.50
DAT DDS-3	12GB/24GB	1.1MBps2.2MBps	\$0.25
Travan 40GB	20GB/40GB	2MBps4MBps ATA; 1MBps2MBps USB 2	\$1.38
DAT DDS-4	20GB/40GB	2MBps4.8MBps	\$0.28
SLR 7	20GB/40GB	3MBps6MBps	\$1.60
DLT 4000	20GB/40GB	1.5MBps3MBps	\$1.10
SLR 50	25GB/50GB	2MBps4MBps	\$2.38
SLR 60	30GB/60GB	2MBps4MBps	\$1.12
VXA-1	33GB/66GB	3MBps6MBps	\$1.21
AIT-1	35GB/70GB	3MBps6MBps	\$0.86
DAT72	36GB/72GB	3.5MBps7MBps	\$0.28
DLT 8000	40GB/80GB	3MBps6MBps	\$0.50
SLR 100	50GB/100GB	5MBps10MBps	\$0.94
AIT-2	50GB/100GB	6MBps12MBps	\$0.58
VXA-2	80GB/160GB	6MBps12MBps	\$0.58

From [Table 10.11](#), you can see that the lowest media cost is available with DDS and DAT72 drives. However, some other drive technologies offer faster performance, albeit at higher costs. For an individual computer or small network server, the DAT72 offers the best balance of initial cost, performance, and media cost per gigabyte.

Note

To learn more about DAT, DLT, and Exabyte 8mm tape drives, see *Upgrading and Repairing PCs, 11th Edition*, which is included in printable PDF format on the disc accompanying this book.

To learn more about DAT72, SDLT, and LTO Ultrium drives and tape libraries, including installation and configuration, see my new book *Upgrading and Repairing Servers* (Que, 2006).

Choosing a Tape Backup Drive

Choosing a tape backup drive can be a simple job if you need to back up a single standalone system with a relatively small hard drive. The decision becomes more complex if the system has a larger hard drive or if you must back up a desktop system as well as a laptop. Choosing a tape backup drive type can be an even more complex program if you must back up a network server's hard drives and perhaps even back up the workstations from the server. As you ponder which backup tape drive you should select, consider the following factors:

- The amount of data you must back up
- The interfaces your equipment supports
- The data throughput you need
- The tape standard that is best for your needs
- The cost of the drive and tapes
- The capabilities and compatibility of the included driver and backup software
- Support for disaster recovery

By balancing the considerations of price, capacity, throughput, compatibility, and tape standard, you can find a tape drive that best meets your needs.

Note

When purchasing a tape backup drive, take the time to look through magazines in which dealers or distributors advertise. Several publications specialize in PCs and carry advertising from many hardware and software distributors. I recommend publications such as *Computer Reseller News* and *Computer Shopper*. CNet's online shopping service (<http://shopper.cnet.com>) can help you locate multiple sources for both popular and rare items quickly.

These publications cater to people or companies willing to go around the middlemen and buy direct. By reading such publications, you can get an excellent idea of the drives available and the price you can expect to pay.

While reading about drive capabilities and prices, don't neglect to read reviews of the software included with each drive. Verify that the software capabilities match your expectations and needs. This is especially important if you intend to use the drive on a nonWindows system because most backup software today is tailored for Windows. If you are not satisfied with the backup software included with a backup drive, check with the vendor to see whether a bare drive (no software) is available; then check with your preferred backup software vendor to verify that the drive you prefer is supported.

Capacity

The first rule for selecting a tape backup drive is to buy a drive with a capacity large enough for your needs, both now and for the foreseeable future. The ideal is to buy a drive with enough capacity so you can start your backup software, insert a blank tape in the drive, walk away from the system, and find the backup completed when you return. Because tape backups are generally rated by their maximum (2:1

compression) capacities which is seldom reached in practice you should calculate the "true" size of a tape backup drive by multiplying the native (noncompressed) capacity of a drive by 1.5 (equal to rating the drive as 1.5:1 compression). Thus, a so-called "20GB" tape backup might be better described as having a "15GB" capacity (10GB uncompressed times 1.5). Of course, the compressed capacity of a drive depends on the backup software you use, the settings you use, and the type of data you back up. Already compressed data, such as Zip archives, JPEG and GIF, and some types of TIFF graphics files, can't be compressed further, whereas text and database files can be compressed significantly. If you find that you have higher or lower compression ratios during backup, use the compression ratio you normally achieve to help estimate your true backup capacity.

You should always ensure that your tape backup medium supports a capacity larger than your largest single drive or partition. This makes automated backups possible because you won't have to change a tape in the middle of a backup. And, even if you don't mind replacing tapes in the middle of a backup, a single-tape backup is safer. If the first tape of a multiple-tape backup is damaged or lost, the entire backup is unusable with most backup systems!

Tape Standards and Compatibility

The next most important consideration, after adequate capacity, is choosing a drive whose tapes meet a standard that is useful to you. If you have existing tapes you want to restore, or you receive tapes from other users that you must read, you need a drive that can work with those tapes. Use the backward compatibility information listed earlier to help you decide on a drive to purchase if this feature is important to you.

If your ability to work with older tape media is only an occasional issue, you might prefer to buy a high-performance drive for current backups and maintain an older drive that matches the older standard.

Software Compatibility

Equally important to your consideration is the software required to operate each drive. Currently, most ATA drives come with software that runs under Windows operating system versions from 98 to XP. SCSI tape drives usually also support Windows NT, Windows 2000/XP, Linux, or various versions of UNIX. USB-based drives are primarily designed for Windows 98/Me/2000/XP. Check the manufacturers' websites for operating system compliance if your office's computers use more than one operating system.

Most operating systems have their own software for backing up data to a tape drive. If you intend to use this software, you should verify that the drive you purchase is supported by each piece of software on each system you intend to use with the drive. Third-party programs usually offer more features, but you might need to buy separate programs for the various operating systems your office uses.

Data Throughput

Any of the ATA, IEEE 1394a, Hi-Speed USB, or SCSI interface drives covered earlier should provide adequate performance (1MBps or above when backing up compressed data), but performance suffers if you opt for the convenience of USB 1.1 drives.

Cost

You can figure the cost per GB for a drive in two ways: media cost only (which is valid for users with an existing drive; refer to [Table 10.11](#)) or drive plus media costs (which is a better method for new

purchasers). Regardless of your favorite choice(s) in removable storage, be sure to look at the total picture, taking into account the savings from multipack data and the benefits of the extra speed of SCSI and ATA.

Tip

One point worth remembering when you evaluate whether to buy a tape drive is that the cost of the tapes and drive, taken as a whole, is nowhere near as high as the costs (in terms of frustration and lost productivity) of a single data-damaging hard drive problem. Considering that most people are more likely to back up a system if they have a tape drive installed than if they must use another medium for the backup, the cost of a drive and tapes is quite small, even on a standalone PC used mostly for fun.

Support for Disaster Recovery

Disaster recovery, which enables you to create a tape backup and floppy disk set that can be used to reinstall an entire operating system and data file set without installing Windows first, is a function of both the backup software and the drive interface. Disaster recovery is supported with most backup programs.

Tape Drive Installation

Because most tape drives today use the same ATA, SCSI, USB, or parallel-port connection options that are used by other types of storage devices, you should see the appropriate sections of this book for more details about these devices:

- [Chapter 12](#) provides detailed instructions for installing hard drives, floppy drives, and CD drives.
- [Chapter 7](#) provides exhaustive coverage of the ATA interface.
- [Chapter 15](#) provides information on USB and IEEE-1394 interfaces.

Note

For more details about installing the older floppy-interface tape backup drives, see *Upgrading and Repairing PCs, 11th Edition*, available in printable PDF format on the disc included with this book.

For information on installing SCSI interface tape backup drives, see the Technical Reference section on the DVD included with this book

Tape Drive Backup Software

The most important decision you can make after you choose the tape standard and capacity of your backup tape drive is the backup software you will use with it.

The three sources for tape backup software are

- Software bundled with the drive
- Software bundled with the operating system
- Software obtainable from third parties

Use the following checklist to evaluate the software you plan to use with your tape backup drive:

- *Device support.* You might prefer to use tape for most backups, but can you change your mind and use high-capacity removable magnetic or optical storage if you need to? Some backup software bundled with a particular drive will work only with that drive; check whether a full version with more options is available.
- *Compatibility with existing backups.* If you have replaced an older tape drive with a new one, can the backup software as well as the tape drive read your old data?
- *Adjustable compression options.* If you are using a drive without hardware data compression, you should be able to adjust the compression methods used, or even turn them off to make sending the tape to the user of another drive easier.
- *Data safety options.* In addition to verification, good tape software should also include some form of ECC error correction to make recovering the data in case of media damage easier.
- *Disaster recovery.* Many bundled or operating-system-standard backup programs require you to reinstall the operating system before you can restore the contents of a crashed drive. Insist on a disaster recovery feature that will allow you to restore a drive from bootable disks and the tape backup without taking the time to reinstall the operating system first. Keep in mind that you need to verify that the tape drive and interface support disaster recovery. If you want to use a USB or an IEEE 1394a drive for disaster recovery, you usually need to make a boot disk or CD with disaster-recovery software that supports these interfaces. Some backup programs support only SCSI or ATAPI drives for disaster recovery.

Other useful features to look for include

- *Unattended backup scheduling.* Enables you to schedule a backup for a time when you won't need to use your computer. You might be able to use the scheduling features in Windows if the software itself lacks this option.
- *Macro capability.* Use when selecting options and the files to back up.
- *A quick tape-erase capability.* Use when erasing the entire contents of a tape.
- *Partial tape-erase capability.* Use when erasing only part of a tape.
- *Tape unerase capability.* Use when recovering erased data.
- *Password-protect capability.* Enables you to protect backup data from access by unauthorized persons.

Read reviews, check compatibility, look for trial versions, and be sure to test the backup and restore features as you look for the best tape backup program for your needs.

Tip

Backup software vendor Novastor (www.novastor.com) has a unique solution for a major problem caused by moving from an older backup system to a new one: What to do with the data on the older tapes? Its TapeCopy 2.1 software enables you to move data archives from your outmoded SCSI, ATA/IDE, USB, or FireWire tape backup to a new backup system. You can also use it to make hard disk copies of your tapes and to duplicate a backup tape on a similar drive. If you have extensive backup data and don't want to retain your old tape backup drive, TapeCopy v2.1 might be the answer. See the website for specific model compatibility and to download a trial version.

Backup and Restoration Troubleshooting

If you are having problems with backing up or restoring data, you need to first identify your problem from the following sections and then follow the steps for the solutions they provide.

Backup Drive Not Recognized

- For USB drives, be sure you're using Windows 98 or higher and that the USB port is enabled in the BIOS; many systems originally shipped with Windows 95 have this port disabled. Check the USB port by connecting another device (such as a flash memory card reader or a webcam) to the port.
- For ATA drives, ensure that the master/slave jumpers on both drives are set properly.
- For SCSI drives, check termination and Device ID numbers.
- For external drives of any type, ensure that the drive is turned on a few seconds before starting the system. If not, you might be able to use the Windows Device Manager to refresh the list of devices, but if this doesn't work, you must restart the computer.

Backup or Restore Operation Failure

If your tape drive suffers a backup or restore operation failure, follow these steps:

1. Make sure you are using the correct type of tape cartridge.
2. Remove and replace the cartridge.
3. Restart the system.
4. Retension the tape.
5. Try a new tape.
6. Clean the tape heads.
7. Make sure all cables are securely connected.
8. Rerun the confidence test that checks data transfer speed with a blank tape. (This test overwrites any data that is already on the tape.)

Tape Retensioning

The solutions for many problems with tape-based backup devices involve retensioning one or more of the drive tapes. *Retensioning* a tape is the process of fast-forwarding and then rewinding the tape to ensure that there is even tension on the tape and rollers throughout the entire tape travel. Retensioning is recommended as a preventive maintenance operation when using a new tape or after an existing tape has been exposed to temperature changes or shock (for example, dropping the tape). Retensioning restores the proper tension to the media and removes unwanted tight spots that can develop.

The following are some general rules for retensioning:

- Retension any tapes that have not been used for more than a month or two.
- Retension tapes if you have errors reading them.
- Retension any tapes that have been dropped.
- In some cases, you might need to perform a retension operation several times to achieve the proper effect. Most tape drive or backup software includes a retension feature as a menu selection.

Bad Block or Other Types of Media Errors

To troubleshoot bad block or other types of media errors, follow these steps:

1. Retension the tape.
2. Clean the heads.
3. Try a new tape.
4. Restart the system.
5. Try initializing the tape.
6. Perform a secure erase on the tape. (Previous data will no longer be retrievable from the tape.)

System Lockup or Freeze While Running Tape Backup

If your system locks up or freezes while running a tape backup, follow these steps:

1. Ensure that your system meets at least the minimum requirements for both the tape drive and the backup software.

2. For ATA/IDE (ATAPI) tape drives, make sure the tape drive is using a different host adapter than the hard disk. Set the CD or DVD drive to master and the tape drive to slave if both are using the same ATA/IDE port.
3. For SCSI tape drives, check device IDs, particularly if a new SCSI device has been installed since the last time the tape drive was used. Note that most vendors recommend that the tape drive be on a separate bus from the system's SCSI hard disk or SCSI RAID array.
4. Check the BIOS boot sequence; ensure that it is not set to ATAPI (tape/CD-ROM) devices if the tape drive is configured as a master device or as a slave with no master.
5. Make sure the hard drive has sufficient free space; most backup programs temporarily use hard drive space as a buffer for data transfer.
6. Hard drive problems can cause the backup software to lock up. Check your hard disk for errors by using CHKDSK or a comparable utility.
7. Check for viruses.
8. Check for previous tape drive installations; ensure that any drivers from previous installations are removed.
9. Restart the server in VGA mode. If the problem does not recur, contact your graphics board manufacturer for an updated video driver.
10. Disable antivirus programs and Advanced Power Management.
11. Try the tape drive on another computer system and different operating system, or try swapping the drive, card, and cable with known-good, working equipment. Start by swapping the cables.

Other Tape Drive Problems

The following are some other issues that might cause problems in general with tape backups:

- Corrupted data or ID information on the tape.
- Incorrect BIOS (CMOS) settings.
- Networking problems (outdated network drivers and so on).
- A tape that was recorded by another tape drive. If the other drive can still read the tape, this might indicate a head-alignment problem or an incompatible environment.
- Slow performance. If you use a USB 2.0 (Hi-Speed USB) tape backup, be sure the USB ports on the system are configured to run in USB 2.0 mode and that your operating system has the appropriate drivers installed. If you use an ATAPI (ATA/IDE) tape backup, it should be connected to a host adapter different from the one the hard disk uses.

If you use a third-party backup program with disaster recovery enabled, be sure the boot floppies or boot CD-ROM are clearly labeled with the date and system name. If possible, store them with the media used to create the disaster recovery backup.

If you use the Windows XP Professional automated system recovery (ASR) feature, make sure the date and system name are marked clearly on the ASR floppy. If possible, store the floppy with the media used to create the ASR backup. Note that you must also use the Windows XP Professional distribution disc during

the ASR restore.

Backup Software Patches and Updates

Be sure to visit your backup software vendor's website to find the latest patches and updates for your backup software. If you use the backup software that is integrated in the operating system, visit your operating system vendor's website for updates.

Chapter 11. Optical Storage

[Troubleshooting Optical Drives](#)

Optical Technology

There are basically two types of disk storage for computers: magnetic and optical. *Magnetic* storage is represented by the standard floppy and hard disks installed in most PC systems, where the data is recorded magnetically on rotating disks. *Optical* disc storage is similar to magnetic disk storage in basic operation, but it reads and records using light (optically) instead of magnetism. Although most magnetic disk storage is fully read- and write-capable many times over, many optical storage media are either read-only or write-once. Note the convention in which we refer to magnetic as *disk* and optical as *disc*. This is not a law or rule but seems to be followed by most in the industry.

Some media combine magnetic and optical techniques, using either an optical guidance system (called a laser servo) to position a magnetic read/write head or a laser to heat the disk so it can be written magnetically, thus polarizing areas of the track, which can then be read by a lower-powered laser, as in magneto-optical (MO) drives. These technologies were covered in [Chapter 10](#), "Removable Storage."

At one time, it was thought that optical storage would replace magnetic as the primary online storage medium. However, optical storage has proven to be much slower and far less dense than magnetic storage and is much more adaptable to removable-media designs. As such, optical storage is more often used for backup or archival storage purposes and as a mechanism by which programs or data can be loaded onto magnetic drives. Magnetic storage, being significantly faster and capable of holding much more information than optical media in the same amount of space, is more suited for direct online storage and most likely won't be replaced in that role by optical storage anytime soon.

The most promising development in the optical area is that rewritable DVD drives are becoming so inexpensive that they're starting to replace compact disc-rewritable (CD-RW) drives, providing a truly high-capacity optical medium on which to distribute or back up data. Virtually all systems today have an optical drive of some type, and most have support for both DVD-ROM and CD-RW.

Optical technology standards for computers can be divided into two major types:

- CD (CD-ROM, CD-R, CD-RW)
- DVD (DVD-ROM, DVD-RAM, DVD-RW, DVD-R, DVD+RW, DVD+R)

Both CD and DVD storage devices are descended from popular entertainment standards; CD-based devices can also play music CDs, and DVD-based devices can play the same DVD videos you can purchase or rent. However, computer drives that can use these types of media also offer many additional features.

In the following sections, you will learn how CD and DVD drives and media are similar, how they differ from each other, and how they can be used to enhance your storage and playback options.

CD-Based Optical Technology

The first type of optical storage that became a widespread computing standard is the CD-ROM. CD-ROM, or *compact disc read-only memory*, is an optical read-only storage medium based on the original CD-DA (digital audio) format first developed for audio CDs. Other formats, such as CD-R (CD-recordable) and CD-RW (CD-rewritable), are expanding the compact disc's capabilities by making it writable. As you will see later in this chapter, technologies such as DVD (digital versatile disc) enable you to store more data than ever on the same size disc.

CD-ROM drives have been considered standard equipment on most PCs for many years. The primary exceptions to this rule are *thin clients* PCs intended for use only on networks and which normally lack drives of any type.

CD-ROM discs are capable of holding up to 74 or 80 minutes of high-fidelity audio (depending on the disc used). If used for data, the traditional 74-minute disc can hold up to 650MiB (or 682MB), whereas the newer 80-minute disc can hold up to 700MiB (or 737MB). A combination of music and data can be stored on one side (only the bottom is used) of a 120mm (4.72") diameter, 1.2mm (0.047") thick plastic disc.

CD-ROM has exactly the same form factor (physical shape and layout) of the familiar CD-DA audio compact disc and can, in fact, be inserted in a normal audio player. It usually isn't playable, though, because the player reads the subcode information for the track, which indicates that it is data and not audio. If it could be played, the result would be noise unless audio tracks precede the data on the CD-ROM (see the section "Blue Book CD EXTRA," later in this chapter). Accessing data from a CD-ROM using a computer is much faster than from a floppy disk but slower than a modern hard drive. The term *CD-ROM* refers to both the discs themselves and the drive that reads them.

Although only a few dozen CD-ROM discs, or titles, were published by 1988, currently hundreds of thousands of individual titles exist that contain data and programs ranging from worldwide agricultural statistics to preschool learning games. Individual businesses, local and federal government offices, and large corporations also publish thousands of their own limited-use titles. As one example, the storage space and expense that so many business offices once dedicated to the maintenance of a telephone book library can now be replaced by two discs containing the telephone listings for the entire United States.

CDs: A Brief History

In 1979, the Philips and Sony corporations joined forces to coproduce the CD-DA (Compact Disc-Digital Audio) standard. Philips had already developed commercial laserdisc players, and Sony had a decade of digital recording research under its belt. The two companies were poised for a battle the introduction of potentially incompatible audio laser disc formats when instead they came to terms on an agreement to formulate a single industry-standard digital audio technology.

Philips contributed most of the physical design, which was similar to the laserdisc format it had previously created with regards to using pits and lands on the disk that are read by a laser. Sony contributed the digital-to-analog circuitry, and especially the digital encoding and error-correction code designs.

In 1980, the companies announced the CD-DA standard, which has since been referred to as the Red Book

format (so named because the cover of the published document was red). The Red Book included the specifications for recording, sampling, and above all the 120mm (4.72") diameter physical format you live with today. This size was chosen, legend has it, because it could contain all of Beethoven's approximately 70-minute Ninth Symphony without interruption.

After the specification was set, both manufacturers were in a race to introduce the first commercially available CD audio drive. Because of its greater experience with digital electronics, Sony won that race and beat Philips to market by one month, when on October 1, 1982 Sony introduced the CDP-101 player and the world's first commercial CD recording Billy Joel's *52nd Street* album. The player was first introduced in Japan and then Europe; it wasn't available in the United States until early 1983. In 1984, Sony also introduced the first automobile and portable CD players.

Sony and Philips continued to collaborate on CD standards throughout the decade, and in 1983 they jointly released the Yellow Book CD-ROM standard. It turned the CD from a digital audio storage medium to one that could now store read-only data for use with a computer. The Yellow Book used the same physical format as audio CDs but modified the decoding electronics to allow data to be stored reliably. In fact, all subsequent CD standards (usually referred to by their colored book binders) have referred back to the original Red Book standard for the physical parameters of the disc. With the advent of the Yellow Book standard (CD-ROM), what originally was designed to hold a symphony could now be used to hold practically any type of information or software.

For more information on the other CD book formats, see the section "Compact Disc and Drive Formats" later in this chapter.

CD-ROM Construction and Technology

Although identical in appearance to CD-DAs, CD-ROMs store data instead of (or in addition to) audio. The CD-ROM drives in PCs that read the data discs are almost identical to audio CD players, with the main changes in the circuitry to provide additional error detection and correction. This is to ensure data is read without errors because what would be a minor if not unnoticeable glitch in a song would be unacceptable as missing data in a file.

A CD is made of a polycarbonate wafer, 120mm in diameter and 1.2mm thick, with a 15mm hole in the center. This wafer base is stamped or molded with a single physical track in a spiral configuration starting from the inside of the disc and spiraling outward. The track has a pitch, or spiral separation, of 1.6 microns (millionths of a meter, or thousandths of a millimeter). By comparison, an LP record has a physical track pitch of about 125 microns. When viewed from the reading side (the bottom), the disc rotates counterclockwise. If you examined the spiral track under a microscope, you would see that along the track are raised bumps, called *pits*, and flat areas between the pits, called *lands*. It seems strange to call a raised bump a *pit*, but that is because when the discs are pressed, the stamper works from the top side. So, from that perspective, the pits are actually depressions made in the plastic.

The laser used to read the disc would pass right through the clear plastic, so the stamped surface is coated with a reflective layer of metal (usually aluminum) to make it reflective. Then, the aluminum is coated with a thin protective layer of acrylic lacquer, and finally a label or printing is added.

Caution

CD-ROM media should be handled with the same care as a photographic negative. The CD-ROM is an optical device and degrades as its optical surface becomes dirty or scratched. Also it is important to note that, although discs are read from the bottom, the layer containing the

track is actually much closer to the top of the disc because the protective lacquer overcoat is only 67 microns thick. Writing on the top surface of a disc with a ballpoint pen, for example, will easily damage the recording underneath. You need to be careful even when using a marker to write on the disc. The inks and solvents used in some markers can damage the print and lacquer overcoat on the top of the disc, and subsequently the information layer right below. The important thing is to treat both sides of the disc carefully, especially the top (label) side.

Mass-Producing CD-ROMs

Commercial mass-produced CDs are stamped or pressed and not burned by a laser as many people believe (see [Figure 11.1](#)). Although a laser is used to etch data onto a glass master disc that has been coated with a photosensitive material, using a laser to directly burn discs would be impractical for the reproduction of hundreds or thousands of copies.

Figure 11.1. CD manufacturing process.

[\[View full size image\]](#)

The steps in manufacturing CDs are as follows (use [Figure 11.1](#) as a visual):

1. *Photoresist Coating.* A circular 240mm diameter piece of polished glass 6mm thick is spin-coated with a photoresist layer about 150 microns thick and then hardened by baking at 80°C (176°F) for 30 minutes.
2. *Laser Recording.* A Laser Beam Recorder (LBR) fires pulses of blue/violet laser light to expose and soften portions of the photoresist layer on the glass master.
3. *Master Development.* A sodium hydroxide solution is spun over the exposed glass master, which then dissolves the areas exposed to the laser, thus etching pits in the photoresist.
4. *Electroforming.* The developed master is then coated with a layer of nickel alloy through a process called *electroforming*. This creates a metal master called a *father*.
5. *Master Separation.* The metal master father is then separated from the glass master. The father is a metal master that can be used to stamp discs, and for short runs, it may in fact be used that way. However, because the glass master is damaged when the father is separated, and because a stamper can produce only a limited number of discs before it wears out, the father often is electroformed to create several reverse image *mothers*. These mothers are then subsequently electroformed to create the actual stampers. This enables many more discs to be stamped without ever having to go through the glass mastering process again.
6. *Disc Stamping Operation.* A metal stamper is used in an injection molding machine to press the data image (pits and lands) into approximately 18 grams of molten (350°C or 662°F) polycarbonate plastic with a force of about 20,000psi. Normally, one disc can be pressed every 23 seconds in a modern stamping machine.
7. *Metalization.* The clear stamped disc base is then sputter-coated with a thin (0.050.1 micron) layer of aluminum to make the surface reflective.
8. *Protective Coating.* The metalized disc is then spin-coated with a thin (67 micron) layer of acrylic lacquer, which is then cured with UV (ultraviolet) light. This protects the aluminum from oxidation.
9. *Finished Product.* Finally, a label is affixed or printing is screen-printed on the disc and cured with UV light.

This manufacturing process is identical for both data CD-ROMs and audio CDs.

Pits and Lands

Reading the information back from a disc is a matter of bouncing a low-powered laser beam off the reflective layer in the disc. The laser shines a focused beam on the underside of the disc, and a photosensitive receptor detects when the light is reflected back. When the light hits a land (flat spot) on the track, the light is reflected back; however, when the light hits a pit (raised bump), no light is reflected back.

As the disc rotates over the laser and receptor, the laser shines continuously while the receptor sees what is essentially a pattern of flashing light as the laser passes over pits and lands. Each time the laser passes

over the edge of a pit, the light seen by the receptor changes in state from being reflected to not reflected or vice versa. Each change in state of reflection caused by crossing the edge of a pit is translated into a 1 bit digitally. Microprocessors in the drive translate the light/dark and dark/light (pit edge) transitions into 1 bits, translate areas with no transitions into 0 bits, and then translate the bit patterns into actual data or sound.

The individual pits on a CD are 0.125 microns deep and 0.6 microns wide. Both the pits and lands vary in length from about 0.9 microns at their shortest to about 3.3 microns at their longest. The track is a spiral with 1.6 microns between adjacent turns (see [Figure 11.2](#)).

Figure 11.2. Pit, land, and track geometry on a CD.

The height of the pits above the land is especially critical as it relates to the wavelength of the laser light used when reading the disc. The pit (bump) height is exactly $1/4$ of the wavelength of the laser light used to read the disc. Therefore, the light striking a land travels $1/2$ of a wavelength of light farther than light striking the top of a pit ($1/4 + 1/4 = 1/2$). This means the light reflected from a pit is $1/2$ wavelength out of phase with the rest of the light being reflected from the disc. The out-of-phase waves cancel each other out, dramatically reducing the light that is reflected back and making the pit appear dark even though it is coated with the same reflective aluminum as the lands.

The read laser in a CD drive is a 780nm (nanometer) wavelength laser of about 1 milliwatt in power. The polycarbonate plastic used in the disc has a refractive index of 1.55, so light travels through the plastic 1.55 times more slowly than through the air around it. Because the frequency of the light passing through the plastic remains the same, this has the effect of shortening the wavelength inside the plastic by the same factor. Therefore, the 780nm light waves are now compressed to $780/1.55 = 500\text{nm}$. One quarter of 500nm is 125nm, which is 0.125 micron, the specified height of the pit.

Drive Mechanical Operation

A CD-ROM drive operates by using a laser to reflect light off the bottom of the disc. The reflected light is then read by a photo detector. The overall operation of a CD-ROM drive is as follows (see [Figure 11.3](#)):

Figure 11.3. Typical components inside a CD-ROM drive.

1.

The laser diode emits a low-energy infrared beam toward a reflecting mirror.

2.

The servo motor, on command from the microprocessor, positions the beam onto the correct track on the CD-ROM by moving the reflecting mirror.

3.

When the beam hits the disc, its refracted light is gathered and focused through the first lens beneath the platter, bounced off the mirror, and sent toward the beam splitter.

4.

The beam splitter directs the returning laser light toward another focusing lens.

5.

The last lens directs the light beam to a photo detector that converts the light into electric impulses.

6.

These incoming impulses are decoded by the microprocessor and sent along to the host computer as data.

When first introduced, CD-ROM drives were too expensive for widespread adoption. In addition, drive manufacturers were slow in adopting standards, causing a lag time for the production of CD-ROM titles. Without a wide base of software to drive the industry, acceptance was slow.

After the production costs of both drives and discs began to drop, however, CD-ROMs were rapidly assimilated into the PC world. This was particularly due to the ever-expanding size of PC applications. Virtually all software is now supplied on CD-ROM, even if the disc doesn't contain data representing a tenth of its potential capacity. In some cases, particularly large programs are now distributed on DVD as well as CD.

Tracks and Sectors

The pits are stamped into a single spiral track with a spacing of 1.6 microns between turns, corresponding to a track density of 625 turns per millimeter, or 15,875 turns per inch. This equates to a total of 22,188 turns for a typical 74-minute (650MiB) disc. The disc is divided into six main areas (discussed here and shown in [Figure 11.4](#)):

- *Hub clamping area*. The hub clamp area is just that: a part of the disc where the hub mechanism in the drive can grip the disc. No data or information is stored in that area.
- *Power calibration area (PCA)*. This is found only on writable (CD-R/RW) discs and is used only by recordable drives to determine the laser power necessary to perform an optimum burn. A single CD-R or CD-RW disc can be tested this way up to 99 times.
- *Program memory area (PMA)*. This is found only on writable (CD-R/RW) discs and is the area where the TOC (table of contents) is temporarily written until a recording session is closed. After the session is closed, the TOC information is written to the lead-in area.
- *Lead-in*. The lead-in area contains the disc (or session) TOC in the Q subcode channel. The TOC contains the start addresses and lengths of all tracks (songs or data), the total length of the program (data) area, and information about the individual recorded sessions. A single lead-in area exists on a disc recorded all at once (Disc At Once or DAO mode), or a lead-in area starts each session on a multisession disc. The lead-in takes up 4,500 sectors on the disc (1 minute if measured in time, or about 9.2MB worth of data). The lead-in also indicates whether the disc is multisession and what the next writable address on the disc is (if the disc isn't closed).
- *Program (data) area*. This area of the disc starts at a radius of 25mm from the center.
- *Lead-out*. The lead-out marks the end of the program (data) area or the end of the recording session on a multisession disc. No actual data is written in the lead-out; it is simply a marker. The first lead-out on a disc (or the only one if it is a single session or Disk At Once recording) is 6,750 sectors long (1.5 minutes if measured in time, or about 13.8MB worth of data). If the disc is a multisession disc, any subsequent lead-outs are 2,250 sectors long (0.5 minutes in time, or about 4.6MB worth of data).

The hub clamp, lead-in, program, and lead-out areas are found on all CDs, whereas only recordable CDs (such as CD-Rs and CD-RWs) have the additional power calibration area and program memory area at the start of the disc.

[Figure 11.4](#) shows these areas in actual relative scale as they appear on a disc.

Figure 11.4. Areas on a CD (side view).

[\[View full size image\]](#)

Officially, the spiral track of a standard CD-DA or CD-ROM disc starts with the lead-in area and ends at the finish of the lead-out area, which is 58.5mm from the center of the disc, or 1.5mm from the outer edge. This single spiral track is about 5.77 kilometers, or 3.59 miles, long. An interesting fact is that in a 56x CAV (constant angular velocity) drive, when reading the outer part of the track, the data moves at an actual speed of 162.8 miles per hour (262km/h) past the laser. What is more amazing is that even when the data is traveling at that speed, the laser pickup can accurately read bits (pit/land transitions) spaced as little as only 0.9 microns (or 35.4 millionths of an inch) apart!

[Table 11.1](#) shows some of the basic information about the two main CD capacities, which are 74- and 80-minute. The CD standard originally was created around the 74-minute disc; the 80-minute versions were added later and basically stretch the standard by tightening up the track spacing within the limitations of the original specification. A poorly performing or worn out drive can have trouble reading the 80-minute discs.

Table 11.1. CD-ROM Technical Parameters

Advertised CD length (minutes)	74	80
Advertised CD capacity (MiB)	650	700

1x read speed (m/sec)	1.3	1.3
Laser wavelength (nm)	780	780
Numerical aperture (lens)	0.45	0.45

Media refractive index	1.55	1.55

Track (turn) spacing (um)	1.6	1.48
Turns per mm	625	676
Turns per inch	15,875	17,162
Total track length (m)	5,772	6,240
Total track length (feet)	18,937	20,472
Total track length (miles)	3.59	3.88

Pit width (um)	0.6	0.6
Pit depth (um)	0.125	0.125
Min. nominal pit length (um)	0.90	0.90
Max. nominal pit length (um)	3.31	3.31

Lead-in inner radius (mm)	23	23
Data zone inner radius (mm)	25	25
Data zone outer radius (mm)	58	58
Lead-out outer radius (mm)	58.5	58.5
Data zone width (mm)	33	33
Total track area width (mm)	35.5	35.5

Max. rotating speed 1x CLV (rpm)	540	540
Min. rotating speed 1x CLV (rpm)	212	212
Track revolutions (data zone)	20,625	22,297
Track revolutions (total)	22,188	23,986
<i>B = Byte (8 bits)</i>		
<i>KB = Kilobyte (1,000 bytes)</i>		
<i>KiB = Kibibyte (1,024 bytes)</i>		
<i>MB = Megabyte (1,000,000 bytes)</i>		
<i>MiB = Mebibyte (1,048,576 bytes)</i>		
<i>m = Meters</i>		

mm = Millimeters (thousandths of a meter)

um = Micrometers = microns (millionths of a meter)

CLV = Constant linear velocity

rpm = Revolutions per minute

The spiral track is divided into sectors that are stored at the rate of 75 sectors per second. On a disc that can hold a total of 74 minutes of information, that results in a maximum of 333,000 sectors. Each sector is then divided into 98 individual frames of information. Each frame contains 33 bytes: 24 bytes are audio data, 1 byte contains subcode information, and 8 bytes are used for parity/ECC (error correction code) information. [Table 11.2](#) shows the sector, frame, and audio data calculations.

Table 11.2. CD-ROM Sector, Frame, and Audio Data Information

Advertised CD length (minutes)	74	80

Sectors/second	75	75
Frames/sector	98	98

Number of sectors	333,000	360,000
Sector length (mm)	17.33	17.33
Byte length (um)	5.36	5.36
Bit length (um)	0.67	0.67
Each Frame:		

Subcode bytes	1	1
Data bytes	24	24
Q+P parity bytes	8	8

Total bytes/frame	33	33
Audio Data:		

Audio sampling rate (Hz)	44,100	44,100

Samples per Hz (stereo)	2	2
Sample size (bytes)	2	2
Audio bytes per second	176,400	176,400
Sectors per second	75	75

Audio bytes per sector	2,352	2,352
Each Audio Sector (98 Frames):		

Q+P parity bytes	784	784
Subcode bytes	98	98
Audio data bytes	2,352	2,352

Bytes/sector RAW (unencoded)	3,234	3,234

Hz = Hertz (cycles per second)

mm = Millimeters (thousandths of a meter)

um = Micrometers = microns (millionths of a meter)

Sampling

When music is recorded on a CD, it is sampled at a rate of 44,100 times per second (Hz). Each music sample has a separate left and right channel (stereo) component, and each channel component is digitally converted into a 16-bit number. This allows for a resolution of 65,536 possible values, which represents the amplitude of the sound wave for that channel at that moment.

The sampling rate determines the range of audio frequencies that can be represented in the digital recording. The more samples of a wave that are taken per second, the closer the sampled result will be to the original. The Nyquist theorem (originally published by American physicist Harry Nyquist in 1928) states that the sampling rate must be at least twice the highest frequency present in the sample to reconstruct the original signal accurately. That explains why Philips and Sony intentionally chose the 44,100Hz sampling rate when developing the CDthat rate could be used to accurately reproduce sounds of up to 20,000Hz, which is the upper limit of human hearing.

So, you can see that audio sectors combine 98 frames of 33 bytes each, which results in a total of 3,234 bytes per sector, of which only 2,352 bytes are actual audio data. Besides the 98 subcode bytes per frame, the other 784 bytes are used for parity and error correction.

Subcodes

Subcode bytes enable the drive to find songs (which are confusingly also called *tracks*) along the spiral

track and also contain or convey additional information about the disc in general. The subcode bytes are stored as 1 byte per frame, which results in 98 subcode bytes for each sector. Two of these bytes are used as start block and end block markers, leaving 96 bytes of subcode information. These are then divided into eight 12-byte subcode blocks, each of which is assigned a letter designation PW. Each subcode channel can hold about 31.97MB of data across the disc, which is about 4% of the capacity of an audio disc. The interesting thing about the subcodes is that the data is woven continuously throughout the disc; in other words, subcode data is contained piecemeal in every sector on the disc.

The P and Q subcode blocks are used on all discs, and the RW subcodes are used only on CD+G (graphics) or CD TEXTtype discs.

The P subcode is used to identify the start of the tracks on the CD. The Q subcode contains a multitude of information, including

- *Whether the sector data is audio (CD-DA) or data (CD-ROM).* This prevents most players from trying to "play" CD-ROM data discs, which might damage speakers due to the resulting noise that would occur.
- *Whether the audio data is two or four channel.* Four channel is rarely if ever used.
- *Whether digital copying is permitted.* PC-based CD-R and RW drives ignore this; it was instituted to prevent copying to DAT (digital audio tape) or home audio CD-R/RW drives.
- *Whether the music is recorded with pre-emphasis.* This is a hiss or noise reduction technique.
- *The track (song) layout on the disc.*
- *The track (song) number.*
- *The minutes, seconds, and frame number from the start of the track (song).*
- *A countdown during an intertrack (intersong) pause.*
- *The minutes, seconds, and frames from the start of the first track (song).*
- *The barcode of the CD.*
- *The ISRC (International Standard Recording Code).* This is unique to each track (song) on the disc.

The R-W subcodes are used on CD+G (graphics) discs to contain graphics and text. This enables a limited amount of graphics and text to be displayed while the music is being played. These same subcodes are used on CD TEXT discs to store disc- and track-related information that is added to standard audio CDs for playback on compatible CD audio players. The CD TEXT information is stored as ASCII characters in the RW channels in the lead-in and program areas of a CD. On a CD TEXT disc, the lead-in area subcodes contain text information about the entire disc, such as the album, track (song) titles, and artist names. The program area subcodes, on the other hand, contain text information for the current track (song), including track title, composer, performers, and so on. The CD TEXT data is repeated throughout each track to reduce the delay in retrieving the data.

CD TEXTcompatible players typically have a text display to show this information, ranging from a simple one- or two-line, 20-character display such as on many newer RBDS (radio broadcast data system) automobile radio/CD players to up to 21 lines of 40-color, alphanumeric or graphics characters on home- or computer-based players. The specification also allows for future additional data, such as Joint Photographics Expert Group (JPEG) images. Interactive menus also can be used for the selection of text for display.

Handling Read Errors

Handling errors when reading a disc was a big part of the original Red Book CD standard. CDs use parity and interleaving techniques called *cross-interleave Reed-Solomon code (CIRC)* to minimize the effects of errors on the disk. This works at the frame level. When being stored, the 24 data bytes in each frame are first run through a Reed-Solomon encoder to produce a 4-byte parity code called "Q" parity, which then is added to the 24 data bytes. The resulting 28 bytes are then run through another encoder that uses a

different scheme to produce an additional 4-byte parity value called "P" parity. These are added to the 28 bytes from the previous encoding, resulting in 32 bytes (24 of the original data plus the Q and P parity bytes). An additional byte of subcode (tracking) information is then added, resulting in 33 bytes total for each frame. Note that the P and Q parity bytes are not related to the P and Q subcodes mentioned earlier.

To minimize the effects of a scratch or physical defect that would damage adjacent frames, several interleaves are added before the frames are actually written. Parts of 109 frames are cross-interleaved (stored in different frames and sectors) using delay lines. This scrambling decreases the likelihood of a scratch or defect affecting adjacent data because the data is actually written out of sequence.

With audio CDs and CD-ROMs, the CIRC scheme can correct errors up to 3,874 bits long (which would be 2.6mm in track length). In addition, for audio CDs, only the CIRC can also conceal (through interpolation) errors up to 13,282 bits long (8.9mm in track length). Interpolation is the process in which the data is estimated or averaged to restore what is missing. That would of course be unacceptable on a CD-ROM data disc, so this applies only to audio discs. The Red Book CD standard defines the *block error rate (BLER)* as the number of frames (98 per sector) per second that have any bad bits (averaged over 10 seconds) and requires that this be less than 220. This allows a maximum of up to about 3% of the frames to have errors, and yet the disc will still be functional.

An additional layer of error detection and correction circuitry is the key difference between audio CD players and CD-ROM drives. Audio CDs convert the digital information stored on the disc into analog signals for a stereo amplifier to process. In this scheme, some imprecision is acceptable because it would be virtually impossible to hear in the music. CD-ROMs, however, can't tolerate any imprecision. Each bit of data must be read accurately. For this reason, CD-ROM discs have a great deal of additional ECC information written to the disc along with the actual stored information. The ECC can detect and correct most minor errors, improving the reliability and precision to levels that are acceptable for data storage.

In the case of an audio CD, missing data can be interpolated—that is, the information follows a predictable pattern that enables the drive to guess the missing values. For example, if three values are stored on an audio disc, say 10, 13, and 20 appearing in a series, and the middle value is missing because of damage or dirt on the CD's surface you could interpolate a middle value of 15, which is midway between 10 and 20. Although this might not be exactly correct, in the case of audio recording, it probably won't be noticeable to the listener. If those same three values appear on a CD-ROM in an executable program, there is no way to guess at the correct value for the middle sample. Interpolation can't work because executable program instructions or data must be exact; otherwise, the program will crash or improperly read data needed for a calculation. Using the previous example with a CD-ROM running an executable program, guessing 15 is not merely slightly off—it is completely wrong.

In a CD-ROM on which data is stored instead of audio information, additional information is added to each sector to detect and correct errors as well as to identify the location of data sectors more accurately. To accomplish this, 304 bytes are taken from the 2,352 that originally were used for audio data and are instead used for sync (synchronizing bits), ID (identification bits), ECC, and EDC information. This leaves 2,048 bytes for actual user data in each sector. Just as when reading an audio CD, on a 1x (standard speed) CD-ROM, sectors are read at a constant speed of 75 per second. This results in a standard CD-ROM transfer rate of $2,048 \times 75 = 153,600$ bytes per second, which is expressed as either 153.6KBps or 150KiBps.

Note

Some of the copy protection schemes used on audio CDs intentionally interfere with the audio data and CIRC information in such a way as to make the disc appear to play correctly, but copies of the audio files or of the entire disc will be filled with noise. Copy protection for both audio and data CDs is discussed in more detail later in this chapter.

CD Capacity

Because a typical disc can hold a maximum of 74 minutes of data, and each second contains 75 blocks of 2,048 bytes each, you can calculate the absolute maximum storage capacity of a CD-ROM at 681,984,000 bytesrounded as 682MB (megabytes) or 650MiB (mebibytes). [Table 11.3](#) shows the structure and layout of each sector on a CD-ROM on which data is stored.

Table 11.3. CD-ROM Sector Information and Capacity

Each Data Sector (Mode 1):	74-Minute	80-Minute
Q+P parity bytes	784	784
Subcode bytes	98	98
Sync bytes	12	12
Header bytes	8	8
ECC/EDC bytes	284	284
Data bytes	2,048	2,048
Bytes/sector RAW (unencoded)	3,234	3,234
Actual CD-ROM Data Capacity:		
B	681,984,000	737,280,000
KiB	666,000	720,000
KB	681,984	737,280
MiB	650.39	703.13
MB	681.98	737.28
<i>B = Byte (8 bits)</i>		
<i>KB = Kilobyte (1,000 bytes)</i>		
<i>KiB = Kibibyte (1,024 bytes)</i>		

MB = Megabyte (1,000,000 bytes)

MiB = Mebibyte (1,048,576 bytes)

ECC = Error correction code

EDC = Error detection code

This information assumes the data is stored in Mode 1 format, which is used on virtually all data discs. You can learn more about the Mode 1/Mode 2 formats in the section on the Yellow Book and XA standards later in this chapter.

With data sectors, you can see that out of 3,234 actual bytes per sector, only 2,048 are actual CD-ROM user data. Most of the 1,186 other bytes are used for the intensive error detection and correction schemes to ensure error-free performance.

Data Encoding on the Disc

The final part of how data is actually written to the CD is very interesting. After all 98 frames are composed for a sector (whether audio or data), the information is then run through a final encoding process called EFM (eight to fourteen modulation). This scheme takes each byte (8 bits) and converts it into a 14-bit value for storage. The 14-bit conversion codes are designed so that there are never fewer than 2 or more than 10 adjacent 0 bits. This is a form of Run Length Limited (RLL) encoding called RLL 2,10 (RLL x, y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread, as well as to limit the minimum and maximum frequency of transitions actually placed on the recording media. With as few as 2 or as many as 10 0 bits separating 1 bits in the recording, the minimum distance between 1s is 3 bit time intervals (usually referred to as 3T) and the maximum spacing between 1s is 11 time intervals (11T).

Because some of the EFM codes start and end with a 1 or more than five 0s, three additional bits called *merge bits* are added between each 14-bit EFM value written to the disc. The merge bits usually are 0s but might contain a 1 if necessary to break a long string of adjacent 0s formed by the adjacent 14-bit EFM values. In addition to the now 17-bits created for each byte (EFM plus merge bits), a 24-bit sync word (plus 3 more merge bits) is added to the beginning of each frame. This results in a total of 588 bits (73.5 bytes) actually being stored on the disc for each frame. Multiply this for 98 frames per sector and you have 7,203 bytes actually being stored on the disc to represent each sector. A 74-minute disc, therefore, really has something like 2.4GB of actual data being written, which after being fully decoded and stripped of error correcting codes and other information, results in about 682MB (650MiB) of actual user data.

The calculations for EFM-encoded frames and sectors are shown in [Table 11.4](#).

Table 11.4. EFM-Encoded Data Calculations

EFM-Encoded Frames: 74-Minute 80-Minute		

Sync word bits	24	24

Subcode bits	14	14
Data bits	336	336
Q+P parity bits	112	112
Merge bits	102	102

EFM bits per frame	588	588
--------------------	-----	-----

EFM-Encoded Sectors:

EFM bits per sector	57,624	57,624
EFM bytes per sector	7,203	7,203

Total EFM data on disc (MB)	2,399	2,593
-----------------------------	-------	-------

B = Byte (8 bits)

KB = Kilobyte (1,000 bytes)

KiB = Kibibyte (1,024 bytes)

MB = Megabyte (1,000,000 bytes)

MiB = Mebibyte (1,048,576 bytes)

EFM = Eight to fourteen modulation

To put this into perspective, see [Table 11.5](#) for an example of how familiar data would actually be encoded when written to a CD. As an example, I'll use the letters "N" and "O" as they would be written on the disk.

Table 11.5. EFM Data Encoding on a CD

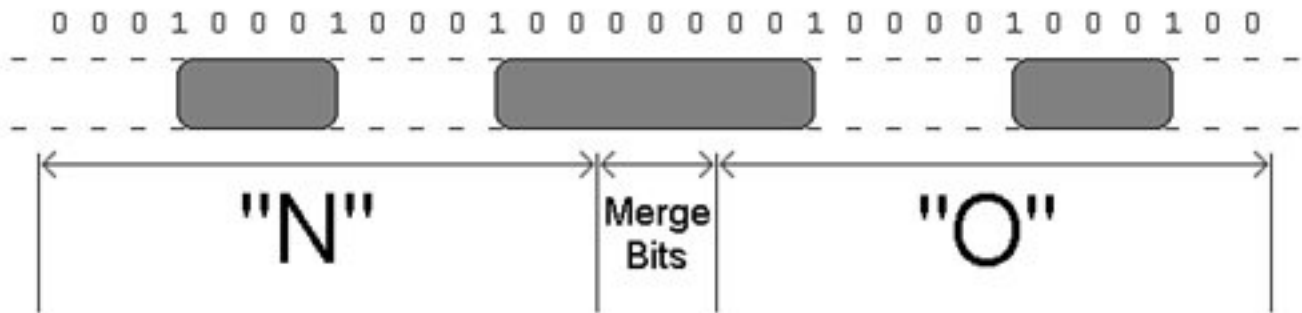

Character	"N"	"O"
ASCII decimal code	78	79
ASCII hexadecimal code	4E	4F
ASCII binary code	01001110	01001111
EFM code	00010001000100	00100001000100

ASCII = American Standard Code for Information Interchange

EFM = Eight to fourteen modulation

[Figure 11.5](#) shows how the encoded data would actually appear as pits and lands stamped into a CD.

Figure 11.5. EFM data physically represented as pits and lands on a CD.

The edges of the pits are translated into the binary 1 bits. As you can see, each 14-bit grouping is used to represent a byte of actual EFM encoded data on the disc, and each 14-bit EFM code is separated by three merge bits (all 0s in this example). The three pits produced by this example are 4T (4 transitions), 8T, and 4T long. The string of 1s and 0s on the top of the figure represent how the actual data would be read; note that a 1 is read wherever a pit-to-land transition occurs. It is interesting to note that this drawing is actually to scale, meaning the pits (raised bumps) would be about that long and wide relative to each other. If you could use a microscope to view the disc, this is what the word "NO" would look like as actually recorded.

Caring for Optical Media

Some people believe that optical discs and drives are indestructible when compared to their magnetic counterparts. Actually, modern optical drives are far less reliable than modern hard disk drives. Reliability is the bane of any removable media, and CD-ROMs and DVD-ROMs are no exceptions.

By far the most common causes of problems with optical discs and drives are scratches, dirt, and other contamination. Small scratches or fingerprints on the bottom of the disc should not affect performance because the laser focuses on a point inside the actual disc, but dirt or deep scratches can interfere with reading a disc.

To remedy this type of problem, you can clean the bottom surface of the CD with a soft cloth, but be careful not to scratch the surface in the process. The best technique is to wipe the disc in a radial fashion, using strokes that start from the center of the disc and emanate toward the outer edge. This way, any scratches will be perpendicular to the tracks rather than parallel to them, minimizing the interference they might cause. You can use any type of solution on the cloth to clean the disc, so long as it will not damage plastic. Most window cleaners are excellent at removing fingerprints and other dirt from the disc and don't damage the plastic surface.

If your disc has deep scratches, they can often be buffed or polished out. A commercial plastic cleaner such as that sold in auto parts stores for cleaning plastic instrument cluster and tail-lamp lenses is very good for removing these types of scratches. This type of plastic polish or cleaner has a very mild abrasive that polishes scratches out of a plastic surface. Products labeled as cleaners usually are designed for more

serious scratches, whereas those labeled as polishes are usually milder and work well as a final buff after using the cleaner. Polishes can be used alone if the surface is not scratched very deeply. The Skip Doctor device made by Digital Innovations (www.skipdoctor.com) can be used to make the polishing job easier.

Most people are careful about the bottom of the disc because that is where the laser reads, but the top is actually more fragile! This is because the lacquer coating on top of the disc is very thin, normally only 67 microns (0.240.28 thousandths of an inch). If you write on a disc with a ball point pen, for example, you will press through the lacquer layer and damage the reflective layer underneath, ruining the disc. Also, certain types of markers have solvents that can eat through the lacquer and damage the disc as well. You should write on discs only with felt tip pens that have compatible inks, such as the Sharpie or Staedtler Lumocolor brand, or other markers specifically sold for writing on CDs. In any case, remember that scratches or dents on the top of the disc are more fatal than those on the bottom. It's also important to keep in mind that many household chemicals (and even certain beverages), if spilled on an optical disc, can damage the coating and cause the material to crack or flake off. This, of course, renders the media useless.

Read errors can also occur when dust accumulates on the read lens of your CD-ROM drive. You can try to clean out the drive and lens with a blast of "canned air" or by using a drive cleaner (which can be purchased at most stores that sell audio CDs).

If your discs and your drive are clean, but you still can't read a particular disc, your trouble might be due to disc capacity. Many older CD-ROM drives are unreliable when they try to read the outermost tracks of newer discs where the last bits of data are stored. You're more likely to run into this problem with a CD that has a lot of data including some multimedia titles. If you have this problem, you might be able to solve it with a firmware or driver upgrade for your CD-ROM drive, but the only solution might be to replace the drive.

Sometimes too little data on the disc can be problematic as well. Some older CD-ROM drives use an arbitrary point on the disc's surface to calibrate their read mechanism, and if there happens to be no data at that point on the disc, the drive will have problems calibrating successfully. Fortunately, this problem usually can be corrected by a firmware or driver upgrade for your drive.

Many older drives have had problems working under Windows 9x. If you are having problems, contact your drive manufacturer to see whether a firmware or software-driver upgrade is available that might take care of your problem. With new high-speed drives available for well under \$100, it might not make sense to spend any time messing with an older drive that is having problems. It might be more cost-effective to upgrade to a new drive (which won't have these problems and will likely be much faster) instead.

If you have problems reading a particular brand or type of disk in some drives but not others, you might have a poor drive/media match. Use the media types and brands recommended by the drive vendor.

If you are having problems with only one particular disc and not the drive in general, you might find that your difficulties are in fact caused by a defective disc. See whether you can exchange the disc for another to determine whether that is indeed the cause.

DVD

DVD stands for digital versatile disc and in simplest terms is a high-capacity CD. In fact, every DVD-ROM drive *is* a CD-ROM drive; that is, they can read CDs as well as DVDs (many standalone DVD players can't read CD-R or CD-RW discs, however). DVD uses the same optical technology as CD, with the main difference being higher density. The DVD standard dramatically increases the storage capacity of, and therefore the useful applications for, CD-ROM-sized discs. A CD-ROM can hold a maximum of about 737MB (80-minute disc) of data, which might sound like a lot but is simply not enough for many up-and-coming applications, especially where the use of video is concerned. DVDs, on the other hand, can hold up to 4.7GB (single layer) or 8.5GB (dual layer) on a single side of the disc, which is more than 11 1/2 times greater than a CD. Double-sided DVDs can hold up to twice that amount, although you currently must manually flip the disc over to read the other side.

Up to two layers of information can be recorded to DVDs, with an initial storage capacity of 4.7GB of digital information on a single-sided, single-layer disc that is the same overall diameter and thickness of a current CD-ROM. With Moving Picture Experts Group standard 2 (MPEG-2) compression, that's enough to contain approximately 133 minutes of video, which is enough for a full-length, full-screen, full-motion feature film including three channels of CD-quality audio and four channels of subtitles. Using both layers, a single-sided disc could easily hold 240 minutes of video or more. This initial capacity is no coincidence; the creation of DVD was driven by the film industry, which has long sought a storage medium cheaper and more durable than videotape.

Note

It is important to know the difference between the DVD-Video and DVD-ROM standards. DVD-Video discs contain only video programs and are intended to be played in a DVD player connected to a television and possibly an audio system. DVD-ROM is a data storage medium intended for use by PCs and other types of computers. The distinction is similar to that between an audio CD and a CD-ROM. Computers might be capable of playing audio CDs as well as CD-ROMs, but dedicated audio CD players can't use a CD-ROM's data tracks. Likewise, computer DVD drives can play DVD-video discs (with MPEG-2 decoding in either hardware or software), but DVD video players can't access data on a DVD-ROM. This is the reason you must select the type of DVD you are trying to create when you make a writable or rewritable DVD.

The initial application for DVDs was as an upgrade for CDs as well as a replacement for prerecorded videotapes. DVDs can be rented or purchased like prerecorded VCR tapes, but they offer much higher resolution and quality with greater content. As with CDs, which initially were designed only for music, DVDs have since developed into a wider range of uses, including computer data storage and high-quality audio.

DVD History

DVD had a somewhat rocky start. During 1995, two competing standards for high-capacity CD-ROM drives were being developed to compete with each other for future market share. One standard, called Multimedia CD, was introduced and backed by Philips and Sony, whereas a competing standard, called the Super

Density (SD) disc, was introduced and backed by Toshiba, Time Warner, and several other companies. If both standards had hit the market as is, consumers as well as entertainment and software producers would have been in a quandary over which one to choose.

Fearing a repeat of the Beta/VHS situation that occurred in the videotape market, several organizations, including the Hollywood Video Disc Advisory Group and the Computer Industry Technical Working Group, banded together to form a consortium to develop and control the DVD standard. The consortium insisted on a single format for the industry and refused to endorse either competing proposal. With this incentive, both groups worked out an agreement on a single, new, high-capacity CD-type disc in September 1995. The new standard combined elements of both previously proposed standards and was called DVD, which originally stood for digital video disc, but has since been changed to digital versatile disc. The single DVD standard has avoided a confusing replay of the VHS versus Beta tape fiasco for movie fans and has given the software, hardware, and movie industries a single, unified standard to support.

After agreeing on copy protection and other items, the DVD-ROM and DVD-Video standards were officially announced in late 1996. Players, drives, and discs were announced in January 1997 at the Consumer Electronics Show (CES) in Las Vegas, and the players and discs became available in March 1997. The initial players were about \$1,000 each. Only 36 movies were released in the first wave, and they were available only in seven cities nationwide (Chicago, Dallas, Los Angeles, New York, San Francisco, Seattle, and Washington, D.C.) until August 1997 when the full release began. After a somewhat rocky start (much had to do with agreements on copy protection to get the movie companies to go along, and there was a lack of titles available in the beginning), DVD has become an incredible success. It will continue to grow as DVD moves from a read-only to a fully rewritable consumer as well as computer device.

The organization that controls the DVD video standard is called the DVD Forum and was founded by 10 companies, including Hitachi, Matsushita, Mitsubishi, Victor, Pioneer, Sony, Toshiba, Philips, Thomson, and Time Warner. Since its founding in April 1997, more than 230 companies have joined the forum. Because it is a public forum, anybody can join and attend the meetings; the site for the DVD forum is www.dvdforum.org. Because the DVD Forum was unable to agree on a universal recordable format, its members who are primarily responsible for CD and DVD technology (Philips, Sony, and others) split off to form the DVD+RW Alliance in June 2000; their site is www.dvdrw.com. They have since introduced the DVD+RW format, which is the fastest, most flexible and backward-compatible recordable DVD format. DVD+RW might someday replace the VCR at home, and it's already well on its way to replacing the CD-RW and floppy drives in your PC.

DVD Construction and Technology

DVD technology is similar to CD technology. Both use the same size (120mm diameter, 1.2mm thick, with a 15mm hole in the center) discs with pits and lands stamped in a polycarbonate base. Unlike a CD, though, DVDs can have two layers of recordings on a side and be double-sided as well. Each layer is separately stamped, and they are all bonded together to make the final 1.2mm-thick disc. The manufacturing process is largely the same, with the exception that each layer on each side is stamped from a separate piece of polycarbonate plastic and are then bonded together to form the completed disc. The main difference between CD and DVD is that DVD is a higher-density recording read by a laser with a shorter wavelength, focused more closely to the disc, which enables more information to be stored. Also, whereas CDs are single-sided and have only one layer of stamped pits and lands, DVDs can have up to two layers per side and can have information on both sides.

As with CDs, each layer is stamped or molded with a single physical track in a spiral configuration starting from the inside of the disc and spiraling outward. The disc rotates counterclockwise (as viewed from the bottom), and each spiral track contains pits (bumps) and lands (flat portions) just as on a CD. Each recorded layer is coated with a thin film of metal to reflect the laser light. The outer layer has a thinner

coating to allow the light to pass through to read the inner layer. If the disc is single-sided, a label can be placed on top; if it's double-sided, only a small ring near the center provides room for labeling.

Just as with a CD, reading the information back on a DVD is a matter of bouncing a low-powered laser beam off one of the reflective layers in the disc. The laser shines a focused beam on the underside of the disc, and a photosensitive receptor detects when the light is reflected back. When the light hits a land (flat spot) on the track, the light is reflected back; when the light hits a pit (raised bump), the phase differential between the projected and reflected light causes the waves to cancel and no light is reflected back.

The individual pits on a DVD are 0.105 microns deep and 0.4 microns wide. Both the pits and lands vary in length from about 0.4 microns at their shortest to about 1.9 microns at their longest (on single-layer discs).

Refer to the section "CD-ROM Construction and Technology," earlier in this chapter, for more information on how the pits and lands are read and converted into actual data, as well as how the drives physically and mechanically work.

DVD uses the same optical laser read pit and land storage that CDs do. The greater capacity is made possible by several factors, including the following:

- A 2.25 times smaller pit length (0.90.4 microns)
- A 2.16 times reduced track pitch (1.60.74 microns)
- A slightly larger data area on the disc (8,6058,759 square millimeters)
- About 1.06 times more efficient channel bit modulation
- About 1.32 times more efficient error correction code
- About 1.06 times less sector overhead (2,048/2,352,048/2,064 bytes)

The DVD disc's pits and lands are much smaller and closer together than those on a CD, allowing the same physical-sized platter to hold much more information. [Figure 11.6](#) shows how the grooved tracks with pits and lands are just over four times as dense on a DVD as compared to a CD.

Figure 11.6. DVD data markings (pits and lands) versus those of a standard CD.

DVD drives use a shorter wavelength laser to read these smaller pits and lands. A DVD can have nearly double the initial capacity by using two separate layers on one side of a disc and double it again by using both sides of the disc. The second data layer is written to a separate substrate below the first layer, which is then made semireflective to enable the laser to penetrate to the substrate beneath it. By focusing the laser on one of the two layers, the drive can read roughly twice the amount of data from the same surface area.

DVD Tracks and Sectors

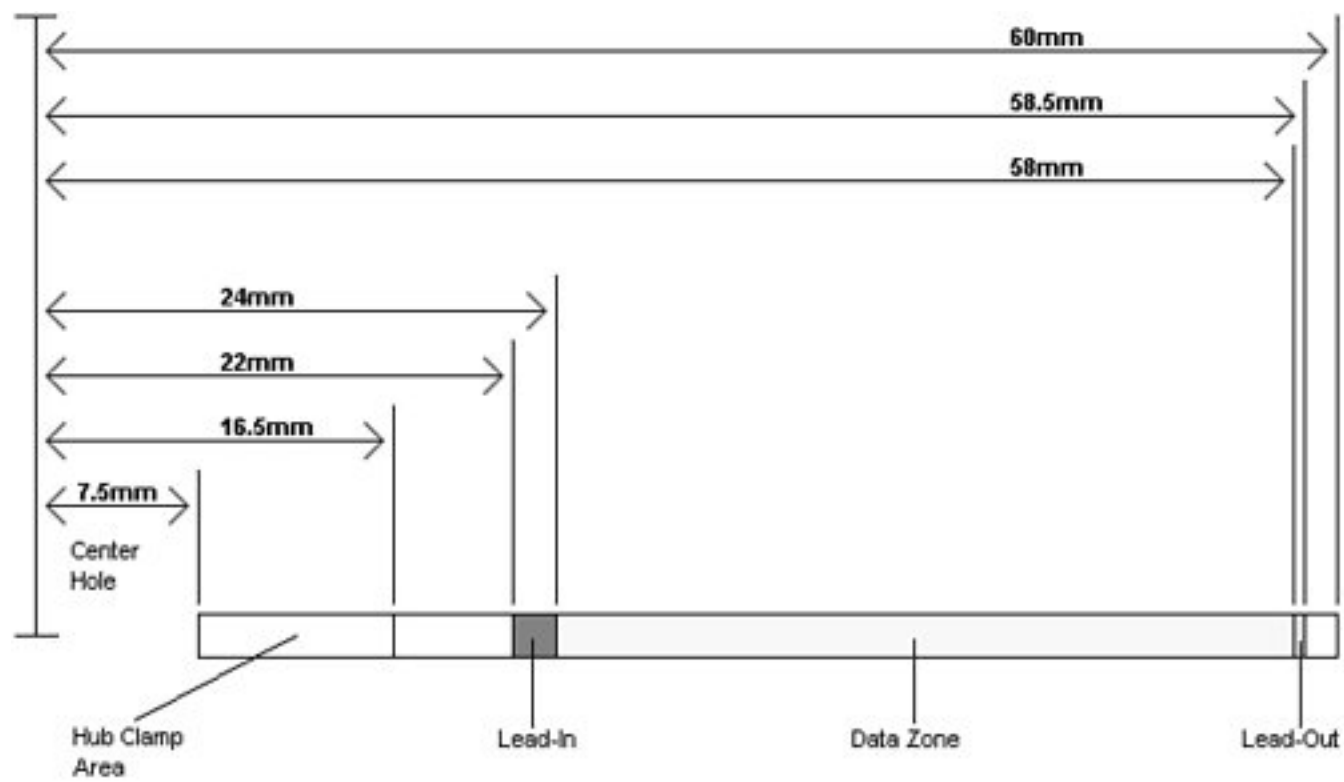

The pits are stamped into a single spiral track (per layer) with a spacing of 0.74 microns between turns, corresponding to a track density of 1,351 turns per millimeter or 34,324 turns per inch. This equates to a total of 49,324 turns and a total track length of 11.8km or 7.35 miles in length. The track is comprised of sectors, with each sector containing 2,048 bytes of data. The disc is divided into four main areas:

- *Hub clamping area.* The hub clamp area is just that, a part of the disc where the hub mechanism in the drive can grip the disc. No data or information is stored in that area.
- *Lead-in zone.* The lead-in zone contains buffer zones, reference code, and mainly a control data zone with information about the disc. The control data zone consists of 16 sectors of information repeated 192 times for a total of 3,072 sectors. Contained in the 16 (repeated) sectors is information about the disc, including disc category and version number, disc size and maximum transfer rate, disc structure, recording density, and data zone allocation. The entire lead-in zone takes up to 196,607 (2FFFFh) sectors on the disc. Unlike CDs, the basic structure of all sectors on a DVD are the same. The buffer zone sectors in the lead-in zone have all 00h (zero hex) recorded for data.
- *Data zone.* The data zone contains the video, audio, or other data on the disc and starts at sector number 196,608 (30000h). The total number of sectors in the data zone can be up to 2,292,897 per layer for single layer discs.
- *Lead-out (or middle) zone.* The lead-out zone marks the end of the data zone. The sectors in the lead-out zone all contain zero (00h) for data. This is called the middle zone if the disc is dual layer and is recorded in opposite track path (OPT) mode, in which the second layer starts from the outside of the disc and is read in the opposite direction from the first layer.

The center hole in a DVD is 15mm in diameter, so it has a radius of 7.5mm from the center of the disc. From the edge of the center hole to a point at a radius of 16.5mm is the hub clamp area. The lead-in zone starts at a radius of 22mm from the center of the disc. The data zone starts at a radius of 24mm from the center and is followed by the lead-out (or middle) zone at 58mm. The disc track officially ends at 58.5mm, which is followed by a 1.5mm blank area to the edge of the disc. [Figure 11.7](#) shows these zones in actual relative scale as they appear on a DVD.

Figure 11.7. Areas on a DVD (side view).

[\[View full size image\]](#)

Officially, the spiral track of a standard DVD starts with the lead-in zone and ends at the finish of the lead-out zone. This single spiral track is about 11.84 kilometers or 7.35 miles long. An interesting fact is that in a 20x CAV drive, when reading the outer part of the track, the data moves at an actual speed of 156 miles per hour (251km/h) past the laser. What is more amazing is that even when the data is traveling at that speed, the laser pickup can accurately read bits (pit/land transitions) spaced as little as only 0.4 microns or 15.75 millionths of an inch apart!

DVDs come in both single- and dual-layer as well as single- and double-sided versions. The double-sided discs are essentially the same as two single-sided discs glued together back to back, but subtle differences do exist between the single- and dual-layer discs. [Table 11.6](#) shows some of the basic information about DVD technology, including single- and dual-layer DVDs. The dual-layer versions are recorded with slightly longer pits, resulting in slightly less information being stored in each layer.

Table 11.6. DVD Technical Parameters

	DVD Type:		Single-Layer	Dual-Layer
<hr/>				
1x read speed (m/sec)			3.49	3.84
Laser wavelength (nm)			650	650
Numerical aperture (lens)			0.60	0.60
Media refractive index			1.55	1.55

<hr/>		
Track (turn) spacing (um)	0.74	0.74
Turns per mm	1,351	1,351
Turns per inch	34,324	34,324
Total track length (m)	11,836	11,836
Total track length (feet)	38,832	38,832
Total track length (miles)	7.35	7.35
<hr/>		
Media bit cell length (nm)	133.3	146.7
Media byte length (um)	1.07	1.17
Media sector length (mm)	5.16	5.68
Pit width (um)	0.40	0.40
Pit depth (um)	0.105	0.105
Min. nominal pit length (um)	0.40	0.44
Max. nominal pit length (um)	1.87	2.05
<hr/>		
Lead-in inner radius (mm)	22	22
Data zone inner radius (mm)	24	24
Data zone outer radius (mm)	58	58
Lead-out outer radius (mm)	58.5	58.5
Data zone width (mm)	34	34
Data zone area (mm ²)	8,759	8,759
Total track area width (mm)	36.5	36.5
<hr/>		
Max. rotating speed 1x CLV (rpm)	1,515	1,667
Min. rotating speed 1x CLV (rpm)	570	627
Track revolutions (data zone)	45,946	45,946
Track revolutions (total)	49,324	49,324
<hr/>		
Data zone sectors per layer per side	2,292,897	2,083,909
Sectors per second	676	676

Media data rate (mbits/sec)	26.15625	26.15625
Media bits per sector	38,688	38,688
Media bytes per sector	4,836	4,836
Interface data rate (mbits/sec)	11.08	11.08
Interface data bits per sector	16,384	16,384
Interface data bytes per sector	2,048	2,048

Track time per layer (minutes)	56.52	51.37
Track time per side (minutes)	56.52	102.74
MPEG-2 video per layer (minutes)	133	121
MPEG-2 video per side (minutes)	133	242

B = Byte (8 bits)

KB = Kilobyte (1,000 bytes)

KiB = Kibibyte (1,024 bytes)

MB = Megabyte (1,000,000 bytes)

MiB = Mebibyte (1,048,576 bytes)

GB = Gigabyte (1,000,000,000 bytes)

GiB = Gibibyte (1,073,741,824 bytes)

m = Meters

mm = Millimeters (thousandths of a meter)

mm² = Square millimeters

um = Micrometers = microns (millionths of a meter)

nm = Nanometers (billionths of a meter)

rpm = Revolutions per minute

ECC = Error correction code

EDC = Error detection code

CLV = Constant linear velocity

CAV = Constant angular velocity

As you can see from the information in [Table 11.6](#), the spiral track is divided into sectors that are stored at the rate of 676 sectors per second. Each sector contains 2,048 bytes of data.

When being written, the sectors are first formatted into data frames of 2,064 bytes: 2,048 are data, 4 bytes contain ID information, 2 bytes contain ID error detection (IED) codes, 6 bytes contain copyright information, and 4 bytes contain EDC for the frame.

The data frames then have ECC information added to convert them into ECC frames. Each ECC frame contains the 2,064-byte data frame plus 182 parity outer (PO) bytes and 120 parity inner (PI) bytes, for a total of 2,366 bytes for each ECC frame.

Finally, the ECC frames are converted into physical sectors on the disc. This is done by taking 91 bytes at a time from the ECC frame and converting them into recorded bits via 8 to 16 modulation. This is where each byte (8 bits) is converted into a special 16-bit value, which is selected from a table. These values are designed using an RLL 2,10 scheme, which is designed so that the encoded information never has a run of fewer than 2 or more than 10 0 bits in a row. After each group of 91 bytes is converted via the 8 to 16 modulation, 32 bits (4 bytes) of synchronization information is added. After the entire ECC frame is converted into a physical sector, 4,836 total bytes are stored.

[Table 11.7](#) shows the sector, frame, and audio data calculations.

Table 11.7. DVD Data Frame, ECC Frame, and Physical Sector Layout and Information

DVD Data Frame:

Identification data (ID) bytes	4
ID error detection code (IED) bytes	2
Copyright info (CI) bytes	6
Data bytes	2,048
Error detection code (EDC)	4

Data frame total bytes 2,064

DVD ECC Frame:

Data frame total bytes	2,064
Parity outer (PO) bytes	182
Parity inner (PI) bytes	120

ECC frame total bytes 2,366

DVD Media Physical Sectors:

ECC frame bytes	2,366
-----------------	-------

8 to 16 modulation bits	37,856
-------------------------	--------

Synchronization bits	832
----------------------	-----

Total encoded media bits/sector	38,688
---------------------------------	--------

Total encoded media bytes/sector	4,836
----------------------------------	-------

Original data bits/sector	16,384
---------------------------	--------

Original data bytes/sector	2,048
----------------------------	-------

Ratio of original to media data	2.36
---------------------------------	------

Unlike CDs, DVDs do not use subcodes and instead use the ID bytes in each data frame to store the sector number and information about the sectors.

Handling Errors

DVDs use more powerful error correcting codes than were first devised for CDs. Unlike CDs, which have different levels of error correction depending on whether audio/video or data is being stored, DVDs treat all information equally and apply the full error correction to all sectors.

The main error correcting in DVDs takes place in the ECC frame. Parity outer (column) and parity inner (row) bits are added to detect and correct errors. The scheme is simple and yet very effective. The information from the data frames is first broken up into 192 rows of 172 bytes each. Then, a polynomial equation is used to calculate and add 10 PI bytes to each row, making the rows now 182 bytes each. Finally, another polynomial equation is used to calculate 16 PO (Parity Outer) bytes for each column, resulting in 16 bytes (rows) being added to each column. What started out as 192 rows of 172 bytes becomes 208 rows of 182 bytes with the PI and PO information added.

The function of the PI and PO bytes can be explained with a simple example using simple parity. In this example, 2 bytes are stored (01001110 = N, 01001111 = O). To add the error correcting information, they are organized in rows, as shown in the following:

	Data bits
	1 2 3 4 5 6 7 8

Byte 1	0 1 0 0 1 1 1 0
--------	-----------------

Byte 2	0 1 0 0 1 1 1 1
--------	-----------------

Then, 1 PI bit is added for each row, using odd parity. This means you count up the 1 bits: In the first row there are 4, so the parity bit is created as a 1, making the sum an odd number. In the second row, the parity bit is a 0 because the sum of the 1s was already an odd number. The result is as follows:

	Data bits								
	1	2	3	4	5	6	7	8	PI
Byte 1	0	1	0	0	1	1	1	0	1
Byte 2	0	1	0	0	1	1	1	1	0

Next, the parity bits for each column are added and calculated the same as before. In other words, the parity bit will be such that the sum of the 1s in each column is an odd number. The result is as follows:

	Data bits								
	1	2	3	4	5	6	7	8	PI
Byte 1	0	1	0	0	1	1	1	0	1
Byte 2	0	1	0	0	1	1	1	1	0
P0	1	1	1	1	1	1	1	0	1

Now the code is complete, and the extra bits are stored along with the data. So, instead of just the 2 bytes being stored, 11 additional bits are stored for error correction. When the data is read back, the error correction bit calculations are repeated and they're checked to see whether they are the same as before. To see how it works, let's change one of the data bits (due to a read error) and recalculate the error correcting bits as follows:

	Data bits								
	1	2	3	4	5	6	7	8	PI
Byte 1	0	1	0	0	1	0	1	0	0
Byte 2	0	1	0	0	1	1	1	1	0
P0	1	1	1	1	1	0	1	0	1

Now, when you compare the PI and PO bits you calculated after reading the data to what was originally stored, you see a change in the PI bit for byte (row) 1 and in the PO bit for bit (column) 6. This identifies the precise row and column where the error was, which is at byte 1 (row 1), bit 6 (column 6). That bit was read as a 0, and you now know it is wrong, so it must have been a 1. The error correction circuitry then simply changes it back to a 1 before passing it back to the system. As you can see, with some extra information added to each row and column, error correction codes can indeed detect and correct errors on-the-fly.

Besides the ECC frames, DVDs also scramble the data in the frames using a bit-shift technique and also interleave parts of the ECC frames when they are actually recorded on the disc. These schemes serve to store the data somewhat out of sequence, preventing a scratch from corrupting consecutive pieces of data.

DVD Capacity (Sides and Layers)

Four main types of DVDs are available, categorized by whether they are single- or double-sided, and single- or dual-layered. They are designated as follows:

- *DVD-5 - 4.7GB Single-Side, Single-Layer.* A DVD-5 is constructed from two substrates bonded together with adhesive. One is stamped with a recorded layer (called Layer 0), and the other is blank. An aluminum coating typically is applied to the single recorded layer.
- *DVD-9 - 8.5GB Single-Side, Dual-Layer.* A DVD-9 is constructed of two stamped substrates bonded together to form two recorded layers for one side of the disc, along with a blank substrate for the other side. The outer stamped layer (0) is coated with a semitransparent gold coating to both reflect light if the laser is focused on it and pass light if the laser is focused on the layer below. A single laser is used to read both layers; only the focus of the laser is changed.
- *DVD-10 - 9.4GB Double-Side, Single-Layer.* A DVD-10 is constructed of two stamped substrates bonded together back to back. The recorded layer (Layer 0 on each side) usually is coated with aluminum. Note that these discs are double-sided; however, drives have a read laser only on the bottom, which means the disc must be removed and flipped to read the other side.
- *DVD-18 - 17.1GB Double-Side, Dual-Layer.* A DVD-18 combines both double layers and double sides. Two stamped layers form each side, and the substrate pairs are bonded back to back. The outer layers (Layer 0 on each side) are coated with semitransparent gold, whereas the inner layers (Layer 1 on each side) are coated with aluminum. The reflectivity of a single-layer disc is 45%85%, and for a dual-layer disc the reflectivity is 18%30%. The automatic gain control (AGC) circuitry in the drive compensates for the different reflective properties.

[Figure 11.8](#) shows the construction of each of the DVD disc types.

Figure 11.8. DVD disk types and construction.

[\[View full size image\]](#)

Note that although [Figure 11.8](#) shows two lasers reading the bottom of the dual-layer discs, in actual practice only one laser is used. Only the focus is changed to read the different layers.

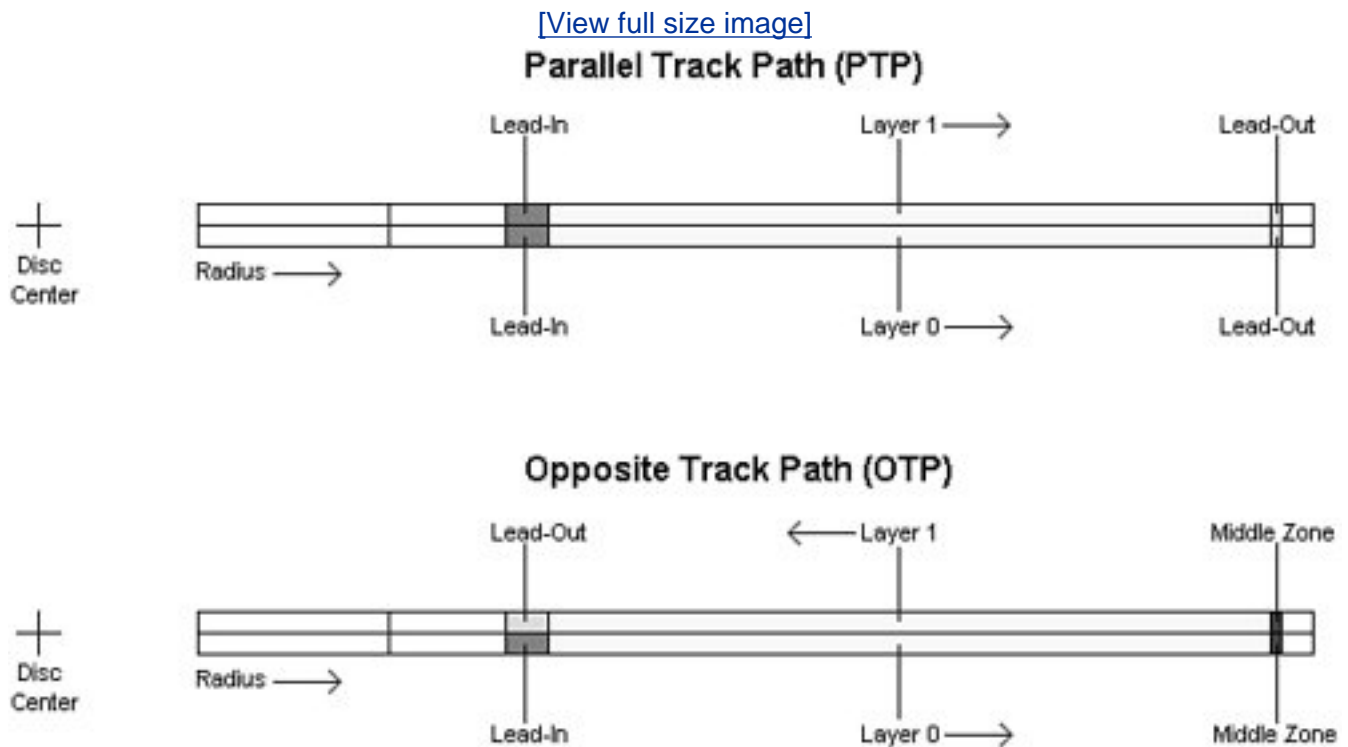

Dual-layer discs can have the layers recorded in two ways: either OTP or parallel track path (PTP). OTP minimizes the time needed to switch from one layer to the other when reading the disc. When reaching the inside of the disc (end of Layer 0), the laser pickup remains in the same location it merely moves toward the disc slightly to focus on Layer 1. When written in OTP mode, the lead-out zone toward the outer part of the disc is called a middle zone instead.

Discs written in PTP have both spiral layers written (and read) from the inside out. When changing from Layer 0 to Layer 1, PTP discs require the laser pickup to move from the outside (end of the first layer) back to the inside (start of the second layer), as well as for the focus of the laser to change. Virtually all discs are written in OTP mode to make the layer change quicker.

To allow the layers to be read more easily even though they are on top of one another, discs written in PTP mode have the spiral direction changed from one layer to the other. Layer 0 has a spiral winding clockwise (which is read counterclockwise), whereas Layer 1 has a spiral winding counterclockwise. This typically requires that the drive spin the disc in the opposite direction to read that layer, but with OTP the spiral is read from the outside in on the second layer. So Layer 0 spirals from the inside out, and Layer 1 spirals from the outside in.

[Figure 11.9](#) shows the differences between PTP and OTP on a DVD.

Figure 11.9. PTP versus OTP.

DVDs store up to 4.7GB17.1 GB, depending on the type. [Table 11.8](#) shows the precise capacities of the various types of DVDs.

Table 11.8. DVD Capacity

	Single-Layer	Dual-Layer
<hr/>		
DVD Designation	DVD-5	DVD-9
<hr/>		
B	4,695,853,056	8,535,691,264
KiB	4,585,794	8,335,636

MiB	4,478	8,140
MB	4,696	8,536
GiB	4.4	7.9
GB	4.7	8.5
<hr/>		
MPEG-2 video (approx. minutes)	133	242
MPEG-2 video (hours: minutes)	2: 13	4:02
<hr/>		
	Single-Layer	Dual-Layer
	Double-Sided	Double-Sided
<hr/>		
DVD Designation	DVD-10	DVD-18
<hr/>		
B	9,391,706,112	17,071,382,528
KiB	9,171,588	16,671,272
KB	9,391,706	17,071,383
MiB	8,957	16,281
MB	9,392	17,071
GiB	8.7	15.9
GB	9.4	17.1
<hr/>		

MPEG-2 video (approx. minutes)	266	484
MPEG-2 video (hours:minutes)	4:26	8:04

B = Byte (8 bits)

KB = Kilobyte (1,000 bytes)

KiB = Kibibyte (1,024 bytes)

MB = Megabyte (1,000,000 bytes)

MiB = Mebibyte (1,048,576 bytes)

GB = Gigabyte (1,000,000,000 bytes)

GiB = Gibibyte (1,073,741,824 bytes)

As you might notice, the capacity of dual-layer discs is slightly less than twice of single-layer discs, even though the layers take up the same space on the discs (the spiral tracks are the same length). This was done intentionally to improve the readability of both layers in a dual-layer configuration. To do this, the bit cell spacing was slightly increased, which increases the length of each pit and land. When reading a dual-layer disc, the drive spins slightly faster to compensate, resulting in the same data rate. However, because the distance on the track is covered more quickly, less overall data can be stored.

Besides the standard four capacities listed here, a double-sided disc with one layer on one side and two layers on the other can also be produced. This would be called a DVD-14 and have a capacity of 13.2GB, or about 6 hours and 15 minutes of MPEG-2 video. Additionally, 80mm discs, which store less data in each configuration than the standard 120mm discs, can be produced.

Because of the manufacturing difficulties and the extra expense of double-sided discs and the fact that they must be ejected and flipped to play both sides, most DVDs are configured as either a DVD-5 (single-sided, single-layer) or a DVD-9 (single-sided, dual-layer), which allows up to 8.5GB of data or 242 minutes of uninterrupted MPEG-2 video to be played. The 133-minute capacity of DVD-5 video discs accommodates 95% or more of the movies ever made.

Note

When you view a dual-layer DVD movie, you will see a momentary pause onscreen when the player starts to play the second layer. This is normal, and it takes so little time that if you blink, you might miss it.

Data Encoding on the Disc

As with CDs, the pits and lands themselves do not determine the bits; instead, the transitions (changes in reflectivity) from pit to land and land to pit determine the actual bits on the disc. The disc track is divided into bit cells or time intervals (T), and a pit or land used to represent data is required to be a minimum of 3T or a maximum of 11T intervals (cells) long. A 3T long pit or land represents a 1001, and a 11T long pit or land represents a 100000000001.

Data is stored using 8 to 16 modulation, which is a modified version of the eight to fourteen modulation (EFM) used on CDs. Because of this, 8 to 16 modulation is sometimes called EFM+. This modulation takes each byte (8 bits) and converts it into a 16-bit value for storage. The 16-bit conversion codes are designed so that there are never fewer than 2 or more than 10 adjacent 0 bits (resulting in no fewer than 3 or no more than 11 time intervals between 1s). EFM+ is a form of RLL encoding called RLL 2,10 (RLL x, y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread due to clocks becoming out of sync, as well as to limit the minimum and maximum frequency of transitions actually placed on the recording media. Unlike CDs, no merge bits exist between codes. The 16-bit modulation codes are designed so that they will not violate the RLL 2,10 form without needing merge bits. Because the EFM used on CDs really requires more than 17 bits for each byte (because of the added merge and sync bits), EFM+ is slightly more efficient since only slightly more than 16 bits are generated for each byte encoded.

Note that although no more than 10 0s are allowed in the modulation generated by EFM+, the sync bits added when physical sectors are written can have up to 13 0s, meaning a time period of up to 14T between 1s written on the disc and pits or lands up to 14T intervals or bit cells in length.

Blu-ray Disc

In February 2002, the leading optical storage companies formed the Blu-ray Disc Founders (BDF) and announced the initial specifications for Blu-ray Disc, a high-capacity CD/DVD-type optical disc format. By May 2002, the Blu-ray Disc (BD) specification 1.0 was released, and in April 2003, Sony released the BDZ-S77 for the Japanese market, the first commercially available BD recorder. In January 2006, the Blu-ray Disc Association also released a 2.0 specification for BD-RE discs. Blu-ray is a fully rewritable format that enables recording up to 25GB of data or up to 2 hours of high-definition video on a single-sided, single-layer 12cm diameter disc (which is the same as existing CDs and DVDs) using a 405nm blue-violet laser. Dual-layer BD recorders are also being developed and will record up to 50GB. Although backward compatibility with DVD and CD is not a requirement of the Blu-ray specification, it is a feature drive manufacturers can easily include. In fact, all the Blu-ray drives announced so far have full backward compatibility with DVD and CD formats.

One of the main applications for higher-capacity optical storage is recording high-definition TV, which takes an incredible amount of storage. Current DVD recorders can't store enough data to handle high-definition video. Blu-ray, on the other hand, is designed to store up to 2 hours of high-definition video (or more than 13 hours of standard broadcast-quality TV) on a single-layer disc, or double that when dual-layer versions become available. As with DVD, Blu-ray uses the industry-standard MPEG-2 compression technology.

The Blu-ray Disc 1.0 specification includes the following formats:

- *BD-ROM*. Read-only for prerecorded content
- *BD-R*. Recordable for PC data storage
- *BD-RW*. Rewritable for PC data storage

As of January 2006, only the BD-RE format, which is a rewritable format for HDTV recording, had been revised. The current specification is BD-RE 2.0.

Standard CDs use a 780nm (infrared) laser combined with a 0.45 numerical aperture lens, whereas DVDs use a 650nm (red) laser combined with a 0.60 numerical aperture lens. Blu-ray uses a much shorter 405nm (blue-violet) laser with a 0.85 numerical aperture lens. *Numerical aperture* is a measurement of the light-gathering capability of a lens, as well as the focal length and relative magnification. The numerical aperture of a lens is derived by taking the sine of the maximum angle of light entering the lens. For example, the lens in a CD-ROM drive gathers light at up to a 26.7° angle, which results in a numerical aperture of $\text{SIN}(26.7) = 0.45$. By comparison, the lens in a DVD drive gathers light at up to a 36.9° angle, resulting in a numerical aperture of $\text{SIN}(36.9) = 0.60$. Blu-ray drives gather light at up to a 58.2° angle, resulting in a numerical aperture of $\text{SIN}(58.2) = 0.85$. Higher numerical apertures allow increasingly oblique (angled) rays of light to enter the lens and therefore produce a more highly resolved image.

The higher the aperture, the shorter the focal length and the greater the magnification. The lens in a CD-ROM drive magnifies roughly 20 times, whereas the lens in a DVD drive magnifies about 40 times. The Blu-ray lens magnifies about 60 times. This greater magnification is necessary because the distance between tracks on a Blu-ray disc is reduced to 0.32 μm , which is almost half of that of a regular DVD. Because of the very high densities involved, a simple cartridge is normally used to hold the disc, which prevents it from being impaired by dust, fingerprints, or scratches.

The most important features of a Blu-ray disc are summarized in [Table 11.9](#).

Table 11.9. Blu-ray Disc Specifications

Specification	Value	Specification	Value
Capacity (single-layer)	23.3GB/25GB/27GB	Tracking pitch	0.32um
Capacity (dual-layer)	46.6GB/50GB/54GB	Shortest pit length	0.160/0.149/0.138um
Laser wavelength	405nm (blue-violet)	Recording density	16.8/18.0/19.5Gb/sq. in.
Lens numerical aperture	0.85	Data transfer rate	36Mbps
Cartridge dimensions	Approximately 129x131x7mm	Recording format	Phase change recording
Disc diameter	120mm	Tracking format	Groove recording
Disc thickness	1.2mm	Video format	MPEG2
Optical protection layer	0.1mm		

Blu-ray, or perhaps some other blue-laser disc drive, will eventually become the replacement for today's DVD drives. For more information about Blu-ray, see the official licensing website at www.blu-raydisc.info/, as well as the unofficial Blue-ray site at www.blu-ray.com.

HD-DVD

HD-DVD, also known as Advanced Optical Disc (AOD), is another next-generation blue laser optical disc format developed by Toshiba and NEC. HD-DVD is similar to Blu-ray (but not compatible) and also uses blue-laser technology to achieve a higher storage capacity. HD-DVD-R (recordable) versions store 15GB on a single-layer disc and 30GB on a dual-layer disc. HD-DVD-RW (rewritable) versions store 20GB on a single-layer disc and 32GB on a dual-layer disc. The DVD Forum has approved the HD-DVD format for further study as the successor to the current DVD technology. Unfortunately, the development of HD-DVD and the endorsement by the DVD Forum means that there will be another format war over the next-generation blue laser DVD drives. HD-DVD and Blu-ray products should hit the market in full force over the course of 2006, but in terms of PCs, Blu-ray has the lead, with drives and discs that have already been on the market for a while. Additionally, most of the major manufacturers have already committed to producing drives. Still, another format war is only going to cause additional confusion in the market place, just as it has with DVD recordables.

Optical Disc Formats

CD and DVD drives can use many types of disc formats and standards. The following sections discuss the formats and file systems used by CD and DVD drives, so you can make sure you can use media recorded in a particular format with your drive.

Compact Disc and Drive Formats

After Philips and Sony created the Red Book CD-DA format discussed earlier in the chapter, they began work on other format standards that would allow CDs to store computer files, data, and even video and photos. These standards control how the data is formatted so that the drive can read it, and additional file format standards can then control how the software and drivers on your PC can be designed to understand and interpret the data properly. Note that the physical format and storage of data on the disc as defined in the Red Book was adopted by all subsequent CD standards. This refers to the encoding and basic levels of error correction provided by CD-DA discs. The other "books" specify primarily how the 2,352 bytes in each sector are to be handled, what type of data can be stored, how it should be formatted, and more.

All the official CD standard books and related documents can be purchased from Philips for \$100\$150 each. See the Philips licensing site at www.licensing.philips.com for more information.

[Table 11.10](#) describes the various standard CD formats, which are discussed in more detail in the following sections.

Table 11.10. Compact Disc Formats

Format	Name	Introduced	Notes
Red Book	CD-DA (compact disc digital audio)	1980 - by Philips and Sony	<ul style="list-style-type: none">The original CD audio standard on which all subsequent CD standards are based.
Yellow Book	CD-ROM (compact disc read-only memory)	1983 - by Philips and Sony	<ul style="list-style-type: none">Specifies additional ECC and EDC for data in several sector formats, including Mode 1 and Mode 2.

Green Book	CD-i (compact disc-interactive)	1986 - by Philips and Sony	<ul style="list-style-type: none"> • Specifies an interactive audio/video standard for nonPC-dedicated player hardware (now mostly obsolete) and discs used for interactive presentations. • Defines Mode 2, Form 1 and Mode 2, Form 2 sector formats along with interleaved MPEG-1 video and ADPCM audio.
CD-ROM XA	CD-ROM XA (extended architecture)	1989 - by Philips, Sony, and Microsoft	<ul style="list-style-type: none"> • Combines Yellow Book and CD-i to bring CD-i audio and video capabilities to PCs.
Orange Book	CD-R (recordable) and CD-RW (rewritable)	1989 - by Philips and Sony (Part I/II); 1996 - by Philips and Sony (Part III)	<ul style="list-style-type: none"> • Defines single session, multisession, and packet writing on recordable discs. • Part ICD-MO (magneto-optical, withdrawn). • Part IICD-R (recordable). • Part IIICD-RW (rewritable).
Photo-CD	CD-P	1990 - by Philips and Kodak	<ul style="list-style-type: none"> • Combines CD-ROM XA with CD-R multisession capability in a standard for photo storage on CD-R discs.
White Book	Video CD	1993 - by Philips, JVC, Matsushita, and Sony	<ul style="list-style-type: none"> • Based on CD-i and CD-ROM XA. It stores up to 74 minutes of MPEG-1 video and ADPCM digital audio data.
Blue Book	CD EXTRA (formerly CD-Plus or enhanced music)	1995 - by Philips and Sony	<ul style="list-style-type: none"> • Multisession format for stamped discs; used by musical artists to incorporate videos, liner notes, and other information on audio CDs.
Purple Book	CD Double-Density	2000 by Philips and Sony	<ul style="list-style-type: none"> • Double-density (1.3GB) versions of CD-ROM, CD-R, and CD-RW (DD-ROM, DD-R, DD-RW).

Red BookCD-DA

The Red Book introduced by Philips and Sony in 1980 is the father of all compact-disc specifications because all other "books" or formats are based on the original CD-DA Red Book format. The Red Book specification includes the main parameters, audio specification, disc specification, optical stylus, modulation system, error correction system, and control and display system. The latest revision of the Red Book is dated May 1999.

For more information on the original Red Book format, see the section "CDs: A Brief History" earlier in this chapter.

Yellow BookCD-ROM

The Yellow Book was first published by Philips, Sony, and Microsoft in 1983 and has been revised and amended several times since. The Yellow Book standard took the physical format of the original CD-DA, or Red Book, standard and added another layer of error detection and correction to enable data to be stored reliably. It also added additional synchronization and header information to enable sectors to be more accurately located. Yellow Book specifies two types of sectoring called Mode 1 (with error correction) and Mode 2 which offer different levels of error detection and correction schemes. Some data (computer files, for example) can't tolerate errors. However, other data, such as a video image or sound, can tolerate minor errors. By using a mode with less error correction information, more data can be stored, but with the possibility of uncorrected errors.

In 1989, the Yellow Book was issued as an international standard by the ISO as *ISO/IEC 10149, Data Interchange on Read-Only 120mm Optical Discs (CD-ROM)*. The latest version of the Yellow Book is dated May 1999.

Green BookCD-i

The Green Book was published by Philips and Sony in 1986. CD-i is much more than just a disc format; instead it is a complete specification for an entire interactive system consisting of custom hardware (players) designed to be connected to a television, software designed to deliver video and audio together with user interactivity in real time, and the media and format. A CD-i player is actually a dedicated computer usually running a variant on the Motorola 68000 processor line, as well as a customized version of the Microware OS/9 Real Time Operating System.

CD-i enables both audio and video to share a disc and enables the information to be interleaved so as to maintain synchronization between the pictures and sounds. To fit both audio and video in the same space originally designed for just audio, compression was performed. The video was compressed using the Moving Picture Experts Group-1 (MPEG-1) compression standard, whereas the audio was compressed with adaptive differential pulse code modulation (ADPCM). ADPCM is an audio encoding algorithm that takes about half the space for the same quality of standard PCM, and even less if quality is reduced by lowering the sampling rate or bits per sample. Using ADPCM, up to 8 hours of stereo or 16 hours of mono sound can fit on one CD. The "differential" part of ADPCM refers to the fact that it records the differences between one signal and the next (using only 4-bit numbers), which reduces the total amount of data involved. ADPCM audio can be interleaved with video in CD-i (and CD-ROM XA) applications.

The Yellow Book defines two CD-ROM sector structures, called Mode 1 and Mode 2. The Green Book (CD-i) refines the Mode 2 sector definition by adding two forms, called Mode 2, Form 1 and Mode 2, Form 2. The Mode 2, Form 1 sector definition uses ECC and allows for 2,048 bytes of data storage like the Yellow Book Mode 1 sectors, but it rearranged things slightly to use the 8 formerly unused (blank or 0) bytes as a subheader containing additional information about the sector. The Mode 2, Form 2 definition drops the ECC and allows 2,324 bytes for data. Without the ECC, only video or audio information should be stored in Form 2 sectors because that type of information can tolerate minor errors.

All types of media were produced for CD-i, but because the files use the OS/9 file format, they can't be viewed by a PC without special drivers. One of the best resources for CD-i technical information, utility software, drivers, and emulators is The New International CD-I Association website at www.icdia.org.

Today, the CD-i format is largely obsolete. The last revision of the standard was produced in May 1994. Philips sold off its entire consumer CD-i catalog to Infogrames Multimedia in 1998, which now owns the rights for virtually all consumer CD-i titles ever produced. Philips made a final run of CD-i players in 1999, and it is doubtful any new ones will ever be produced. The legacy of CD-i lives on in the other formats that use specifications originally devised for CD-i, such as the Mode 2, Form 1 and Form 2 sector structures found in CD-XA and the MPEG-1 video format later used in the White Book (CD-Video).

CD-ROM XA

CD-ROM XA originally was defined in 1989 by Philips, Sony, and Microsoft as a supplement to the Yellow Book. CD-ROM XA brings some of the features originally defined in the Green Book (CD-i) to the Yellow Book (CD-ROM) standard, especially for multimedia use. CD-ROM XA adds three main features to the Yellow Book standard. The first consists of the CD-i-enhanced sector definitions (called forms) for the Mode 2 sectors; the second is a capability called interleaving (mixing audio and video information); and the third is ADPCM for compressed audio. The latest version of the CD-ROM XA standard was released in May 1991.

Interleaving

CD-ROM XA drives can employ a technique known as *interleaving*. The specification calls for the capability to encode on disc whether the data directly following an identification mark is graphics, sound, or text. Graphics can include standard graphics pictures, animation, or full-motion video. In addition, these blocks can be interleaved, or interspersed, with each other. For example, a frame of video can start a track followed by a segment of audio, which would accompany the video, followed by yet another frame of video. The drive picks up the audio and video sequentially, buffering the information in memory and then sending it along to the PC for synchronization.

In short, the data is read off the disc in alternating pieces and then synchronized at playback so that the result is a simultaneous presentation of the data. Without interleaving, the drive would have to read and buffer the entire video track before it could read the audio track and synchronize the two for playback.

Sector Modes and Forms

Mode 1 is the standard Yellow Book CD sector format with ECC and EDC to enable error-free operation. Each Mode 1 sector is broken down as shown in [Tables 11.11](#) and [11.12](#).

Table 11.11. Yellow Book Mode 1 Sector Format Breakdown

Yellow Book (CD-ROM) Sectors (Mode 1):

Q+P parity bytes	784

Subcode bytes	98

Sync bytes	12
Header bytes	4
Data bytes	2,048
EDC bytes	4
Blank (0) bytes	8
ECC bytes	276

Bytes/sector RAW (unencoded)	3,234

**Table 11.12. Yellow Book (CD-ROM)
Mode 1 Sector Format**

Sync	Header	User Data	EDC	Blank	ECC
12	4	2,048	4	8	276

In the original Yellow Book, Mode 2 was defined as a sector without any ECC or EDC. Unfortunately, Mode 1 (which had ECC and EDC) couldn't be mixed with Mode 2 sectors on the same track (program or song). To enable data with and without error detection and correction in a single track, new sector format subsets for Mode 2 sectors were added in the Green Book (CD-i) and subsequently adopted in the CD-ROM XA extensions. This enabled information that would not tolerate errors (such as programs or computer data) to be interleaved or mixed within the same track with information that would tolerate errors (such as audio or video data). These variations on Mode 2 include Form 1 and Form 2 sectors. Each Mode 2, Form 1 sector is broken down as shown in [Tables 11.13](#), [11.14](#), [11.15](#), and [11.16](#).

**Table 11.13. Green Book Mode 2 Sector
Format Breakdown**

Green Book/CD-ROM XA Sectors (Mode 2, Form 1):

Q+P parity bytes	784
Subcode bytes	98

Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,048
EDC bytes	4
ECC bytes	276

Bytes/sector RAW (unencoded)	3,234

**Table 11.14. Green Book/CD-ROM XA
(Yellow Book Extensions) Mode 2, Form 1
Sector Format**

Sync	Header	Subheader	User Data	EDC	ECC
12	4	8	2,048 bytes	4	276

**Table 11.15. Green Book Mode 2 Sector
Format Breakdown**

Green Book/CD-ROM XA Sectors (Mode 2, Form 2):

Q+P parity bytes	784
Subcode bytes	98

Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,324
EDC bytes	4

Bytes/sector RAW (unencoded)	3,234
------------------------------	-------

Table 11.16. Green Book/CD-ROM XA (Yellow Book Extensions) Mode 2, Form 2 Sector Format

Sync	Header	Subheader	User Data	EDC
12	4	8	2,324 bytes	4

Both Mode 2 sector formats add a subheader field that identifies the type of information (such as audio or video) carried in the user data field. The Form 2 sector lacks the ECC of the Form 1 sector and increases the size of the user data field instead. This type of sector is for storing audio or video data that can tolerate errors.

Because they don't use any third-level error correction, CD-ROMs that use the Mode 2, Form 2 sector format (such as MPEG video CDs) can hold more user information than other CD-ROM types in the same number of sectors and as a result also have a higher data transfer rate of 174.3KBps instead of the standard 153.6KBps. Note that Form 2 sectors are never used to store data or program files because errors can't be tolerated in that type of information. In that case, the Mode 2, Form 1 sector format would be used.

For a drive to be truly XA compatible, the audio data written in Form 2 sectors on the disc as audio must be ADPCM audiospecially compressed and encoded audio. This requires that the drive or the SCSI controller have a signal processor chip that can decompress the audio during the synchronization process.

Some earlier drives were called XA-ready, which meant they were capable of Mode 2, Form 1 and Form 2 reading but did not incorporate the ADPCM chip. This is not a significant shortcoming, however, because only certain multimedia titles use the ADPM encoding (with interleaved audio and video). The main benefit XA brought to the table was the additional sector modes and forms taken from the Green Book.

Orange Book

The Orange Book defines the standards for recordable CDs and originally was announced in 1989 by Philips and Sony. The Orange Book comes in three parts: Part I describes a format called CD-MO (magneto-optical), which was to be a rewritable format but was withdrawn before any products really came to market; Part II (1989) describes CD-R; and Part III (1996) describes CD-RW. Note that originally CD-R was referred to as CD-WO (write-once), and CD-RW originally was called CD-E (erasable).

The Orange Book Part II CD-R design is known as a WORM (write once read mostly) format. After a portion of a CD-R disc is recorded, it can't be overwritten or reused. Recorded CD-R discs are Red Book and Yellow Book compatible, which means they are readable on conventional CD-DA or CD-ROM drives. The CD-R definition in the Orange Book Part II is divided into two volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x the standard CD speed; the last revision, dated December 1998, is 3.1. Volume 2 defines

recording speeds up to 48x the standard CD speed. The latest version released, 1.2, is dated April 2002.

The Orange Book Part III describes CD-RW. As the name implies, CD-RW enables you to erase and overwrite information in addition to reading and writing. The Orange Book Part III CD-RW definition is broken into three volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x times the standard CD speed; the latest version, 2.0, is dated August 1998. Volume 2 (high-speed) defines recording speeds from 4x to 10x standard CD speed; the latest version, 1.1, is dated June 2001. Volume 3 (ultra-speed) defines recording speeds from 8x to 32x; the latest version, 1.0, is dated September 2002.

Besides the capability to record on CDs, the most important feature instituted in the Orange Book specification is the capability to perform multisession recording.

Multisession Recording Overview

Before the Orange Book specification, CDs had to be written as a single session. A *session* is defined as a lead-in, followed by one or more tracks of data (or audio), followed by a lead-out. The lead-in takes up 4,500 sectors on the disc (1 minute if measured in time or about 9.2MB worth of data). The lead-in also indicates whether the disc is multisession and what the next writable address on the disc is (if the disc isn't closed). The first lead-out on a disc (or the only one if it is a single session or Disk At Once recording) is 6,750 sectors long (1.5 minutes if measured in time or about 13.8MB worth of data). If the disc is a multisession disc, any subsequent lead-outs are 2,250 sectors long (0.5 minutes in time or about 4.6MB worth of data).

A multisession CD has multiple sessions, with each individual session complete from lead-in to lead-out. The mandatory lead-in and lead-out for each session do waste space on the disc. In fact, 48 sessions would literally use up all of a 74-minute disc even with no data recorded in each session! Therefore, the practical limit for the number of sessions you can record on a disc would be much less than that.

CD-DA and older CD-ROM drives couldn't read more than one session on a disc, so that is the way most pressed CDs are recorded. The Orange Book allows multiple sessions on a single disc. To allow this, the Orange Book defines three main methods or modes of recording:

- Disk-at-Once (DAO)
- Track-at-Once (TAO)
- Packet Writing

Disc-at-Once

Disc-at-Once means pretty much what it says: It is a single-session method of writing CDs in which the lead-in, data tracks, and lead-out are written in a single operation without ever turning off the writing laser; then the disc is closed. A disc is considered closed when the last (or only) lead-in is fully written and the next usable address on the disc is not recorded in that lead-in. In that case, the CD recorder is incapable of writing any further data on the disc. Note that it is not necessary to close a disc to read it in a normal CD-ROM drive, although if you were submitting a disc to a CD duplicating company for replication, most require that it be closed.

Track-at-Once

Multisession discs can be recorded in either Track-at-Once (TAO) or Packet Writing mode. In Track-at-Once recording, each track can be individually written (laser turned on and off) within a session, until the session

is closed. Closing a session is the act of writing the lead-out for that session, which means no more tracks can be added to that session. If the disc is closed at the same time, no further sessions can be added either.

The tracks recorded in TAO mode are typically divided by gaps of 2 seconds. Each track written has 150 sectors of overhead for run-in, run-out, pre-gap, and linking. A CD-R/RW drive can read the tracks even if the session is not closed, but to read them in a CD-DA or CD-ROM drive, the session must be closed. If you intend to write more sessions to the disc, you can close the session and not close the disc. At that point, you could start another session of recording to add more tracks to the disc. The main thing to remember is that each session must be closed (lead-out written) before another session can be written or before a normal CD-DA or CD-ROM drive can read the tracks in the session.

Packet Writing

Packet writing is a method whereby multiple writes are allowed within a track, thus reducing the overhead and wasted space on a disc. Each packet uses four sectors for run-in, two for run-out, and one for linking. Packets can be of fixed or variable length, but most drives and packet-writing software use a fixed length because dealing with file systems that way is much easier and more efficient.

With packet writing, you use the Universal Disk Format (UDF) version 1.5 or later file system, which enables the CD to be treated essentially like a big floppy drive. That is, you can literally drag and drop files to it, use the copy command to copy files onto the disc, and so on. The packet-writing software and UDF file system manage everything. If the disc you are using for packet writing is a CD-R, every time a file is overwritten or deleted, the file seems to disappear, but you don't get the space back on the disc. Instead, the file system simply forgets about the file. If the disc is a CD-RW, the space is indeed reclaimed and the disc won't be full until you literally have more than the limit of active files stored there.

Unfortunately, Windows versions up through Windows XP don't support packet writing or the UDF file system directly, so drivers must be loaded to read packet-written discs and a packet-writing application must be used to write them. Fortunately, though, these typically are included with CD-RW drives. One of the most popular packet-writing programs is DirectCD from Roxio. You can even download a universal UDF reader application from Roxio for free that enables you to read UDF 1.5 (packet-written) discs on any CD-ROM or CD-RW drive.

Note

Windows XP also has limited CD-RW support in the form of something called IMAPI (image mastering application program interface), which enables data to be temporarily stored on the hard drive (staged) before being written to the CD in one session. Additional sessions can be written to the same disc, but a 50MB overhead exists for each session. This gives some of the appearance of packet writing, but it is not really the same thing. To read packet-written discs in the UDF 1.5 or later format, you must install a UDF reader just as with previous versions of Windows. Instead of using IMAPI, I recommend installing a third-party CD-mastering program that also includes packet-writing UDF support, such as Roxio's Easy Media Creator or Ahead Nero.

When you remove a packet-written disc from the drive, the packet-writing software first asks whether you want the files to be visible to normal CD-ROM drives. If you do then the session must be closed. Even if the session is closed, you can still write more to the disc later, but there is an overhead of wasted space every time you close a session. If you are going to read the disc in a CD-RW drive, you don't have to close the session because it will be capable of reading the files even if the session isn't closed.

A newer standard called Mount Rainier adds even more capability to packet writing and is one of the most important developments in CD and DVD drives. With Mount Rainier, packet writing can become an official part of the operating system and the drives can support the defect management necessary to make them usable as removable storage in the real world. For more information, see the section "Mount Rainier" later in this chapter.

Note

Microsoft has released updates for Windows XP that add native support for the Mount Rainier standard, which supports full drag-and-drop packet writing through CD-MRW drives as well as DVD+MRW drives.

Photo CD

First announced back in 1990 but not available until 1992, Photo CD is a standard for CD-R discs and drives to store photos. The current version 1.0 of the Photo CD standard was published in December 1994. You simply drop off a roll of film at a participating Kodak developer, and they digitize and store the photos on a specially formatted CD-R disc called a Photo CD, which you can then read on virtually any CD-ROM drive connected to a PC running the appropriate software. Originally, Kodak sold Photo CD "players" designed to display the photos to a connected TV, but these have since been dropped in favor of simply using a PC with software to decode and display the photos.

Perhaps the main benefit Photo CD has brought to the table is that it was the first CD format to use the Orange Book Part II (CD-R) specification with multisession recordings. Additionally, the data is recorded in CD-ROM XA Mode 2, Form 2 sectors so more photo information could be stored on the disc.

Using the Photo CD software, you can view your photographs at any one of several resolutions and manipulate them using standard graphics software packages.

When you drop off your roll of film, the Kodak developers produce prints as they normally do. After prints are made, they scan the prints with ultra-high-resolution scanners. To give you an idea of the amount of information each scan carries, one color photograph can take 15MB20MB of storage. The compressed, stored images are then encoded onto special writable CDs, and the finished product is packaged and shipped back to your local developer for pickup. Some developers can do the scanning onsite.

Photo CD Disc Types

The images on the disc are compressed and stored using Kodak's own PhotoYCC encoding format, which includes up to six resolutions for each image, as shown in [Table 11.17](#). Kodak has defined several types of Photo CDs to accommodate the needs of various types of users. The Photo CD Master disc is the standard consumer format and contains up to 100 photos in all the resolutions shown in the table except for base x64.

Table 11.17. Photo CD Resolutions

Base	Resolution (Pixels)	Description
/16	128x192	Thumbnail
/4	256x384	Thumbnail
x1	512x768	TV resolution
x4	1,024x1,536	HDTV resolution
x16	2,048x3,072	Print size
x64	4,096x6,144	Pro Photo CD master only

The various resolutions supply you with images appropriate for various applications. If, for example, you wanted to include a Photo CD image on a web page, you would choose a low-resolution image. A professional photographer shooting photos for a print ad would want to use the highest resolution possible.

The Pro Photo CD Master disc is intended for professional photographers using larger film formats, such as 70mm, 120mm, or 4"x5". This type of disc adds an even higher-resolution image (4,096x6,144 pixels) to those already furnished on the Photo CD Master disc. Because of this added high-resolution image, this type of disc can hold anywhere from 25 to 100 images, depending on the film format.

The Photo CD Portfolio disc is designed for interactive presentations that include sound and other multimedia content. The high-resolution images that take up the most space are not necessary here, so this type of disc can contain up to 700 images, depending on how much other content is included.

Multisession Photo CDs

One breakthrough of the Photo CD concept is that each of the disc types is capable of containing multiple sessions. Because the average consumer wouldn't usually have enough film processed to fill an entire disc, you can bring back your partially filled CDs each time you have more film to develop. A new session can then be added to your existing CD until the entire disc is filled. You pay less for the processing because a new CD is not necessary, and all your images are stored on a smaller number of discs.

Any XA-compliant or XA-ready CD-ROM drive can read the multiple sessions on a Photo CD disc, and even if your drive is not multisession capable, it can still read the first session on the disc. If this is the case, you must purchase a new disc for each batch of film you process, but you can still take advantage of Photo CD technology.

Kodak provides software that enables you to view the Photo CD images on your PC and licenses a Photo CD import filter to the manufacturers of many desktop publishing, image-editing, and paint programs. Therefore, you can modify your Photo CD images using a program such as Adobe Photoshop and integrate them into documents for printing or electronic publication with a page layout program such as Adobe PageMaker.

Picture CD

Although Kodak still offers Photo CD services, the high cost has led to limited popularity. Kodak now offers the simpler Picture CD service. Unlike Photo CD, Picture CD uses the industry-standard JPEG file format. It

uses a CD-R, with up to 40 images stored at a single medium-resolution scan of 1,024x1,536 pixels. This resolution is adequate for 4"x6" and 5"x7" prints. The images can also be made available via Kodak PhotoNet, where the same images are posted online and can be downloaded. In addition, Kodak has a service called Picture Disk that stores up to 28 images on a 1.44MB floppy disk at a resolution of 400x600, suitable for screensavers and slide shows.

The software provided with Picture CD enables the user to manipulate images with various automatic or semiautomatic operations, but unlike Photo CD, the standard JPEG (JPG) file format used for storage enables any popular image-editing program to work with the images without conversion. Although the image quality of Picture CD isn't as high as with Photo CD, the much lower price of the service should make it far more popular with amateur photographers. Services similar to Picture CD are also offered by Fujifilm and Agfa, and some stores allow you to order Kodak Picture CD with your choice of store-brand or Kodak film processing.

White BookVideo CD

The White Book was introduced in 1993 by Philips, JVC, Matsushita, and Sony. It is based on the Green Book (CD-i) and CD-ROM XA standards and allows for storing up to 74 minutes of MPEG-1 video and ADPCM digital audio data on a single disc. The latest version (2.0) was released in April 1995. Video CD 2.0 supports MPEG-1 compression with a 1.15Mbps bit rate. The screen resolution is 352x240 for NTSC format and 352x288 for European PAL format. In addition, it supports Dolby Pro Logiccompatible stereo sound.

You can think of video CDs as a sort of poor man's DVD format, although the picture and sound quality can actually be quite goodcertainly better than VHS or most other videotape formats. You can play video CDs on virtually any PC with a CD-ROM drive using the free Windows Media Player (other media player applications can be used as well). They also can be played on most DVD players and even some game consoles, such as the Playstation (with the correct options). Video CDs are an especially big hit with people who travel with laptop computers, and the prerecorded discs are much cheaper than DVDmany cost as little as \$5.

Super Video CD

The Super Video CD specification 1.0, published in May 1999, is an enhanced version of the the White Book Video CD specification. It uses MPEG-2 compression, an NTSC screen resolution of 480x480, and a PAL screen resolution of 480x576; it also supports MPEG-2 5.1 surround sound and multiple languages.

Most home DVD-creation programs can create Video CDs or Super Video CDs.

Blue BookCD EXTRA

Manufacturers of CD-DA media were looking for a standard method to combine both music and data on a single CD. The intention was for a user to be able to play only the audio tracks in a standard audio CD player while remaining unaware of the data track. However, a user with a PC or dedicated combination audio/data player could access both the audio and data tracks on the same disc.

The fundamental problem with nonstandard mixed-mode CDs is that if or when an audio player tries to play the data track, the result is static that could conceivably damage speakers and possibly hearing if the volume level has been turned up. Various manufacturers originally addressed this problem in different ways, resulting in a number of confusing methods for creating these types of discs, some of which still allowed the data tracks to be accidentally "played" on an audio player. In 1995, Philips and Sony developed the CD EXTRA specification, as defined in the Blue Book standard. CDs conforming to this specification

usually are referred to as CD EXTRA (formerly called CD Plus or CD Enhanced Music) discs and use the multisession technology defined in the CD-ROM XA standard to separate the audio and data tracks. These are a form of stamped multisession disc. The audio portion of the disc can consist of up to 98 standard Red Book audio tracks, whereas the data track typically is composed of XA Mode 2 sectors and can contain video, song lyrics, still images, or other multimedia content. Such discs can be identified by the CD EXTRA logo, which is the standard CD-DA logo with a plus sign to the right. Often the logo or markings on the disc package are overlooked or somewhat obscure, and you might not know that an audio CD contains this extra data until you play it in a CD-ROM drive.

A CD EXTRA disc normally contains two sessions. Because audio CD players are only single-session capable, they play only the audio session and ignore the additional session containing the data. A CD-ROM drive in a PC, however, can see both sessions on the disc and access both the audio and data tracks.

Note

Many artists have released audio CDs in the CD EXTRA format that include things such as lyrics, video, artist bio, photos, and so on in data files on the disc. *Tidal* by Fiona Apple (released in 1996) was one of the first CD EXTRA discs from Sony Music. There have been many CD EXTRA releases since then. For examples of other CD EXTRA (Enhanced CD) discs, including current releases, see www.musicfan.com.

Purple Book

The Purple Book defines the standards for double-density CD-ROM (DDCD), CD-R (DDCD-R), and CD-RW (DDCD-RW) media and drives. It was announced by Sony and Philips in July 2000, and the current 1.0 standard was released in July 2001.

Purple Bookcompliant rewritable drives can read and write standard CD, CD-R, and CD-RW media and achieve their higher 1.3GB (versus 650MB for standard drives) by modifying the following features of existing CD-ROM, CD-R, and CD-RW standards:

- The track pitch has been reduced from 1.6 micrometers to 1.1 micrometers, and the minimum pit length has been reduced from 0.833 micrometers to 0.623 micrometers to enable double-density recording.
- CIRC7, instead of regular CIRC, error correction is used.
- An expanded ATIP address format is used.

DD drives support digital rights management. They are designed to prevent the creation of DD music CDs. [Tables 11.18](#) and [11.19](#) provide the details of the sector format used by DD drives.

Table 11.18. Purple Book Mode 2 Sector Format Breakdown

Purple Book/DD CD-ROM Sectors (Mode 2, Form 2):

Q+P parity bytes	276
Subcode bytes	98

Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,048
EDC bytes	4

Bytes/sector RAW (unencoded)	2,352

Table 11.19. Purple Book/DD CD-ROM Mode 2, Form 2 Sector Format

Sync	Header	Subheader	User Data	EDC
12	4	8	2,048 bytes	4

Although DDCD drives have twice the capacity of traditional drives, very few of them were sold. Sony offered several models in 2001 but has since discontinued them, although DDCD media is still available.

CD-ROM File Systems

Manufacturers of early CD-ROM discs required their own custom software to read the discs. This is because the Yellow Book specification for CD-ROM details only how data sectorsrather than audio sectorscan be stored on a disc and did not cover the file systems or deal with how data should be stored in files and how these should be formatted for use by PCs with different operating systems. Obviously, noninterchangeable file formats presented an obstacle to the industry-wide compatibility for CD-ROM applications.

In 19851986, several companies got together and published the High Sierra file format specification, which finally enabled CD-ROMs for PCs to be universally readable. That was the first industry-standard CD-ROM file system that made CD-ROMs universally usable in PCs. Today several file systems are used on CDs, including

- High Sierra
- ISO 9660 (based on High Sierra)
- Joliet
- UDF (Universal Disk Format)
- Mac HFS (Hierarchical File Format)

- Rock Ridge
- Mount Rainier

Not all CD file system formats can be read by all operating systems. [Table 11.20](#) shows the primary file systems used and which operating systems support them.

Table 11.20. CD File System Formats

CD File System	DOS/Win 3.x	Win 9x/Me	Win NT/2000/XP	Mac OS
High Sierra	Yes	Yes	Yes	Yes
ISO 9660	Yes	Yes	Yes	Yes
Joliet	Yes [1]	Yes	Yes	Yes [1]
UDF	No	Yes [2]	Yes [2]	Yes [2]
Mac HFS	No	No	No	Yes
Rock Ridge	Yes [1]	Yes [1]	Yes [1]	Yes [1]
Mount Rainier	No	Yes [3]	Yes [3]	Yes [3]

^[1] A short name, such as (SHORTN~1.TXT), will be shown in place of long filenames.

^[2] Only if a third-party UDF reader is installed.

^[3] Requires Mount Rainier (also called EasyWrite) hardware and driver software (Win98 or above) or a third-party reader program.

Note

The Mac HFS and Unix Rock Ridge file systems are not supported by PC operating systems such as DOS or Windows and therefore are not covered in depth here.

High Sierra

To make CD-ROM discs readable on all systems without having to develop custom file systems and drivers, it was in the best interests of all PC hardware and software manufacturers to resolve the CD-ROM file format standardization issue. In 1985, representatives from TMS, DEC, Microsoft, Hitachi, LaserData, Sony, Apple, Philips, 3M, Video Tools, Reference Technology, and Xebec met at what was then called the High

Sierra Hotel and Casino in Lake Tahoe, Nevada, to create a common logical format and file structure for CD-ROMs. In 1986, they jointly published this standard as the "Working Paper for Information Processing: Volume and File Structure of CD-ROM Optical Discs for Information Exchange (1986)." This standard was subsequently referred to as the High Sierra format.

This agreement enabled all drives using the appropriate driver (such as MSCDEX.EXE supplied by Microsoft with DOS) to read all High Sierra format discs, opening the way for the mass production and acceptance of CD-ROM software publishing. Adoption of this standard also enabled disc publishers to provide cross-platform support for their software and easily manufacture discs for DOS, Unix, and other operating system formats. Without this agreement, the maturation of the CD-ROM marketplace would have taken years longer and the production of CD-ROM-based information would have been stifled.

The High Sierra format was submitted to the International Organization for Standardization (ISO). Two years later (in 1988), with several enhancements and changes, it was republished as the ISO 9660 standard. ISO 9660 was not exactly the same as High Sierra, but all drivers that would read High Sierraformatted discs were quickly updated to handle both ISO 9660 and the original High Sierra format on which it was based.

For example, Microsoft wrote the MSCDEX.EXE (Microsoft CD-ROM extensions) driver in 1988 and licensed it to CD-ROM hardware and software vendors to include with their products. It wasn't until 1993 when MS-DOS 6.0 was released that MSCDEX was included with DOS as a standard feature. MSCDEX enables DOS to read ISO 9660formatted (and High Sierraformatted) discs. This driver works with the AT Attachment Packet Interface (ATAPI) or Advanced SCSI Programming Interface (ASPI) hardware-level device driver that comes with the drive. Microsoft built ISO 9660 and Joliet file system support directly into Windows 95 and later, with no additional drivers necessary.

ISO 9660

The ISO 9660 standard enabled full cross compatibility among different computer and operating systems. ISO 9660 was released in 1988 and was based on the work done by the High Sierra group. Although based on High Sierra, ISO 9660 does have some differences and refinements. It has three levels of interchange that dictate the features that can be used to ensure compatibility with different systems.

ISO 9660 Level 1 is the lowest common denominator of all CD file systems and is capable of being read by almost every computer platform, including Unix and Macintosh. The downside of this file system is that it is very limited with respect to filenames and directories. Level 1 interchange restrictions include

- Only uppercase characters AZ, numbers 09, and the underscore (_) are allowed in filenames.
- 8.3 characters maximum for the name.extension (based on DOS limits).
- Directory names are eight characters maximum (no extension allowed).
- Directories are limited to eight levels deep.
- Files must be contiguous.

Level 2 interchange rules have the same limitations as Level 1, except that the filename and extension can be up to 30 characters long (both added together, not including the . separator). Finally, Level 3 interchange rules are the same as Level 2 except that files don't have to be contiguous.

Note that Windows 95 and later versions enable you to use file and folder names up to 255 characters long, which can include spaces as well as lowercase and many other characters not allowed in ISO 9660. To maintain backward compatibility with DOS, Windows 95 and later associate a short 8.3 format filename as an alias for each file that has a longer name. These alias short names are created automatically by Windows and can be viewed in the Properties for each file or by using the **DIR** command at a command

prompt. To create these alias names, Windows truncates the name to six (or fewer) characters followed by a tilde (~) and a number starting with 1 and truncates the extension to three characters. Other numbers are used in the first part if other files that would have the same alias when truncated already exist. For example, the filename **This is a test** gets **THISIS~1.TES** as an alias.

This filename alias creation is independent of your CD drive, but it is important to know that if you create or write to a CD using the ISO 9660 format using Level 1 restrictions, the alias short names are used when recording files to the disc, meaning any long filenames will be lost in the process. In fact, even the alias short name will be modified because ISO 9660 Level 1 restrictions don't allow a tilde character that character is converted to an underscore in the names written to the CD.

The ISO 9660 data starts at 2 seconds and 16 sectors into the disc, which is also known as *logical sector 16 of track one*. For a multisession disc, the ISO 9660 data is present in the first data track of each session containing CD-ROM tracks. This data identifies the location of the volume area where the actual data is stored. The system area also lists the directories in this volume as the volume table of contents (VTOC), with pointers or addresses to various named areas, as illustrated in [Figure 11.10](#). A significant difference between the CD directory structure and that of a normal hard disk is that the CD's system area also contains direct addresses of the files within the subdirectories, allowing the CD to seek specific sector locations on the spiral data track. Because the CD data is all on one long spiral track, when speaking of tracks in the context of a CD, we're actually talking about sectors or segments of data along that spiral.

Figure 11.10. A diagram of basic ISO 9660 file organizational format.

To put the ISO 9660 format in perspective, the disc layout is roughly analogous to that of a floppy disk. A floppy disk has a system track that not only identifies itself as a floppy disk and reveals its density and operating system, but also tells the computer how it's organized (into directories, which are made up of files).

Joliet

Joliet is an extension of the ISO 9660 standard that Microsoft developed for use with Windows 95 and later. Joliet enables CDs to be recorded using filenames up to 64 characters long, including spaces and other characters from the Unicode international character set. Joliet also preserves an 8.3 alias for those programs that can't use the longer filenames.

In general, Joliet features the following specifications:

- File or directory names can be up to 64 Unicode characters (128 bytes) in length.
- Directory names can have extensions.
- Directories can be deeper than eight levels.
- Multisession recording is inherently supported.

Tip

Because Joliet supports a shorter path than Windows 9x and newer versions, you might have difficulties mastering a Joliet-format CD that contains extremely long pathnames. I recommend you shorten folder names in the file structure you create with the CD mastering software to avoid problems. Unfortunately, many CD mastering programs don't warn you about a pathname that is too long until after the burning process starts.

Due to backward-compatibility provisions, systems that don't support the Joliet extensions (such as older DOS systems) should still be capable of reading the disc. However, it will be interpreted as an ISO 9660 format using the short names instead.

Note

A bit of trivia: "Chicago" was the code name used by Microsoft for Windows 95. Joliet is the town outside of Chicago where Jake was locked up in the movie *The Blues Brothers*.

Universal Disk Format

UDF is a relatively new file system created by the Optical Storage Technology Association (OSTA) as an industry-standard format for use on optical media such as CD-ROM and DVD. UDF has several advantages over the ISO 9660 file system used by standard CD-ROMs but is most noted because it is designed to work with packet writing, a technique for writing small amounts of data to a CD-R/RW disc, treating it much like a standard magnetic drive.

The UDF file system allows long filenames up to 255 characters per name. There have been several versions of UDF, with most packet-writing software using UDF 1.5 or later. Packet-writing software such as DirectCD from Roxio writes in the UDF file system. However, standard CD-ROM drives, drivers, or operating systems such as DOS can't read UDF-formatted discs. Recordable drives can read them, but regular CD-ROM drives must conform to the MultiRead specification (see the section "MultiRead Specifications," later in this chapter) to be capable of reading UDF discs.

After you are sure that your drive can read UDF, you must check the OS. Most operating systems can't read UDF natively; the support has to be added via a driver. DOS can't read UDF at all; however, with Windows 95 and later, UDF-formatted discs can be read by installing a UDF driver. Typically, such a driver is included with the software that comes with most CD-RW drives. If you don't have a UDF driver, you can download one for free from Roxio at www.roxio.com. The Roxio UDF Reader is included with DirectCD 3.0 and later. After the UDF driver is installed, you do not need to take any special steps to read a UDF-formatted disc.

The driver will be in the background waiting for you to insert a UDF-formatted disc.

You can close a DirectCD for Windows disc to make it readable in a normal CD-ROM drive, which converts the filenames to Joliet format and causes them to be truncated to 64 characters.

You can download the latest (revision 2.01) version of the Universal Disk Format from the OSTA website at www.osta.org/specs/index.htm.

Macintosh HFS

HFS is the file system used by the Macintosh OS. HFS can also be used on CD-ROMs; however, if that is done, they will not be readable on a PC. A hybrid disc can be produced with both Joliet and HFS or ISO 9660 and HFS file systems, and the disc would then be readable on both PCs and Macs. In that case, the system will see only the disc that is compatible, which is ISO 9660 or Joliet in the case of PCs.

Rock Ridge

The Rock Ridge Interchange Protocol (RRIP) was developed by an industry consortium called the Rock Ridge group. It was officially released in 1994 by the IEEE CD-ROM File System Format Working Group and specifies an extension to the ISO 9660 standard for CD-ROM that enables the recording of additional information to support Unix/POSIX file system features. Neither DOS nor Windows include support for the Rock Ridge extensions. However, because it is based on ISO 9660, the files are still readable on a PC and the RRIP extensions are simply ignored.

Note

An interesting bit of trivia is that the Rock Ridge name was taken from the fictional Western town in the movie *Blazing Saddles*.

Mount Rainier

Mount Rainier is a recent standard being promoted by Philips, Sony, Microsoft, and HP (Compaq). Also called EasyWrite (see [Figure 11.11](#)), Mount Rainier enables native operating system support for data storage on CD-RW and DVD+RW. This makes the technology much easier to use (no special drivers or packet-writing software is necessary) and enables CD-RW and DVD+RW drives to become fully integrated storage solutions.

Figure 11.11. The EasyWrite logo is used on CD-RW and DVD+R/RW drives manufactured in 2003 and beyond that support the Mount Rainier standard.

The main features of Mount Rainier are as follows:

- *Integral defect management.* Standard drives rely on driver software to manage defects.
- *Direct addressing at the 2KB sector level to minimize wasted space.* Standard CD-RW media uses a block size of 64KB.
- *Background formatting so that new media can be used in seconds after first insertion.* Standard CD-RW formatting can take up to 45 minutes depending on drive speed.
- *Standardized command set.* Standard software cannot work with new drives until revised command files are available.
- *Standardized physical layout.* Differences in standard UDF software can make reading media written by another program difficult.

To use Mount Rainier, you must have a drive that supports the standard. These are sometimes called CD-MRW or DVD+MRW drives and might instead bear either the Mount Rainier or EasyWrite logo. Some existing CD-RW drives can be updated to MRW status by reflashing the firmware in the drive; however, most older drives will need to be replaced instead.

Also required is software support directly in the operating system (such as with Windows XP or later), or software support can be added via a third-party add-on application for older operating systems.

Software Architects (www.softarch.com) produces WriteCD-RW Pro! Software, which enables interchange between Mount Rainier and conventional UDF media, as well as between UDF media written with different programs and to different standards.

The first Mount Rainier drive (Philips RWDV1610B) was released in April 2002, and since then many more have followed. Because only minor changes are required in the drive circuitry and firmware to enable Mount Rainier support, many newer drives include Mount Rainier capability; check the drive vendor's website or manual to determine compatibility. In addition, the DVD+RW standard was designed with Mount Rainier compatibility in mind; defect management was included inherently from the beginning. (DVD-RW drives don't support defect management, so they are not compatible with Mount Rainier.) The first DVD+RW drives with Mount Rainier/EasyWrite compatibility began shipping in early 2003.

Because Mount Rainier essentially makes CD-MRW and DVD+MRW drives function as high-capacity replacements for floppy, Zip, and SuperDisk drives, it won't be long before those are but a distant memory.

The latest version of the Mount Rainier specification, version 1.1., includes DVD+RW as well as CD-RW drives. It can be ordered from the Philips Intellectual Property and Standards website (www.licensing.philips.com). For more information, go to the Mount Rainier website at www.mt-rainier.org.

DVD Formats and Standards

As with the CD standards, the DVD standards are published in reference books produced mainly by the DVD Forum, but also by other companies.

The DVD-Video and DVD-ROM standards are pretty well established, but recordable DVD technology is still evolving. The standards situation for recordable DVD is more confusing than usual, especially because there are at least four different (and somewhat incompatible) recording formats! It remains to be seen which will have the best support and become the most popular, but so far the DVD-RW and DVD+RW formats are both very popular. However, DVD+RW looks to be by far the most promising for the future with higher

speed, features that make it ideal for both video and data recording, higher compatibility with existing DVD players and drives, and finally Microsoft's endorsement via including support in upcoming versions of Windows. At this point, the only type of recordable DVD I recommend for both home DVD recorders and PC-based DVD recordable drives are units that conform to the DVD+RW format. That also includes DVD±R/RW drives (which support both formats in a single unit), making them essentially compatible with everything. I recommend avoiding drives that do not support the DVD+R/RW format.

The current standard DVD formats are shown in [Table 11.21](#).

Table 11.21. Standard DVD Formats and Capacities

Format	Disc Size	Sides	Layers	Data Capacity	MPEG-2 Video Capacity
<i>DVD-ROM Formats and Capacities</i>					
DVD-5	120mm	Single	Single	4.7GB	2.2 hours
DVD-9	120mm	Single	Double	8.5GB	4.0 hours
DVD-10	120mm	Double	Single	9.4GB	4.4 hours
DVD-14	120mm	Double	Both	13.2GB	6.3 hours
DVD-18	120mm	Double	Double	17.1GB	8.1 hours
DVD-1	80mm	Single	Single	1.5GB	0.7 hours
DVD-2	80mm	Single	Double	2.7GB	1.3 hours
DVD-3	80mm	Double	Single	2.9GB	1.4 hours
DVD-4	80mm	Double	Double	5.3GB	2.5 hours
<i>Recordable DVD Formats and Capacities</i>					
DVD-R 1.0	120mm	Single	Single	3.95GB	1.9 hours
DVD-R 2.0	120mm	Single	Single	4.7GB	2.2 hours
DVD-RAM 1.0	120mm	Single	Single	2.58GB	N/A
DVD-RAM 1.0	120mm	Double	Single	5.16GB	N/A
DVD-RAM 2.0	120mm	Single	Single	4.7GB	N/A
DVD-RAM 2.0	120mm	Double	Single	9.4GB	N/A
DVD-RAM 2.0	80mm	Single	Single	1.46GB	N/A
DVD-RAM 2.0	80mm	Double	Single	2.65GB	N/A
DVD-RW 2.0	120mm	Single	Single	4.7GB	N/A
DVD+RW 2.0	120mm	Single	Single	4.7GB	2.2hours

DVD+RW 2.0	120mm	Double	Single	9.4GB	4.4 hours
DVD+R 1.0	120mm	Single	Single	4.7GB	2.2 hours

CD-ROM Formats and Capacities (for comparison)

CD-ROM/R/RW	120mm	Single	Single	0.737GB	N/A
CD-ROM/R/RW	80mm	Single	Single	0.194GB	N/A

With advancements coming in blue-light lasers, this capacity will be increased several-fold in the future with an HD-DVD format that can store up to 20GB per layer. Prototype players have already been shown by major manufacturers, although you shouldn't expect to see HD-DVD on the market just yet.

DVD drives are fully backward-compatible and as such are capable of playing today's CD-ROMs as well as audio CDs. When playing existing CDs, the performance of current models is equivalent to a 40x or faster CD-ROM drive. Therefore, users who currently own slower CD-ROM drives might want to consider a DVD drive instead of upgrading to a faster CD-ROM drive. Several manufacturers have announced plans to phase out their CD-ROM drive products in favor of DVD. DVD is rapidly making CD-ROMs obsolete in the same way that audio CDs displaced vinyl records in the 1980s. The only thing keeping the CD-ROM format alive is the battle between competing DVD recordable standards and the fact that CD-R and CD-RW are rapidly becoming the de facto replacements for the floppy drive.

The current crop of DVD drives features several improvements over the first-generation models of 1997. Those units were expensive, slow, and incompatible with either CD-R or CD-RW media. Many early units asked your overworked video card to try to double as an MPEG decoder to display DVD movies, with mediocre results in speed and image quality. As is often the case with "leading-edge" devices, their deficiencies make them eminently avoidable.

Many PC vendors have integrated DVD-ROM drives into their new high-end computers, usually as an option. Originally, most of these installations included an MPEG-2 decoder board for processing the compressed video on DVDs. This offloads the intensive MPEG calculations from the system processor and enables the display of full-screen, full-motion video on a PC. After processors crossed 400MHz in speed, performing MPEG-2 decoding reliably in software became possible, so any systems faster than that usually don't include a hardware decoder card.

Some manufacturers of video display adapters have begun to include MPEG decoder hardware on their products. These adapters are known as "DVD MPEG-2 accelerated" and call for some of the MPEG decoding tasks to be performed by software. Any software decoding involved in an MPEG solution places a greater burden on the main system processor and can therefore yield less satisfactory results on slower systems.

DIVX (Discontinued Standard)

DIVX (Digital Video Express) was a short-lived proprietary DVD format developed by Digital Video Express (a Hollywood law firm) and Circuit City. It was discontinued on June 16, 1999, less than a year after it was released.

The name now lives on as an open encoding standard for DVD video. However, this encoding standard actually has no relation to the original DIVX format other than the name.

Note

More detailed coverage of DIVX is included in [Chapter 13](#) of the 11th and 12th editions of this book, both of which are included in their entirety on the disc accompanying this book.

DVD Drive Compatibility

When DVD drives first appeared on the market, they were touted to be fully backward-compatible with CD-ROM drives. Although that might be the case when reading commercially pressed CD-ROM discs, that was not necessarily true when reading CD-R or CD-RW media. Fortunately, the industry has responded with standards that let you know in advance how compatible your DVD drive will be. These standards are called *MultiRead* for computer-based drives and *MultiPlay* for consumer standalone devices, such as DVD-Video or CD-DA players. See the section "MultiRead Specifications," later in this chapter.

DVD Movie Playback on a PC

Almost all DVD-ROM and rewritable DVD drives (except for some DVD-RAM drives) include a DVD playback program such as MyDVD or SoftDVD. These programs enable you to interact with a DVD movie the same way you would if it were being played through a DVD player.

However, if your video card doesn't have built-in MPEG-2 decoding, you might want to consider upgrading to a better video card that has this feature (all recent ATI and NVIDIA chipsets support MPEG-2 decoding in hardware) or install a separate MPEG-2 decoder. Hardware decoding is very important for best quality, particularly if your processor has a clock speed below 1GHz (it's possible with a 400MHz machine, but at least 1GHz is ideal).

If you are using a hardware decoder, it requires an open PCI expansion slot, as well as an interrupt request (IRQ) resource from your system. Also, to view the movies on your PC's display, you must somehow connect the decoder card to your existing video card. This can be accomplished via an internal connection to the card, or it can use a loop-through connection to the monitor port on the back of the card. Some video cards include MPEG-2 decoders (players) built in. [Table 11.22](#) compares MPEG decoder hardware (built in to a separate card or integrated into a video card's 3D accelerator chip) with MPEG player.

Table 11.22. MPEG Decoder Hardware Versus MPEG Player Software

Consideration	MPEG Decoder	MPEG Player Software
PCI/AGP slot usage	One for decoder; one for VGA ^[*] or integrated into video chipset	Video card (or integrated video)
Movie image quality	High	Varies
Playback speed	High	Varies
MPEG game compatibility	Yes	No

[*] *If integrated into graphics card, uses one slot (AGP or PCI) only*

DVD Copy Protection

DVD video discs employ several levels of protection that are mainly controlled by the DVD Copy Control Association (DVD CCA) and a third-party company called Macrovision. This protection typically applies only to DVD-Video discs, not DVD-ROM software. So, for example, copy protection might affect your ability to make backup copies of *The Matrix*, but it won't affect a DVD encyclopedia or other software application distributed on DVD-ROM discs.

Note that every one of these protection systems has been broken, so with a little extra expense or the correct software, you can defeat the protection and make copies of your DVDs either to other digital media (hard drive, DVD+RW, CD-R/RW, and so on) or analog media (such as a VHS or other tape format).

A lot of time and money are wasted on these protection schemes, which can't really foil the professional bootleggers willing to spend the time and money to work around them. But they can make it difficult for the average person to legitimately back up his expensive media.

The three main protection systems used with DVD-Video discs are:

- Regional Playback Control (RPC)
- Content Scrambling System (CSS)
- Analog Protection System (APS)

Caution

The Digital Millennium Copyright Act (DMCA) signed into law in 1998 prohibits the breaking of copy-protection schemes or the distribution of information (such as tools, website links, and so forth) on how to break these schemes.

Regional Playback Control

Regional playback was designed to allow discs sold in specific geographical regions of the world to play only on players sold in those same regions. The idea was to allow a movie to be released at different times in different parts of the world and to prevent people from ordering discs from regions in which the movie had not been released yet.

Eight regions are defined in the RPC standard. Discs (and players) usually are identified by a small logo or label showing the region number superimposed on a world globe. Multiregion discs are possible, as are discs that are not region locked. If a disc plays in more than one region, it has more than one number on the globe. The regions are

- *Region Code 1.* United States, Canada, U.S. Territories
- *Region Code 2.* Japan, Europe, South Africa, and the Middle East
- *Region Code 3.* Southeast Asia and East Asia
- *Region Code 4.* Australia, New Zealand, Pacific Islands, Central America, Mexico, South America,

and the Caribbean

- *Region Code 5*. Eastern Europe (east of Poland and the Balkans), Indian subcontinent, Africa, North Korea, and Mongolia
- *Region Code 6*. China and Tibet
- *Region Code All*. Special international or mobile venues, such as airplanes, cruise ships, and so on

The region code is embedded in the hardware of DVD video players. Most players are preset for a specific region and can't be changed. Some companies who sell the players modify them to play discs from all regions; these are called *region-free* or *code-free* players. Some newer discs have an added region code enhancement (RCE) function that checks to see whether the player is configured for multiple or all regions and then, if it is, refuses to play. Most newer region-free modified players know how to query the disc first to circumvent this check as well.

DVD-ROM drives used in PCs originally did not have RPC in the hardware, placing that responsibility instead on the software used to play DVD video discs on the PC. The player software would usually lock the region code to the first disc that was played and then from that point on, play only discs from that region. Reinstalling the software enabled the region code to be reset, and numerous patches were posted on websites to enable resetting the region code even without reinstalling the software. Because of the relative ease of defeating the region-coding restrictions with DVD-ROM drives, starting on January 1, 2000, all DVD-ROM drives were required to have RPC-II, which embeds the region coding directly into the drive.

RPC-II (or RPC-2) places the region lock in the drive, and not in the playing or MPEG-2 decoding software. You can set the region code in RPC-II drives up to five times total, which basically means you can change it up to four times after the initial setting. Usually, the change can be made using the player software you are using, or you can download region change software from the drive manufacturer. Upon making the fourth change (which is the fifth setting), the drive is locked on the last region set.

Content Scramble System

The Content Scramble System (CSS) provides the main protection for DVD-Video discs. It wasn't until this protection was implemented that the Motion Picture Association of America (MPAA) agreed to release movies in the DVD format, which is the main reason the rollout of DVD had been significantly delayed.

CSS originally was developed by Matsushita (Panasonic) and is used to digitally scramble and encrypt the audio and video data on a DVD-Video disc. Descrambling requires a pair of 40-bit (5-byte) keys (numeric codes). One of the keys is unique to the disc, whereas the other is unique to the video title set (VTS file) being descrambled. The disc and title keys are stored in the lead-in area of the disc in an encrypted form. The CSS scrambling and key writing are carried out during the glass mastering procedure, which is part of the disc manufacturing process.

You can see this encryption in action if you put a DVD disc into a DVD-ROM drive on a PC, copy the files to your hard drive, and then try to view the files. The files are usually called **VTS_xx_yy.VOB** (video object), where **xx** represents the title number and **yy** represents the section number. Typically, all the files for a given movie have the same title number and the movie is spread out among several 1GB or smaller files with different section numbers. These .VOB files contain both the encrypted video and audio streams for the movie interleaved together. Other files with a .IFO extension contain information used by the DVD player to decode the video and audio streams in the .VOB files. If you copy the .VOB and .IFO files onto your hard drive and try to click or play the .VOB files directly, you either see and hear scrambled video and audio or receive an error message about playing copyprotected files.

This encryption is not a problem if you use a CSS-licensed player (either hardware or software) and play the files directly from the DVD disc. All DVD players, whether they are consumer standalone units or

software players on your PC, have their own unique CSS unlock key assigned to them. Every DVD video disc has 400 of these 5-byte keys stamped onto the disc in the lead-in area (which is not usually accessible by programs) on the DVD in encrypted form. The decryption routine in the player uses its unique code to retrieve and unencrypt the disc key, which is then used to retrieve and unencrypt the title keys. CSS is essentially a three-level encryption that originally was thought to be very secure but has proven otherwise.

In October 1999, a 16-year-old Norwegian programmer was able to extract the first key from one of the commercial PC-based players, which allowed him to very easily decrypt disc and title keys. A now famous program called DeCSS was then written that can break the CSS protection on any DVD video title and save unencrypted .VOB files to a hard disk that can be played by any MPEG-2 decoder program. Needless to say, this utility (and others based on it) has been the cause of much concern in the movie industry and has caused many legal battles over the distribution and even links to this code on the Web. Do a search on DeCSS for some interesting legal reading.

As if that weren't enough, in March 2001, two MIT students published an incredibly short (only seven lines long!) and simple program that can unscramble CSS so quickly that a movie can essentially be unscrambled in real-time while it is playing. They wrote and demonstrated the code as part of a twoday seminar they conducted on the controversial Digital Millennium Copyright Act, illustrating how trivial the CSS protection really is.

Because of the failure of CSS, the DVD forum is now actively looking into other means of protection, especially including digital watermarks, which consists essentially of digital noise buried into the data stream, which is supposed to be invisible to normal viewing. Unfortunately, when similar technology was applied to DIVX (the discontinued proprietary DVD standard), these watermarks caused a slight impairment of the image a raindrop or bullet-hole effect could be seen by some in the picture. Watermarks also might require new equipment to play the discs.

Analog Protection System

APS (also called CopyGuard by Macrovision) is an analog protection system developed by Macrovision and is designed to prevent making VCR tapes of DVD-Video discs. APS requires codes to be added to the disc, as well as special modifications in the player. APS starts with the creation or mastering of a DVD, where APS is enabled by setting predefined control codes in the recording. During playback in an APS-enabled (Macrovision-enabled) player, the digital-to-analog converter (DAC) chip inside the player adds the APS signals to the analog output signal being sent to the screen. These additions to the signal are designed so that they are invisible when viewed on a television or monitor but cause copies made on most VCRs to appear distorted. Unfortunately, some TVs or other displays can react to the distortions added to create a less-than-optimum picture.

APS uses two signal modifications called automatic gain control and colorstripe. The automatic gain control process consists of pulses placed in the vertical scan interval of the video signal, which TVs can't detect but which cause dim and noisy pictures, loss of color, loss of video, tearing, and so forth on a VCR. This process has been used since 1985 on many prerecorded video tapes to prevent copying. The colorstripe process modifies colorburst information that is also transparent on television displays but produces lines across the picture when recorded on a VCR.

Note that many older players don't have the licensed Macrovision circuits and simply ignore the code to turn on the APS signal modifications. Also, various image stabilizer, enhancer, or copyguard decoder units are available that can plug in between the player and VCR to remove the APS copyguard signal and allow a perfect recording to be made.

CD/DVD Read-Only Drives and Specifications

When evaluating a CD-ROM or DVD-ROM drive for your PC, you should consider three distinct sets of criteria, as follows:

- The drive's performance specifications
- The interface the drive requires for connection to your PC
- The physical disc-handling system the drive uses

These criteria will affect how fast the drive operates, how it is connected to your system, and how convenient (or inconvenient) it is to use. These same criteria, plus media and speed issues, are also important considerations when selecting a rewritable drive.

Performance Specifications

Many factors in a drive can affect performance, and several specifications are involved. Typical performance figures published by manufacturers are the data transfer rate, the access time, the internal cache or buffers (if any), and the interface the drive uses. The following sections examine these specifications.

CD Data Transfer Rate

The data transfer rate for a CD-ROM or CD-RW drive tells you how quickly the drive can read from the disc and transfer to the host computer. Normally, transfer rates indicate the drive's capability for reading large, sequential streams of data.

Transfer speed is measured two ways. The one most commonly quoted with CD/DVD drives is the "x" speed, which is defined as a multiple of the particular standard base rate. For example, CD-ROM drives transfer at 153.6KBps according to the original standard. Drives that transfer twice that are 2x, 40 times that are 40x, and so on. DVD drives transfer at 1,385KBps at the base rate, whereas drives that are 20 times faster than that are listed as 20x. Note that because almost all faster drives feature CAV, the "x" speed usually indicated is a maximum that is seen only when reading data near the outside (end) of a disc. The speed near the beginning of the disc might be as little as half that, and of course, average speeds are somewhere in the middle.

With today's optical drives supporting multiple disc formats, multiple read and write specifications are given for each form of media a drive supports. Drives that read from and write to CD-R and CD-RW media typically can read and write at speeds between 4x and 40x (CAV).

CD Drive Speed

When a drive seeks out a specific data sector or musical track on the disc, it looks up the address of the data from a table of contents contained in the lead-in area and positions itself near the beginning of this data across the spiral, waiting for the right string of bits to flow past the laser beam.

Because CDs originally were designed to record audio, the speed at which the drive reads the data had to be constant. To maintain this constant flow, CD-ROM data is recorded using a technique called *constant linear velocity (CLV)*. This means that the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 1.3 meters per second. Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at various rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area than when reading the outer track area. The speed of rotation in a 1x drive (1.3 meters per second is considered 1x speed) varies from 540rpm when reading the start (inner part) of the track down to 212rpm when reading the end (outer part) of the track.

In the quest for greater performance, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, one that spins four times faster was called 4x, and so on. This was fine until about the 12x point, where drives were spinning discs at rates from 2,568rpm to 5,959rpm to maintain a constant data rate. At higher speeds than this, it became difficult to build motors that could change speeds (spin up or down) as quickly as necessary when data was read from different parts of the disc. Because of this, most drives rated faster than 12x spin the disc at a fixed rotational, rather than linear speed. This is termed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) remains a constant.

CAV drives are also generally quieter than CLV drives because the motors don't have to try to accelerate or decelerate as quickly. A drive (such as most rewritables) that combines CLV and CAV technologies is referred to as *Partial-CAV* or *P-CAV*. Most writable drives, for example, function in CLV mode when burning the disc and in CAV mode when reading. [Table 11.23](#) compares CLV and CAV.

Table 11.23. CLV Versus CAV Technology Quick Reference

CLV (Constant Linear Velocity)		CAV (Constant Angular Velocity)
Speed of CD rotation	Varies with data position on CDfaster on inner tracks than on outer tracks	Constant

Data transfer rate	Constant	Varies with data position on CDfaster on outer tracks than on inner tracks
Average noise level	Higher	Lower

CD-ROM drives have been available in speeds from 1x up to 52x and beyond. Most nonrewritable drives up to 12x were CLV; most drives from 16x and up are CAV. With CAV drives, the disc spins at a constant speed, so track data moves past the read laser at various speeds, depending on where the data is physically located on the CD (near the inner or outer part of the track). This also means that CAV drives read the data at the outer edge (end) of the disk more quickly than data near the center (beginning). This allows for some misleading advertising. For example, a 12x CLV drive reads data at 1.84MBps no matter where that data is on the disc. On the other hand, a 16x CAV drive reads data at speeds up to 16x (2.46MBps) on the outer part of the disc, but it also reads at a much lower speed of only 6.9x (1.06MBps) when reading the inner part of the disc (that is the part they don't tell you). On average, this would be only 11.5x, or about 1.76MBps. In fact, the average is actually overly optimistic because discs are read from the inside (slower part) out, and an average would relate only to reading completely full discs. The real-world average could be much less than that.

What this all means is that on average the 12x CLV drive would be noticeably faster than the 16x drive, and faster than even a 20x drive! Remember that all advertised speeds on CAV drives are only the maximum transfer speed the drive can achieve, and it can achieve that only when reading the very outer (end) part of the disc.

[Table 11.24](#) contains data showing CD-ROM drive speeds along with transfer rates and other interesting data.

Table 11.24. CD-ROM Drive Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11	Column 12
Advertised CD-ROM Speed (Max. if CAV)	Time to Read 74-Minute CD if CLV	Time to Read 80-Minute CD if CLV	Transfer Rate (Bps) (Max. if CAV)	Actual CD-ROM Speed Minimum if CAV	Minimum Transfer Rate if CAV (Bps)	Average CD-ROM Speed if CAV	Average Transfer Rate if CAV (Bps)	Maximum Linear Speed (mps)	Maximum Linear Speed (mph)	Rotational Speed Min. if CLV Max. if CAV (rpm)	Rotational Speed Max. if CLV (rpm)
1x	74.0	80.0	153,600	0.4x	61,440	0.7x	107,520	1.3	2.9	214	497

52x	1.4	1.5	7,987,200	22.4x	3,440,640	37.2x	5,713,920	67.6	151.2	11,130	25,821
56x	1.3	1.4	8,601,600	24.1x	3,701,760	40.1x	6,151,680	72.8	162.8	11,986	27,808

Each of the columns in [Table 11.24](#) is explained here:

Column 1 indicates the advertised drive speed. This is a constant speed if the drive is CLV (most 12x and lower) or a maximum speed only if CAV.

Columns 2 and 3 indicate how long it would take to read a full disc if the drive was CLV. For CAV drives, those figures would be longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives would be a maximum figure only when reading the end of a disc.

Columns 36 indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it would be even lower) in both "x" and byte-per-second formats.

Columns 78 indicate the maximum linear speeds the drive will attain, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.

Columns 912 indicate the rotational speeds of a drive. The first of those shows how fast the disc spins when reading the start of a disc; this would apply to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc it is reading. The last column shows the maximum rotational speed if the drive were a CLV type. Because most drives over 12x are CAV, those figures are mostly theoretical for the 16x and faster drives.

Vibration problems can cause high-speed drives to drop to lower speeds to enable reliable reading of CD-ROMs. Your CD-ROM can become unbalanced, for example, if you apply a small paper label to its surface to identify the CD or affix its serial number or code for easy reinstallation. For this reason, many of the faster CD and DVD drives come with autobalancing or vibration-control mechanisms to overcome these problems. The only drawback is that if they detect a vibration, they slow down the disc, thereby reducing the transfer rate performance.

A company called Zen Research developed a technology called TrueX in the late 1990s, which used multiple laser beams to achieve constant high transfer rates with lower spin rates. Unfortunately, TrueX drives made by vendors such as Kenwood didn't live up to the promised performance of TrueX technology and suffered from many reliability problems. Zen Research closed in mid-2002, and TrueX drives are no longer sold. Instead of TrueX, most are now moving to Z-CLV (zoned CLV) or P-CAV (partial CAV) designs, which help increase average performance while keeping rotational speeds under control.

DVD Drive Speed

As with CDs, DVDs rotate counterclockwise (as viewed from the reading laser) and typically are recorded at a constant data rate called CLV. Therefore, the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 3.49 meters per second (or 3.84mps on dual-layer discs). Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at varying rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area and more slowly when reading the outer track area. The speed of rotation in a 1x drive (3.49 meters per second is considered 1x speed) varies from 1,515rpm when reading the start (inner part) of the track down to 570rpm when reading the end (outer part) of the track.

Single-speed (1x) DVD-ROM drives provide a data transfer rate of 1.385MBps, which means the data transfer rate from a DVD-ROM at 1x speed is roughly equivalent to a 9x CD-ROM (1x CD-ROM data transfer rate is 153.6KBps, or 0.1536MBps). This does not mean, however, that a 1x DVD drive can read CDs at 9x rates: DVD drives actually spin at a rate that is just under three times faster than a CD-ROM drive of the same speed. So, a 1x DVD drive spins at about the same rotational speed as a 2.7x CD drive. Many DVD drives list two speeds, one for reading DVDs and another for reading CDs. For example, a DVD-ROM drive listed as a 16x/40x would indicate the performance when reading DVDs/CDs, respectively.

As with CDs, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, a drive that spins four times as fast was 4x, and so on. At higher speeds, it became difficult to build motors that could change speeds (spin up or down) as quickly as needed when data was read from different parts of the disc. Because of this, faster DVD drives spin the disc at a fixed rotational, rather than linear speed. This is termed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) remains a constant.

The faster drives are useful primarily for data, not video. Having a faster drive can reduce or eliminate the pause during layer changes when playing a DVD video disc, but having a faster drive has no effect on video quality.

DVD-ROM drives have been available in speeds up to 20x or more, but because virtually all are CAV, they actually achieve the rated transfer speed only when reading the outer part of a disc. [Table 11.25](#) shows the data rates for DVD drives reading DVDs and how that rate compares to a CD-ROM drive.

Table 11.25. DVD Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11	Column 12	Column 13
Advertised DVD-ROM Speed (Max. if CAV)	Time to Read Single Layer DVD if CLV	Time to Read Dual Layer DVD if CLV	Transfer Rate (Bytes/sec) (Max. if CAV)	Actual DVD Speed Minimum if CAV	Minimum Transfer Rate if CAV (Bytes/sec)	Average DVD Speed if CAV	Average Transfer Rate if CAV (Bytes/sec)	Maximum Linear Speed (m/sec)	Maximum Linear Speed (mph)	Single Layer Rot. Speed Min. if CLV Max. if CAV (rpm)	Single Layer Rot. Speed Max. if CLV (rpm)	Usual Transfer Rate When Reading CD-ROMs
1x	56.5	51.4	1,384,615	0.4x	553,846	0.7x	969,231	3.5	7.8	570	1,515	2.7x

Column 1 indicates the advertised drive speed. This is a constant speed if the drive is CLV or a maximum speed only if CAV (most DVD-ROM drives are CAV).

Columns 2 and 3 indicate how long it would take to read a full disc (single- or dual-layer) if the drive were CLV. For CAV drives, those figures are longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives is a maximum figure seen only when reading the end of a disc.

Columns 48 indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it's even lower) in both "x" and byte-per-second formats.

Columns 9 and 10 indicate the maximum linear speeds the drive attains, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.

Columns 11 and 12 indicate the rotational speeds of a drive. The first of those shows how quickly the disc spins when reading the start of a disc. This applies to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc it is being read. The second of those two columns shows the maximum rotational speed if the drive were a CLV type. Because most faster drives are CAV, those figures are mostly theoretical for the faster drives.

Column 13 shows the speed the drive would be rated if it were a CD-ROM drive. This is based on the rotational speed, not the transfer rate. In other words, a 12x DVD drive would perform as a 32x CD-ROM drive when reading CDs. Most DVD drives list their speeds when reading CDs in the specifications. Due to the use of PCAV (Partial CAV) designs, some might have higher CD performances than the table indicates.

Access Time

The access time for a CD or DVD drive is measured the same way as for PC hard disk drives. In other words, the access time is the delay between the drive receiving the command to read and its actual first reading of a bit of data. The time is recorded in milliseconds; a typical manufacturer's rating would be listed as 95ms. This is an average access rate; the true access rate depends entirely on where the data is located on the disc. When the read mechanism is positioned to a portion of the disc nearer to the narrower center, the access rate is faster than when it is positioned at the wider outer perimeter. Access rates quoted by many manufacturers are an average taken by calculating a series of random reads from a disc.

Obviously, a faster (that is, a lower) average access rate is desirable, especially when you rely on the drive to locate and pull up data quickly. Access times for CD and DVD drives have been steadily improving, and the advancements are discussed later in this chapter. Note that these average times are significantly slower than PC hard drives, ranging from 200ms to below 100ms, compared to the 8ms access time of a typical hard disk drive. Most of the speed difference lies in the construction of the drive itself. Hard drives have multiple-read heads that range over a smaller surface area of the medium; CD/DVD drives have only one laser pickup, and it must be capable of accessing the entire range of the disc. In addition, the data on a CD is organized in a single long spiral. When the drive positions its head to read a track, it must estimate the distance into the disc and skip forward or backward to the appropriate point in the spiral. Reading off the outer edge requires a longer access time than the inner segments, unless you have a CAV drive, which spins at a constant rate so the access time to the outer tracks is equal to that of the inner tracks.

Access times have fallen a great deal since the original single-speed drives came out. However, recently a plateau seems to have been reached with most CD/DVD drives hovering right around the 100ms area, with some as low as 80ms. With each increase in data transfer speed, you usually see an improvement in access time as well. But as you can see in [Table 11.26](#), these improvements are much less significant because of the physical limitation of the drive's single-read mechanism design.

Table 11.26. Typical CD-ROM Drive Access Times

Drive Speed	Access Time (ms)
1x	400
2x	300
3x	200
4x	150

6x	150
8x12x	100
16x24x	90
32x52x or greater	85 or less

The times listed here are typical examples for good drives; within each speed category some drives are faster and some are slower. Because of the additional positioning accuracy required and the overall longer track, DVD drives usually report two access speeds—one when reading DVDs and the other when reading CDs. The DVD access times typically run 10ms–20ms slower than when reading CDs.

Buffer/Cache

Most CD/DVD drives include internal buffers or caches of memory installed onboard. These buffers are actual memory chips installed on the drive's circuit board that enable it to stage or store data in larger segments before sending it to the PC. A typical buffer for a CD/DVD drive is 128KB, although drives are available that have either more or less (more is usually better). Recordable CD or DVD drives typically have much larger buffers of 2MB–8MB or more to prevent buffer underrun problems and to smooth writing operations. Generally, faster drives come with more buffer memory to handle the higher transfer rates.

Having buffer or cache memory for the CD/DVD drive offers a number of advantages. Buffers can ensure that the PC receives data at a constant rate; when an application requests data from the drive, the data can be found in files scattered across different segments of the disc. Because the drive has a relatively slow access time, the pauses between data reads can cause a drive to send data to the PC sporadically. You might not notice this in typical text applications, but on a drive with a slower access rate coupled with no data buffering, it is very noticeable and even irritating during the display of video or some audio segments. In addition, a drive's buffer, when under the control of sophisticated software, can read and have ready the disc's table of contents, speeding up the first request for data. A minimum size of 128KB for a built-in buffer or cache is recommended and is standard on many 24x and faster drives. For greater performance, look for drives with 256KB or larger buffers.

CPU Utilization

A once-neglected but very real issue in calculating computer performance is the impact that any piece of hardware or software has on the central processing unit (CPU). This "CPU utilization" factor refers to how much attention the CPU (such as Pentium 4, Athlon 64, and so on) must provide to the hardware or software to help it work. A low CPU utilization percentage score is desirable because the less time a CPU spends on any given hardware or software process, the more time it has for other tasks and thus the greater the performance for your system. On CD-ROM drives, three factors influence CPU utilization: drive speed, drive buffer size, and interface type.

Drive buffer size can influence CPU utilization. For CD-ROM drives with similar performance ratings, the drive with a larger buffer is likely to require less CPU time (lower CPU utilization percentage) than the one with a smaller buffer.

Because drive speed and buffer size are more of a given, the most important factor influencing CPU utilization is the interface type. Traditionally, SCSI-interface CD-ROM drives have had far lower CPU utilization rates than ATAPI drives of similar ratings. One review of 12x drives done several years ago rated CPU utilization for ATAPI CD-ROM drives at 65%–80%, whereas SCSI CD-ROM drives checked in at less than 11%. By using DMA or Ultra-DMA modes with an ATA interface drive, near-SCSI levels of low CPU utilization can be realized. Using DMA or Ultra-DMA modes can cut CPU utilization down to the 10% or lower range, leaving the CPU free to run applications and other functions.

Direct Memory Access and Ultra-DMA

Busmastering ATA controllers use Direct Memory Access (DMA) or Ultra-DMA transfers to improve performance and reduce CPU utilization. Virtually all modern ATA drives support Ultra-DMA. With busmastering, CPU utilization for ATA/ATAPI and SCSI CD-ROM drives is about equal at around 11%. Thus, it's to your benefit to enable DMA access for your CD-ROM drives (and your ATA hard drives, too) if your system permits it.

Most recent ATA/ATAPI CD-ROM drives (12x and above) support DMA or Ultra-DMA transfers, as does Windows 95B and above and most recent Pentium-class or newer motherboards. To determine whether your Win9x, Me, or XP system has this feature enabled, check the System Properties' Device Manager tab and click the + mark next to Hard Disk Controllers. A drive interface capable of handling DMA transfers lists "Bus Master" in the name. Next, check the hard drive and CD-ROM information for your system. You can use the properties sheet for your system's CD-ROM drives under Windows 9x/Me and Windows 2000/XP to find this information; you might need to open the system to determine your hard drive brand and model. Hard disk drives and CD-ROM drives that support MultiWord DMA Mode 2 (16.6MBps), UltraDMA Mode 2 (33MBps), UltraDMA Mode 4 (66MBps), or faster can use DMA transfers. Check your product literature or the manufacturer's website for information.

To enable DMA transfers if your motherboard and drives support it, open the Device Manager and then open the properties sheet for the controller or drive. Click the Settings or Advanced Settings tab, and make sure DMA is enabled if available. Depending on which version of Windows you are using, some have the DMA setting in the controller properties and others have it with the individual drives.

Repeat the same steps to enable DMA transfers for any additional hard drives and ATAPI CD-ROM drives in your computer. Restart your computer after making these changes.

Note

If your system hangs after you enable this feature, you must restart the system in Safe mode and uncheck the DMA box. Because DMA transfers bypass the CPU to achieve greater speed, DMA problems could result in data loss. Make backups first, instead of wishing you had later.

Also, if your drive is a parallel ATA model that supports any of the Ultra-DMA (also called Ultra-ATA) modes, you should be sure to use the 80-conductor-style ATA cables. Also be wary of using cables longer than the 18" limit according to the ATA standard. Using these cables prevents noise and signal distortion that will occur if you try to use a standard 40-conductor cable with the Ultra-DMA modes. Most drives and motherboards refuse to enable Ultra-DMA modes faster than 33MBps if an 80-conductor cable is not detected. Note that these cabling issues affect only parallel ATA drives. If your drives are newer Serial ATA (SATA) models, these cabling issues do not apply.

Drive interfaces that don't mention busmastering either can't perform this speedup or need to have the correct driver installed. In some cases, depending on your Windows version and when your motherboard chipset was made, you must install chipset drivers to enable Windows to properly recognize the chipset and enable DMA modes. Virtually all motherboard chipsets produced since 1995 provide busmaster ATA support. Most of those produced since 1997 also provide UltraDMA support for up to 33MHz (Ultra-ATA/33) or 66MHz (Ultra-ATA/66) speed operation. Still, you should make sure that DMA is enabled to ensure you are benefiting from the performance it offers. Enabling DMA can dramatically improve DVD performance, for example.

Interface

The drive's interface is the physical connection of the drive to the PC's expansion bus. The interface is the data pipeline from the drive to the computer, and its importance shouldn't be minimized. Five types of interfaces are available for attaching a CD-ROM, CD-R, or CD-RW drive to your system:

- ATA/ATAPI (AT Attachment/AT Attachment Packet Interface)
- USB port
- FireWire (IEEE 1394)
- SCSI/ASPI (Small Computer System Interface/Advanced SCSI Programming Interface)
- Parallel port

The following sections examine the ATA, USB, and FireWire interface choices. For more information on SCSI or Parallel, refer to [Chapter 13](#) of *Upgrading and Repairing PCs, 16th Edition*, included in PDF format on this book's DVD.

ATA/ATAPI

The ATA/ATAPI (AT Attachment/AT Attachment Packet Interface) is an extension of the same ATA (AT Attachment) interface most computers use to connect to their hard disk drives. ATA is sometimes also referred to as IDE (Integrated Drive Electronics). ATAPI is an industry-standard ATA interface used for CD/DVD and other drives. ATAPI is a software interface that adapts the SCSI/ASPI commands to the ATA interface. This enables drive manufacturers to take their high-end CD/DVD drive products and quickly adapt them to the ATA interface. This also enables the ATA drives to remain compatible with the extensions that provide the CD/DVD drive with a software interface with DOS. With Windows 9x and later, the CD-ROM extensions are contained in the CD file system (CDFS) VxD (virtual device) driver.

ATA/ATAPI drives are sometimes also called enhanced IDE (EIDE) drives because this is an extension of the original IDE (technically the ATA) interface. In most cases, an ATA drive connects to the system via a second ATA interface connector and channel, leaving the primary one for hard disk drives only. This is preferable because ATA does not share the single channel well and would cause a hard disk drive to wait for CD/DVD commands to complete and vice versa. SCSI does not have this problem because a SCSI host adapter can send commands to different devices without having to wait for each previous command to complete.

The ATA interface represents the most cost-effective and high-performance interface for CD-ROM drives. Most new systems that include a CD and/or DVD drive have it connected through ATA.

Many systems on the market today can use the ATA/ATAPI CD/DVD drive as a bootable device, which allows the vendor to supply a recovery CD that can restore the computer's software to its factory-shipped condition. Later, you'll see how bootable CDs differ from ordinary CDs and how you can use low-cost CD-R/CD-RW drives, along with mastering and imaging software to make your own bootable CDs with your own preferred configuration.

◀◀ See "[An Overview of the IDE Interface](#)," p. [548](#).

▶▶ See "[Bootable CDs and DVDs](#)El Torito," p. [809](#).

USB Interface

Universal Serial Bus (USB) has proven to be extremely flexible and has been used for everything from keyboards and joysticks to CD/DVD drives from several vendors.

USB 1.1 and earlier drives provide read and write transfer rates that match the fastest rates possible with IEEE 1284 parallel ports, with read rates on typical 6x models ranging from 1,145KBps to 1,200KBps. USB 2.0 and later provide a transfer rate up to 60MBps, which is 40 times faster than USB 1.1 and yet is fully backward-compatible.

USB also provides benefits that no parallel port drive can match: for example, hot-swappability, which is the capability to be plugged in or unplugged without removing the power or rebooting the system. Additionally, USB devices are fully Plug and Play, allowing the device to be automatically recognized by the system and the drivers automatically installed.

For Windows 98/Me or Windows 2000/XP systems with USB ports, USB-based CD-RW drives are an excellent solution for backup and archiving of data onto low-cost, durable optical media.

FireWire

In addition, external CD/DVD drives are now available on the market with a FireWire (also called IEEE 1394 or iLink) interface. FireWire is a high-performance external interface designed mainly for video use. It evolved as an Apple standard and is used primarily on Macintosh systems. Because few PCs include FireWire ports as a standard item whereas all PCs include USB, I usually recommend the more universally supported USB for external CD/DVD drives. Make sure any external drives you purchase use the faster USB 2.0 (also known as Hi-Speed USB), which is faster and far more readily available than FireWire versions. FireWire drives can be useful if you work in a two-platform environment (both PCs and Macs). However, because most Macs also support USB (and you can easily add a USB interface to those that don't), if your primary platform is the PC, I'd still recommend USB over FireWire.

If you do want to use a FireWire drive and your system does not include FireWire integrated into the motherboard, you can easily add a FireWire interface card to your PC. Additionally, some video and sound cards are available with FireWire ports as an option.

►► See "[Universal Serial Bus](#)," p. [980](#), and "[IEEE 1394](#)," p. [989](#).

Loading Mechanism

Three distinctly different mechanisms exist for loading a disc into a CD/DVD drive: the tray, caddy, and slot. Each one offers some benefits and features. Which type you select has a major impact on your use of the drive because you interact with this mechanism every time you load a disc.

Some drives on the market allow you to insert more than one disc at a time. Some of these use a special cartridge that you fill with discs, much like multidisc CD changers used in automobiles. Newer models are slot-loading, allowing you to push a button to select which internal cartridge slot you want to load with a CD/DVD. The drive's door opens and you slide in the CD, which the drive mechanism grabs and pulls into place. Typical capacities range from three to six discs or more, and these are available in both SCSI and ATA interfaces.

Tray

Most current SCSI and ATAPI CD/DVD drives use a tray-loading mechanism. This is similar to the mechanism used with a stereo system. Because you don't need to put each disc into a separate caddy, this mechanism is much less expensive overall. However, it also means that you must handle each disc every time you insert or remove it.

Tray loading is less expensive than a caddy system (see the section, "Caddy," later in this chapter) because you don't need a caddy. It is also more convenient, unless you have caddies for all your discs. However, this can make it much more difficult for young children or those who work in harsh environments to use the discs without smudging or damaging them due to excess handling.

The tray loader itself is also subject to damage. The trays can easily break if bumped or if something is dropped on them while they are extended. Also, any contamination you place on the tray or disc is brought right into the drive when the tray is retracted. Tray-loaded drives should not be used in a harsh environment, such as a commercial or an industrial application. Make sure both the tray and the data surface of the disc are clean whenever you use a tray-loading drive.

The tray mechanism also does not hold the disc as securely as the caddy. If you don't have the disc placed in the tray properly when it retracts, the disc or tray can be damaged. Even a slight misalignment can prevent the drive from reading the disc properly, forcing you to open the tray and reset the disc.

Some tray drives can't operate in a vertical (sideways) position because gravity prevents proper loading and operation. Check to see whether the drive tray has retaining clips that grab the hub of the disc or tabs that fold in or flip over from the outside of the tray to retain the disc. If so, you can run the drive in either a horizontal or vertical position.

The main advantage of the tray mechanism over the others is in cost, and that is a big factor. Most drives today use the tray mechanism for handling discs.

Caddy

At one time, the caddy system was used on most high-end CD-ROM drives as well as the early CD-R and DVD-RAM drives. The caddy system requires that you place the disc itself into a special caddy, which is a sealed container with a metal shutter. The caddy has a hinged lid you open to insert the disc, but after that the lid remains shut. When you insert the caddy containing the disc into the drive, the drive opens a metal shutter on the bottom of the caddy, allowing access to the disc by the laser.

When caddy-loaded drives were popular, they were extremely convenient to use if you had a caddy for each drive and extremely inconvenient if you shared a single caddy among all your media. The caddy was inserted into the drive, much the way you would insert a 3 1/2" floppy disk. The caddy protected the CD from scratches, contamination, and careless handling.

The drawbacks to the caddy system included the expense and the inconvenience of having to put the discs into the caddies.

When DVD-RAM was first introduced, the disc had to remain in a caddy because the recordable surface is delicate. Since then, DVD-RAM drives have been made caddy-less, but especially with doublesided discs the information is at risk every time you handle the disc. Because of this fragility, as well as the general incompatibility of DVD-RAM with DVD-ROM, I recommend DVD+RW as the best solution for recordable DVD. No caddy is required with DVD

+RW, and the format is fully two-way compatible with most recent DVD-Video players and DVD-ROM drives.

The caddy-loading system has declined in popularity for CD and DVD drives because of the convenience of the tray. Today only a few of the drives on the market use caddies, and they are generally not for mainstream use. Next-generation optical drives such as Blu-ray DVD might offer some variation on the traditional caddy-loading system, but at this time it's not clear which loading system will become the most popular.

Slot

Some drives now use a slot-loading mechanism, identical to that used in most automotive CD players. This is very convenient because you just slip the disc into the slot, where the mechanism grabs it and draws it inside. Some drives can load several CDs at a time this way, holding them internally inside the drive and switching discs as access is required.

The primary drawback to this type of mechanism is that if a jam occurs, it can be much more difficult to repair because you might have to remove the drive to free the disc. Another drawback is that slot-loading drives usually can't handle the smaller 80mm discs, card-shaped discs, or other modified disc physical formats or shapes.

Other Drive Features

Although drive specifications are of the utmost importance, you should also consider other factors and features when evaluating CD-ROM drives. Besides quality of construction, the following criteria bear scrutiny when making a purchasing decision:

- Drive sealing
- Self-cleaning lenses
- Internal versus external drive

Drive Sealing

Dirt is your CD/DVD drive's biggest enemy. Dust or dirt, when it collects on the lens portion of the mechanism, can cause read errors or severe performance loss. Many manufacturers seal off the lens and internal components from the drive bay in airtight enclosures. Other drives, although not sealed, have double dust doors—one external and one internal—to keep dust from the inside of the drive. All these features help prolong the life of your drive.

Some drives are sealed, which means no air flows through the chamber in which the laser and lens reside. Always look for sealed drives in harsh industrial or commercial environments. In a standard office or home environment, it is probably not worth the extra expense.

Self-Cleaning Lenses

If the laser lens gets dirty, so does your data. The drive will spend a great deal of time seeking and reseeking or will finally give up. Lens-cleaning discs are available, but built-in cleaning mechanisms are now included on virtually all good-quality drives. This might be a feature you'll want to consider, particularly if you work in a less-than-pristine work environment or have trouble keeping your desk clean, let alone your drive laser lens. You can clean the lens manually, but it is generally a delicate operation requiring that you partially disassemble the drive. Also, damaging the lens mechanism by using too much force is pretty easy to do. Because of the risks involved, in most cases I do not recommend the average person disassemble and try to manually clean the laser lens.

Internal Versus External Drives

When deciding whether you want an internal or external drive, think about where and how you're going to use your drive. What about the future expansion of your system? Both types of drives have advantages and disadvantages, such as the following:

- *External enclosure.* These tend to be rugged, portable, and large in comparison to their internal versions. External drives are ideal for sharing a drive with multiple systems or especially with laptops or notebook portable systems. Parallel port drives are very portable and supported on a broad range of machines, but USB drives are a better choice for Windows 98 or later systems that have USB ports. Connect recent drives to the faster USB 2.0 port for best performance.

If you have an IEEE 1394 (FireWire, i.LINK) port and don't have a USB 2.0 port, this port type provides speed comparable to SCSI and USB 2.0 and the hot-swappability of USB. Some optical drives are now equipped with both USB 2.0 and IEEE 1394 ports.

- *Internal enclosure.* Internal drives won't take up any space on your desk. Buy an internal drive if you have a free drive bay and a sufficient power supply and you plan to keep the drive exclusively on one machine. The internal drives are also nice because you can connect the audio connector to your sound card and leave the external audio connectors free for other inputs. Internal drives are typically ATA.

Writable CDs

Although the CD originally was conceived as a read-only device, these days you easily can create your own data and audio CDs. By purchasing CD-R or CD-RW discs and drives, you can record (or burn) your own CDs. This enables you to store large amounts of data at a cost that is lower than most other removable, random-access mediums.

It might surprise newcomers to the world of PCs to see just how far recordable CD technology, performance, and pricing has come. Today you can buy recorders that operate at up to 52x speeds and cost under \$100. You can even purchase Slimline CD drives for laptops. Compare this to the first CD-R recording system on the market in 1988, which cost more than \$50,000 (back then, they used a \$35,000 Yamaha audio recording drive along with thousands of dollars of additional error correction and other circuitry for CD-ROM use), operated at 1x speed only, and was part of a subsystem that was the size of a washing machine! The blank discs also cost about \$100 each a far cry from the 25 cents or less they cost today (if you purchase in bulk and are willing to supply your own jewel cases). With prices that high, the main purpose for CD recording was to produce prototype CDs that could then be replicated via the standard stamping process.

In 1991, Philips introduced the first 2x recorder (the CDD 521), which was about the size of a stereo receiver and cost about \$12,000. Sony in 1992 and then JVC in 1993 followed with their 2x recorders, and the JVC was the first drive that had the half-height 5 1/4" form factor that most desktop system drives still use today. In 1995, Yamaha released the first 4x recorder (the CDR100), which sold for \$5,000. A breakthrough in pricing came in late 1995 when Hewlett-Packard released a 2x recorder (the 4020i, which was actually made for them by Philips) for under \$1,000. This proved to be exactly what the market was waiting for. With a surge in popularity after that, prices rapidly fell to below \$500, and then down to \$200 or less. In 1996, Ricoh introduced the first CD-RW drive.

Compared with either tape or other removable media, using a CD burner is a very cost-effective and easy method for transporting large files or making archival copies. Another benefit of the CD for archiving data is that CDs have a much longer shelf life than tapes or other removable media.

Two main types of recordable CD drives and discs are available, called CD-R (recordable) and CD-RW (rewritable). Because all CD-RW drives can also function as CD-R drives, and the prices of CD-R and RW drives are similar, virtually all drives sold today are CD-RW. Those drives can work with either CD-R or CD-RW discs. In addition, because the CD-RW discs are 1.54 times more expensive than CD-R discs, only half as fast (or less) as CD-R discs, and won't work in all CD audio or CD-ROM drives, people usually write to CD-R media in their CD-RW drives.

Note

Because of differences in reflectivity of the media, older CD and DVD drives can't read CD-RW media. Most newer CD or DVD-ROM drives conform to the MultiRead specification and as such can read CD-RWs. But many older drives are still out there that do not conform. As such, if you are recording something that many people or systems will need to read, CD-R is your best choice for overall compatibility.

CD-R media is a WORM (write once, read many) media, meaning that after you fill a CD-R with data, it is permanently stored and can't be erased. The write-once limitation makes this type of disc less than ideal for system backups or other purposes in which it would be preferable to reuse the same media over and over. However, because of the low cost of CD-R media, you might find that making permanent backups to essentially disposable CD-R discs is as economically feasible as tape or other media.

CD-RW discs can be reused up to 1,000 times, making them suitable for almost any type of data storage task. When first introduced, there were many CD-R-only drives; however, today most recordable CD drives are both CD-R and CD-RW in one. The following sections examine these two standards and how you can use them for your own data storage needs.

CD-R

Once recorded, CD-R discs can be played back or read in any standard CD-ROM drive. CD-R discs are useful for archival storage and creating master CDs, which can be duplicated for distribution within a company.

CD-Rs function using the same principle as standard CD-ROMs, by bouncing laser light off the disc and tracking the changes in reflectivity when pit/land and land/pit boundaries are encountered. The main difference is that instead of being stamped or embossed into plastic as on regular CDs, CD-Rs have images of pits burned onto a raised groove instead. Therefore, the pits are not really raised bumps like on a standard CD, but instead are rendered as dark (burned) areas on the groove that reflect less light. Because the overall reflectivity of pit and land areas remains the same as on a stamped disc, normal CD-ROM or CD audio drives can read CD-Rs exactly as if they were stamped discs.

Part of the recording process with CD-Rs starts before you even insert the disc into the drive. CD-R media is manufactured much like a standard CDa stamper is used to mold a base of polycarbonate plastic. However, instead of stamping pits and lands, the stamper imprints a spiral groove (called a *pre-groove*), into the disc. From the perspective of the reading (and writing) laser underneath the disc, this groove is seen as a raised spiral ridge and not a depression.

The pre-groove (or ridge) is not perfectly straight; instead it has a slight wobble. The amplitude of the wobble is generally very small compared to the track pitch (spacing). The groove separation is 1.6 microns, but it wobbles only 0.030 microns from side to side. The wobble of a CD-R groove is modulated to carry supplemental information read by the drive. The signal contained in the wobble is called absolute time in pre-groove (ATIP) because it is modulated with time code and other data. The time code is the same minutes:seconds:frame format that will eventually be found in the Q-subcode of the frames after they are written to the disc. The ATIP enables the drive to locate positions on the disc before the frames are actually written. Technically, the wobble signal is frequency shift keyed with a carrier frequency of 22.05KHz and a deviation of 1KHz. The wobble uses changes in frequency to carry information.

To complete the CD-R disc, an organic dye is evenly applied across the disc by a spin-coating process. Next, a gold reflective layer is applied, followed by a protective coat of UV-cured lacquer to protect the gold and dye layers. Gold is used in CD-R discs to get the reflectivity as high as possible, and it was found that the organic dye tends to oxidize aluminum. Then, silk-screen printing is applied on top of the lacquer for identification and further protection. When seen from the underside, the laser used to read (or write) the disc first passes through the clear polycarbonate and the dye layer, hits the gold layer where it is reflected back through the dye layer and the plastic, and finally is picked up by the optical pickup sensor in the drive.

The dye and reflective layer together have the same reflective properties as a *virgin* CD. In other words, a CD reader would read the groove of an unrecorded CD-R disc as one long land. To record on a CD-R disc, a

laser beam of the same wavelength (780nm) as is normally used to read the disc, but with 10 times the power, is used to heat up the dye. The laser is fired in a pulsed fashion at the top of the ridge (groove), heating the layer of organic dye to between 482°F and 572°F (250°300°C). This temperature literally burns the organic dye, causing it to become opaque. When read, this prevents the light from passing through the dye layer to the gold and reflecting back, having the same effect of canceling the laser reflection that an actual raised pit would on a normal stamped CD.

[Figure 11.12](#) shows the CD-R media layers, along with the pre-groove (raised ridge from the laser perspective) with burned pits.

Figure 11.12. CD-R media layers.

The drive reading the disc is fooled into thinking a pit exists, but no actual pit exists there's simply a spot of less-reflective material on the ridge. This use of heat to create the pits in the disc is why the recording process is often referred to as *burning* a CD. When burned, portions of the track change from a reflective to a nonreflective state. This change of state is permanent and can't be undone, which is why CD-R is considered a write-once medium.

CD-R Capacity

All CD-R drives can work with the standard 650MiB (682MB) CD-R media (equal to 74 minutes of recorded music), as well as the higher-capacity 700MiB (737MB) CD-R blanks (equal to 80 minutes of recorded music). The 80-minute discs cost only about 2 cents more than the 74-minute discs, so most would figure why not purchase only the higher-capacity media? Although the extra 55MB of storage can be useful and the cost difference is negligible, the 80-minute discs can actually be harder to read on older CD-ROM and CD-DA drives, especially car audio units. This is because to get the extra 55MB/6 minutes of capacity, the spiral track is wound a little more tightly, making them a bit more difficult to read. If you'll be using the discs for audio or interchange purposes and might be dealing with older equipment, you might want to stick with the 74-minute discs instead. If not, the 80-minute media will be just fine.

Some drives and burning software are capable of overburning, whereby they write data partially into the

lead-out area and essentially extend the data track. This is definitely risky as far as compatibility is concerned. Many drives, especially older ones, fail when reading near the end of an overburned disc. It's best to consider this form of overclocking CDs somewhat experimental. It might be useful for your own purposes if it works with your drives and software, but interchangeability will be problematic.

Some vendors now sell 90-minute (790MiB) and 99-minute (870MiB) media to make overburning easier. Although experiments performed by the Tom's Hardware website (www.tomshardware.com) indicate that most standard CD-RW drives can reliably burn up to 89:59 of music onto the 90-minute media and the CD-R can be played on a wide variety of auto and home electronics players, very few drives can burn a full 90 minutes or more of music (or the equivalent amount of computer data) to this media.

Tip

Wondering whether your drive can handle 90-minute or 99-minute media? Your drive vendor will probably say it can't, but the media compatibility list put together by Jan Distribudora (a major electronics distributor in the Dominican Republic; www.jan.com.do/Archivos/90minCompatibilityBurnersFinal.pdf) can provide a field-tested answer. Check drive compatibility before you buy the longer media.

Note that Roxio (makers of Easy CD Creator and other CD mastering/writing programs) states that trying to write 90-minute or longer media could result in damage to the drive that is writing or reading the media.

CD-R Media Color

There has been some controversy over the years about which colors of CD-R media provide the best performance. [Table 11.27](#) shows the most common color combinations, along with which brands use them and some technical information.

Table 11.27. CD-R Media Color and Its Effect on Recording

Media Color (first color is reflective layer; second is die layer)	Brands	Technical Notes
Gold-gold	Mitsui, Kodak, Maxell, Ricoh	Phthalocyanine dye. Less tolerance for power variations. Has a rate life span of up to 100 years. Might be less likely to work in a wide variety of drives. Invented by Mitsui Toatsu Chemicals. Works best in drives that use a Long Write Strategy (longer laser pulse) to mark media.

Gold-green	Imation (nee 3M), Memorex, Kodak, BASF, TDK	Cyanine dye. More forgiving of disc-write and disc-read variations. Has a rated lifespan of 10 years (older media). Recent media has a rated lifespan of 2050 years (silver/green). Color combination developed by Taiyo Yuden. Used in the development of the original CD-R standards. De facto standard for CD-R industry and was the original color combination used during the development of CD-R technology. Works best in drives that use a Short Write Strategy (shorter laser pulse) to mark media.
Silver-blue	Verbatim, DataLifePlus, HiVal, Maxell, TDK	Process developed by Verbatim. Azo dye. Similar performance to green media plus rated to last up to 100 years. A good choice for long-term archiving.

Some brands are listed with more than one color combination, due to production changes or different product lines. You should check color combinations whenever you purchase a new batch of CD-R media if you've found that particular color combinations work better for you in your applications.

Note

Playstation games originally came on discs that were tinted black for appearance. Soon blank CD-R recordable discs were also available with this same black tint in the polycarbonate. The black tint is purely cosmetic it is invisible to the infrared laser that reads/writes the disc. In other words, "black" CD-R discs are functionally identical to clear discs and can be made using any of the industry-standard dyes in the recording layer. The black tint hides the recording layer visually, so although the laser passes right through it, the black tint prevents you from observing the color of the dye in the recording layer directly.

Ultimately, although the various color combinations have their advantages, the best way to choose a media type is to try a major brand of media in your CD-R/CD-RW drive with both full-disc and small-disc recording jobs and then try the completed CD-R in as wide a range of CD-ROM drive brands and speeds as you can.

The perfect media for you will be the ones that offer you the following:

- High reliability in writing (check your drive model's list of recommended media)
- No dye or reflective surface dropouts (areas where the media won't record properly)
- Durability through normal handling (scratch-resistant coating on media surface)
- Compatibility across the widest range of CD-ROM drives
- Lowest unit cost

If you have problems recording reliably with certain types of media, or if you find that some brands with the same speed rating are much slower than others, contact your drive vendor for a firmware upgrade.

Firmware upgrades can also help your drive recognize new types of faster media from different vendors.

▶▶ See "[Updating the Firmware in a CD-RW or Rewritable DVD Drive](#)," p. [813](#).

Choosing the Best Media

After you determine which media works best for you and your target drives, you might still be faced with a wide variety of choices, including conventional surface, printable surface, unbranded, jewel case, and bulk on spindle. The following list discusses these options:

- *Conventional surface.* Choose this type of media if you want to use a marker to label the CD rather than adding a paper label. This type of CD often has elaborate labeling, including areas to indicate CD title, date created, and other information as well as prominent brand identification. Because of the surface marking, it's not suitable for relabeling unless you use very opaque labels. It's a good choice for internal backups and data storage, though, where labeling is less important.
- *Printable surface.* Choose this type of media if you have a CD printer (a special type of inkjet printer that can print directly onto the face of the CD). Because the brand markings are usually low-contrast or even nonexistent (to allow overprinting), this type also works well with labeling kits such as NEATO and others.
- *Unbranded.* Usually sold in bulk on spindle, these are good choices for economy or use with labeling kits.
- *Jewel case.* Any of the preceding versions can be sold with jewel cases (the same type of case used for CD-ROM software and music CDs). This is a good choice if you plan to distribute the media in a jewel case, but it raises your costs if you plan to distribute or store the media in paper, Tyvek, or plastic sleeves. Hint: Use extra jewel cases to replace your broken jewel cases in your CD software or music collection!
- *Bulk on spindle.* This media generally comes with no sleeves and no cases. It is usually the lowest-priced packaging within any brand of media. This is an excellent choice for mass duplication, or for those who don't use jewel cases for distribution.

CD-R Media Recording Speed Ratings

With CD-R mastering speeds ranging from 1x (now-discontinued first-generation units) up through the latest state-of-the-art 48x52x rates, it's important to check the speed rating (x-rating) of your CD-R media.

Most branded media on the market today is rated to work successfully at up to 32x recording speeds. Some brands indicate this specifically on their packaging, whereas you must check the websites for others to get this information. If your drive is faster than 32x, look for media that supports the maximum speed of your drive and comes from a manufacturer supported by your drive. If necessary, install the latest firmware updates to reach maximum recording speed.

▶▶ See "[Updating the Firmware in a CD-RW or Rewritable DVD Drive](#)," p. [813](#).

Note

The current 52x CD-R recording speed might be the fastest speed ever achieved by CD-RW drives. Many vendors believe that the risk of damage to media and drives at faster spin rates

and the technical difficulties in reliably recording data at higher speeds, plus the rising popularity of rewritable DVD, might make the 52x generation the last generation of CD-RW drives. However, even if you prefer a DVD rewritable drive for making DVDs, you might want a fast CD-RW drive as well. 40x or faster CD-RW drives create CD-Rs much more quickly than many current rewritable DVD drives do.

If speed ratings are unavailable for your media, you might want to restrict your burning to 32x or lower for data. If you are burning audio CDs, you might find that some devices work better with media burned at 8x or lower speeds than with media burned at higher speeds.

Tip

Some drives and mastering software support a setting that automatically determines the best speed to use for burning a CD-R. Software that supports this type of feature analyzes the media and adjusts writing methods and write speed during the write process to ensure the best results. Using this feature with media with an unknown speed rating helps you get a reliable burn no matter what the speed rating of the media is.

CD-RW

Beginning in early 1996, an industry consortium that included Ricoh, Philips, Sony, Yamaha, Hewlett-Packard, and Mitsubishi Chemical Corporation announced the CD-RW format. The design was largely led by Ricoh, and it was the first manufacturer to introduce a CD-RW drive in May 1996. This drive was the MP6200S, which was a 2/2/6 (2x record, 2x rewrite, 6x read) rated unit. At the same time, the Orange Book Part III was published, which officially defined the CD-RW standard.

Since that time, CD-RW drives have pretty much replaced CD-R-only drives in the market today, mainly because CD-RW drives are fully backward-compatible with CD-R drives and can read and write the same CD-R media with the same capabilities. So, a CD-RW drive can also function as a CD-R drive. CD-RW discs can be burned or written to just like CD-Rs; the main difference is that they can be erased and reburned again and again. They are very useful for prototyping a disc that will then be duplicated in less expensive CD-R or even stamped CDs for distribution. They can be rewritten at least 1,000 times or more. Additionally, with packet-writing software, they can even be treated like giant floppy disks, where you can simply drag and drop or copy and delete files at will. Although CD-RW discs are about twice as expensive as CD-R media, CD-RWs are still far cheaper than optical cartridges and other removable formats. This makes CD-RW a viable technology for system backups, file archiving, and virtually any other data storage task.

Note

The CD-RW format originally was referred to as CD-Erasable, or CD-E.

Four main differences exist between CD-RW and CD-R media. In a nutshell, CD-RW discs are

- Rewritable

- More expensive
- Slower when writing
- Less reflective

Besides the CD-RW media being rewritable and costing a bit more, they also are writable at about half (or less) the speed of CD-R discs. This is because the laser needs more time to operate on a particular spot on the disk when writing. They also have a lower reflectivity, which limits readability in older drives. Many older standard CD-ROM and CD-R drives can't read CD-RWs. However, MultiRead capability is now found in virtually all CD-ROM drives of 24x speed or above, enabling them to read CD-RWs without problems. In general, CD-DA drives especially the car audio players seem to have the most difficulty reading CD-RWs. So, for music recording or compatibility with older drives, you should probably stick to CD-R media. Look for the MultiRead logo on a CD-ROM drive, which indicates the capability to read CD-RW. When you shop for a new standalone CD player, look for those that specify the capability to read CD-R/CD-RW media.

CD-RW drives and media use a phase change process to create the illusion of pits on the disc. As with CD-R media, the disc starts out with the same polycarbonate base with a wobbled pre-groove molded in, which contains ATIP information. Then, on top of the base a special dielectric (insulating) layer is spin-coated, followed by the phase change recording layer, another dielectric layer, an aluminum reflective layer, and finally a UV-cured lacquer protective layer (and optional screen printing). The dielectric layers above and below the recording layer are designed to insulate the polycarbonate and reflective layers from the intense heat used during the phase-change process.

[Figure 11.13](#) shows the CD-RW media layers, along with the pre-groove (raised ridge from the laser perspective) with burned pits in the phase change layer.

Instead of burning an organic dye as with CD-R, the recording layer in a CD-RW disc is made up of a phase-change alloy consisting of silver, indium, antimony, and tellurium (Ag-In-Sb-Te). The reflective part of the recording layer is an aluminum alloy, the same as used in normal stamped discs. As a result, the recording side of CD-RW media looks like a mirror with a slight blue tint. The read/write laser works from the underside of the disk, where the groove again appears like a ridge, and the recording is made in the phase-

change layer on top of this ridge. The recording layer of Ag-In-Sb-Te alloy normally has a polycrystalline structure that is about 20% reflective. When data is written to a CD-RW disc, the laser in the drive alternates between two power settings, called P-write and P-erase. The higher power setting (P-write) is used to heat the material in the recording layer to a temperature between 500°C and 700°C (932°1,292° F), causing it to melt. In a liquid state the molecules of the material flow freely, losing their polycrystalline structure and taking what is called an *amorphous* (random) state. When the material then solidifies in this amorphous state, it is only about 5% reflective. When being read, these areas lower in reflectivity simulate the pits on a stamped CD-ROM disc.

That would be all to the story if CD-RW discs were read-only, but because they can be rewritten, there must be a way to bring the material back to a polycrystalline state. This is done by setting the laser to the lower-power P-erase mode. This heats the active material to approximately 200°C (392°F), which is well below the liquid melting point but high enough to soften the material. When the material is softened and allowed to cool more slowly, the molecules realign from a 5% reflective amorphous state back to a 20% reflective polycrystalline state. These higher reflective areas simulate the lands on a stamped CD-ROM disc.

Note that despite the name of the P-erase laser power setting, the disc is not ever explicitly "erased." Instead, CD-RW uses a recording technique called *direct overwrite*, in which a spot doesn't have to be erased to be rewritten; it is simply rewritten. In other words, when data is recorded the laser remains on and pulses between the P-write and P-erase power levels to create amorphous and polycrystalline areas of low and high reflectivity, regardless of which state the areas were in prior. It is similar in many ways to writing data on a magnetic disk that also uses direct overwrite. Every sector already has data patterns, so when you write data, all you are really doing is writing new patterns. Sectors are never really erased; they are merely overwritten. The media in CD-RW discs is designed to be written and rewritten up to 1,000 times.

CD-RW Speeds

The original Orange Book Part III Volume 1 (CD-RW specification) allowed for CD-RW writing at up to 4x speeds. New developments in the media and drives were required to support speeds higher than that. So in May 2000, Part III Volume 2 was published, defining CD-RW recording at speeds from 4x to 10x. This revision of the CD-RW standard is called High-Speed Rewritable, and both the discs and drives capable of CD-RW speeds higher than 4x will indicate this via the logos printed on them. Part III Volume 3 was published in September 2002 and defines Ultra-Speed drives, which are CD-RW drives capable of recording speeds 8x24x.

Because of the differences in High-Speed and UltraSpeed media, High-Speed media can be used only in High-Speed and Ultra-Speed drives; Ultra-Speed Media can be used only in Ultra-Speed drives. Both High-Speed and Ultra-Speed drives can use standard 2x4x media, enabling them to interchange data with computers that have standard-speed CD-RW drives. Thus, choosing the wrong media to interchange with another system can prevent the other system from reading the media. If you don't know which speed of CD-RW media the target computer supports, I recommend you either use standard 2x4x media or create a CD-R.

Because of differences in the UDF standards used by the packet-writing software that drags and drops files to CD-RW drives, the need to install a UDF reader on systems with CD-ROM drives, and the incapability of older CD-ROM and first-generation DVD-ROM drives to read CD-RW media, I recommend using CD-RW media for personal backups and data transfer between your own computers. However, when you send CD data to another user, CD-R is universally readable, making it a better choice.

MultiRead Specifications

The original Red and Yellow Book CD standards specified that on a CD the lands should have a minimum reflectance value of about 70% and the pits should have a maximum reflectance of about 28%. Therefore, the area of a disc that represents a land should reflect back no less than 70% of the laser light directed at it, whereas the pits should reflect no more than 28%. In the early 1980s when these standards were developed, the photodetector diodes used in the drives were relatively insensitive, and these minimum and maximum reflectance requirements were deliberately designed to create enough brightness and contrast between pits and lands to accommodate them.

On a CD-RW disc, the reflectance of a land is approximately 20% (plus or minus 5%) and the reflectivity of a pit is only 5% obviously well below the original requirements. Fortunately, it was found that by the addition of a relatively simple AGC circuit, the ratio of amplification in the detector circuitry can be changed dynamically to allow for reading the lower-reflective CD-RW discs. Thus, although CD-ROM drives were not initially capable of reading CD-RW discs, modifying the existing designs to enable them to do so wasn't difficult. Where you might encounter problems reading CD-RW discs is with CD audio drives, especially older ones. Because CD-RW first came out in 1996 (and took a year or more to become popular), most CD-ROM drives manufactured in 1997 or earlier have problems reading CD-RW discs. Reflectivity is also a problem on DVD-Video and DVD-ROM drives because they use a different frequency laser, they actually have more trouble reading CD-R discs than CD-RWs.

DVDs also have some compatibility problems. With DVD, the problem isn't just simple reflectivity as it is an inherent incompatibility with the laser wavelength used for DVD versus CD-R and RW. The problem in this case stems from the dyes used in the recording layer of CD-R and RW discs, which are very sensitive to the wavelength of light used to read them. At the proper CD laser wavelength of 780nm, they are very reflective, but at other wavelengths, the reflectivity falls off markedly. Normally, CD-ROM drives use a 780nm (infrared) laser to read the data, whereas DVD drives use a shorter wavelength 650nm (red) laser. Although the shorter wavelength laser works well for reading commercial CD-ROM discs because the aluminum reflective layer they use is equally reflective at the shorter DVD laser wavelength, it doesn't work well at all for reading CD-R or RW discs.

Fortunately, a solution was first introduced by Sony and then similarly by all the other DVD drive manufacturers. This solution consists of a dual-laser pickup that incorporates both a 650nm (DVD) and 780nm (CD) laser. Some of these used two discrete pickup units with separate optics mounted to the same assembly, but they eventually changed to dual-laser units that use the same optics for both, making the pickup smaller and less expensive. Because most manufacturers wanted to make a variety of drives including cheaper ones without the dual-laser pickup a standard needed to be created so that someone purchasing a drive would know the drive's capabilities.

So, how can you tell whether your drive is compatible with CD-R and RW discs? To demonstrate the compatibility of a particular drive, OSTA created industry standard tests and logos that would guarantee specific levels of compatibility. These are called the MultiRead specifications. Currently there are two levels, as follows:

- *MultiRead*. For CD-ROM drives
- *MultiRead2*. For DVD-ROM drives

In addition, a similar MultiPlay standard exists that is for consumer DVD-Video and CD-DA devices.

[Table 11.28](#) shows the two levels of MultiRead capability that can be assigned to drives and the types of media guaranteed to be readable in such drives.

Table 11.28. MultiRead and MultiRead2 Compatibility

Standards for CD/DVD Drives

Media	MultiRead	MultiRead2	Media	MultiRead	MultiRead2
CD-DA	X	X	DVD-ROM		X
CD-ROM	X	X	DVD-Video		X
CD-R	X	X	DVD-Audio		X
CD-RW	X	X	DVD-RAM		X

X = Compatible; drive will read this media

= Incompatible; drive won't read

Note that MultiRead also indicates that the drive is capable of reading discs written in Packet Writing mode because this mode is now being used more commonly with both CD-R and RW media.

To determine whether your drive meets either of these standards, merely look for the MultiRead or MultiRead2 logo on the drive, as shown in [Figure 11.14](#).

Figure 11.14. MultiRead and MultiRead2 logos.

The presence of these logos guarantees that particular level of compatibility. If you are purchasing a CD-ROM or DVD-ROM drive and want to be able to read recordable or rewritable discs, be sure to look for the MultiRead or MultiRead2 logo on your drive. Especially in the case of DVD drives, MultiRead2 versions are generally more expensive because of the extra cost of the dual-mode laser pickup required. Virtually all DVD-ROM drives for computers have the dual pickup mechanism, enabling them to properly read CD-R or CD-RW discs. However, most DVD video players used in entertainment systems do not have the dual pickups.

You can obtain the latest versions of the MultiRead specification (revision 1.11, October 23, 1997) and MultiRead 2 specification (revision 1.0, December 6, 1999) from the OSTA website.

How to Reliably Record CDs

With typical burn times for full CD-Rs ranging from under 3 minutes (40x or faster speeds) to as long as 80 minutes (1x), it is frustrating when a buffer underrun or some other problem forces you to rewrite your CD-RW disc, or worse yet, turn your CD-R media to a coasteran unusable disc that must be discarded.

Five major factors influence your ability to create a working CD-R: interface type, drive buffer size, the location and condition of the data you want to record to CD-R, the recording speed, and whether the computer is performing other tasks while trying to create the CD-R.

To improve the odds of getting reliable CD-R/RW creation, look for drives with the following:

- *A large data buffer (2MB or larger), or better yet some form of buffer underrun protection.* The data buffer in the drive holds information read from the original data source, so that if a pause in data reading occurs, there's less of a possibility of a buffer underrun until the on-drive buffer runs empty. A larger buffer minimizes the chance of "running out of data." Newer drives with buffer underrun protection virtually eliminate this problem, no matter what size buffer is in the drive.
- *Support for UDMA operating modes.* As you've already seen, UDMA modes transfer data more quickly and with less CPU intervention than earlier versions of ATA. To use this feature, you'll also need a motherboard with a busmastering UDMA interface with the appropriate drivers installed.

Tip

Also, if you have problems with reliable CD-R creation at the drive's maximum speed, try using a lower speed (24x instead of 48x, for example). Your mastering job will take twice as long, but it's better to create a working CD-R slowly than ruin a blank quickly.

An alternative approach is to use packet-writing software to create your CD-R. All late-model CD-R/CD-RW drives support packet writing, which allows drag-and-drop copying of individual files to the CD-R/RW rather than transferring all the files at once as with normal mastering software. This "a little at a time" approach means that less data must be handled in each write and can make the difference between success and failure. If your drive supports this feature, it probably includes packet-writing software in the package. Note that although packet-written CDs can be read with Windows 9x/Me and NT/2000/XP, they can't be read with Windows 3.1 and MS-DOS because these operating systems don't have drivers available that support packet-written CDs. Note that some CD-mastering software supports packet-writing to CD-Rs, but others don't. For example, the DirectCD program included with Roxio Easy CD Creator can packet-write to both CD-R and CD-RW media and close CD-R media for reading on any drive, but Nero Burning ROM's InCD packet-writing software doesn't support CD-R.

Note

Imaging software such as PowerQuest DriveImage works from a DOS prompt but uses packet-writing to copy data to CD-R media. Because a backup created with DriveImage must be restored from a DOS prompt in some versions of the program, DriveImage includes a special DOS-compatible packet-writing driver that is loaded during its startup process.

If your CD-R/RW drive is SCSI based, be sure you have the correct type of SCSI interface card and cables. Although many drive vendors take the uncertainty out of this issue by supplying an appropriate card and cables, others don't.

If you must buy your own SCSI card for your recorder, follow these tips:

- *Forget about ISA cards.* Many new motherboards no longer include ISA slots, and even if they do, the performance of the ISA bus presents a bottleneck that will seriously inhibit drive performance.
- *PCI or Cardbus SCSI works well.* As discussed in [Chapter 15](#), "I/O Interfaces from Serial and Parallel to IEEE 1394 and USB," PCI's 32-bit data bus and 33MHz typical performance is far faster than ISA's 16-bit data bus and 8.33MHz typical performance. Cardbus is PCI for notebooks, so the same benefits apply there as well.
- *Make sure the SCSI card is rated for CD-RW/CD-R use.* The SCSI host adapters that are designed for use with and are sometimes bundled with low-performance devices such as scanners and Zip drives are not adequate for use with a CD-R or CD-RW drive.

Tip

Several manufacturers, including Adaptec, Promise Tech, SIIG, Tekram, and Advansys, offer high-performance PCI SCSI cards.

Buffer Underruns

Whenever a drive writes data to a CD-R/RW disc in either Disk at Once or Track at Once mode, it writes to the spiral track on the CD, alternating on and off to etch the pattern into the raw media. Because the drive can't easily realign where it starts and stops writing like a hard drive can, after it starts writing it must typically continue until it's finished with the track or disc. Otherwise, the recording (and disc if it is a CD-R) will be ruined. This means that the CD recording software, in combination with your system hardware, must be capable of delivering a consistent stream of data to the drive while it's writing. To aid in this effort, the software uses a buffer that it creates on your hard disk to temporarily store the data as it is being sent to the drive.

If the system is incapable of delivering data at a rate sufficient to keep the drive happy, you receive a buffer underrun message and the recording attempt fails. The buffer underrun message indicates that the drive had to abort recording because it ran out of data in its buffer to write to the CD. For many years, this was the biggest problem people had when recording to CD-R/RW media. And for many years, the best way to prevent buffer underruns was to either slow down the writing speeds or have a large buffer in the recording drive, as well as to use the fastest interface and reading drive as possible. Nobody wants to write at lower speeds (otherwise, why buy a fast drive?), so buffer sizes grew as did the interface speeds. Still, it was possible to get a buffer underrun if, for example, you tried browsing web pages or doing other work while burning a disc.

Buffer Underrun Protection

Sanyo was the first to develop a technology that eliminates buffer underruns once and for all. It calls the technology BURN-Proof ("BURN" stands for "buffer underrun"), which sounds a little confusing (some people thought it prevented any writing on discs), but in practice it has proven to be excellent.

After Sanyo, several other companies have developed similar and compatible technology with various names. Including Sanyo's, the most common you'll see are

- BURN-Proof, from Sanyo
- JustLink, from Ricoh
- Waste-Proof, from Yamaha
- Safeburn, from Yamaha

- Superlink, from Mediatek

You will see these technologies on many vendors' drives because most developers of this technology license it to various drive makers.

Buffer underrun protection technology involves having a special chipset in the drive that monitors the drive buffer. When it anticipates that a buffer underrun might occur (the buffer is running low on data), it temporarily suspends the recording until more data fills the buffer. When the buffer is sufficiently restocked, the drive then locates exactly where the recording left off earlier and restarts recording again immediately after that position.

According to the Orange Book specification, gaps between data in a CD recording must not be more than 100 milliseconds in length. The buffer underrun technology can restart the recording with a gap of 4045 milliseconds or less from where it left off, which is well within the specification. These small gaps are easily compensated for by the error correction built into the recording, so no data is lost.

Note that it is important that the drive incorporate buffer underrun technology, but the recording software must support it as well for everything to work properly. Fortunately, all the popular CD recording programs on the market now support this technology.

If your drive incorporates buffer underrun protection, you can multitask do other things while burning CDs without fear of producing a bad recording.

Producing Error-Free Recordings

If you have an older drive that doesn't feature buffer underrun protection, follow these recommendations to help ensure error-free recordings and prevent buffer underruns:

- *Whenever possible, move all the data you want to put onto a CD-R to a fast local hard drive.* If you can't do this, avoid using the following sources for data: floppy drives, parallel port connected storage drives, and slower CD-ROM drives (especially 8x or slower). These locations for data usually can't feed data quickly enough to maintain data flow to the recording drive.
- *Before you master the CD-R, check your hard disk or data source for errors (the Windows 9x/Me Scandisk or Windows 2000/XP error-checking program can often be used for this).* Also try defragmenting the drive. This ensures that disk errors or file fragmentation, both of which slow down disk access, won't be a factor in program or data search and retrieval.
- *Avoid trying to burn from active files or zero-byte files (often used for temporary storage).* If you must burn these files to make an archival copy of your current system configuration, use a program such as Norton Ghost or PowerQuest Drive Image. These programs create a single compressed file from your drive's contents. Then, burn the disc using the resulting compressed file.
- *Turn off power management for your hard disk and other peripherals.* In Windows you normally do this through the Power icon in the Control Panel.
- *Make sure your temporary drive has at least twice the empty space of your finished CD.* Your CD's estimated space requirements are shown during the mastering process with programs such as Roxio Easy CD-Creator or NERO Burning ROM. Thus, if you're creating a CD with 500MB of data, your temporary drive should have at least 1GB of empty space.
- *With Windows 9x/Me, you'll improve disk caching by adjusting the typical role of the computer from workstation to server in the Performance tab of the System Properties dialog box.* Note that this change works correctly with Windows 95B and 95C (OSR 2.x) and Windows 98/Me, but the Registry keys are incorrect in Windows 95 original retail and OSR1 (95A) versions. Check Microsoft's website for the correct Registry key settings for Windows 95/95A, back up and edit the Registry, and restart the computer before making this change with those versions.

- *If your original data is coming from a variety of sources, consider using the Create Disk Image option found in most CD mastering software.* This feature creates an image file on your hard drive that contains all the files you want to put onto a CD. Then, use Create CD from Disk Image to actually master the CD from that information.
- *If you're uncertain of success, why waste a CD-R blank?* Use a CD-RW instead, which usually is written at a slower speed, or use the "test-then-create" option found in most recording software that does a simulated burn of the CD before the actual creation. After the simulation, you're warned of any problems before the actual process begins. This is not always foolproof, but it can help.
- *Small files are harder to use in mastering a CD than large ones because of the excessive drive tracking necessary to find them and load them.* You might want to use the Packet Writing mode instead if your drive and software support it.
- *Keep your drives clean and free from dust.* Use a cleaning CD if necessary. Dirty drives cause dataread errors or data-write errors if your recording drive is the dirty one.
- *Don't multitask.* If you run another program during the mastering process, the computer is forced to perform time-slicing, which causes it to start a process, switch away from it to start the next process, switch back to the first process, and so forth. This switching process could cause the recording drive to run out of data because it isn't receiving data in a steady stream. Forget about surfing the Internet, playing Solitaire, or creating a label for your new CD during the burning process if you want reliable mastering on a drive that doesn't feature buffer underrun protection.

If you're still having buffer underrun problems despite taking all the precautions listed here, try dropping down a speed. Go to the next lower speed and see how you do. Using a lower speed than the drive is rated for can be frustrating, but it's preferable to wasting time creating unusable discs.

As a final note, I have also seen problems with burning CDs caused by inadequate power supplies. An inadequate or overtaxed power supply can cause myriad recording problems (including buffer underruns). I've seen cases in which the system seemed to be normal in most respects, but there were tremendous problems recording CDs, from buffer underruns to power calibration errors. After upgrading the power supply with a high-quality, high-output unit, the problems all but disappeared. I've said it many times, but the power supply is the foundation of a PC, and in general it is the most failure-prone or problematic piece of hardware in the system. See [Chapter 19](#), "Power Supplies," for more information on power supplies, including recommended suppliers for upgraded units.

Recording Software

Another difficulty with CD-R/RW devices is that they usually require special software to write them. Although most cartridge drives and other removable media mount as standard devices in the system and can be accessed exactly like a hard drive, the CD-R/RW drives and most types of rewritable DVD drives use special CD-ROM/DVD burning software to write to the disc (DVD-RAM drives don't require special software to write to DVD-RAM media). This software handles the differences between how data is stored on a CD and how it is stored on a hard drive. As you learned earlier, there are several CD-ROM standards for storing information. The CD-ROM-burning software arranges the data into one of these formats so a CD-ROM reader can read the CD later. Windows XP and later include CD writing software built in; operating systems prior to that required that you purchase and install third-party CD writing software. Still, most have found that the popular third-party CD writing applications such as CD-Creator (Roxio) or Nero Burning ROM (Ahead Software) are far more powerful and easier to use than what Windows includes or what is packaged with some drives.

At one time, CD recording technology required that you have what amounted to a replica of the CD on a local hard drive. In fact, some software packages even required a separate, dedicated disk partition for this purpose. You would copy all the files to the appropriate place on the hard drive, creating the directory structure for the CD, and then the software would create an exact replica of every sector for the proposed CD-ROM including every file, all the directory information, and the volume information and copy it to the CD-

R drive. The result was that you had to have about 1.5GB of storage to burn a single CD ($650\text{MB}/\text{CD} \times 2 = 1.3\text{GB} + \text{overhead} = 1.5\text{GB}$). This is no longer a requirement because most software supports virtual images. You select the files and directories you want to write to the CD from your hard drive and create a virtual directory structure for the CD-ROM in the software. This means you can select files from different directories on different hard drives, or even files from network or other CD-ROM drives, and combine them any way you want on the CD-R. This works well provided the drives have adequate speed and your drive has a large buffer or features buffer underrun protection. If you have problems, follow the advice given earlier to overcome slow data sources.

The software assembles the directory information, burns it onto the CD, opens each file on the CD, and copies the data directly from the original source. This generally works well, but you must be aware of the access times for the media you select as data sources. If, for example, you select directories from a slow hard drive or from a busy network, the software might not be capable of reading the data quickly enough to maintain a consistent stream to the recorder. In drives lacking buffer underrun protection, this causes the write to fail, resulting in a wasted disc.

Don't Forget the Software!

If you have persistent problems with making CDs, your recording software or drive might be to blame. Check the vendor's website for tips and software updates. Some drives offer software-upgradable firmware similar to the motherboard's flash BIOS; if so, be sure your drive has the latest firmware available. Also make sure that your recording software is up-to-date and compatible with your drive and your drive's firmware revision.

Each of the major CD-R/CD-RW drive vendors provides extensive technical notes to help you achieve reliable recordings. You can also find helpful information on SCSI adapter vendors' websites and the websites of the media vendors.

▶▶ See "[Updating the Firmware in a CD-RW or Rewritable DVD Drive](#)," p. 813.

Digital Audio Extraction

All CD-ROM drives can *play* Red Bookformatted CD-DA discs, but not all CD-ROM drives can *read* CD-DA discs. The difference sounds subtle, but it is actually quite dramatic. If you enjoy music and want to use your PC to manage your music collection, the ability to read the audio data digitally is an important function for your CD (and DVD) drives because it enables you to much more easily and accurately store, manipulate, and eventually write back out audio tracks.

CD-ROM drives installed in PCs can play audio discs. The playing function is simple: Using a CD or Media player application (such as the one included with Windows), you can insert a CD-DA disc into a CD-ROM drive and play it just as you could with a standard audio CD player. While playing, the analog sound waveform is sent over a thin stereo cable (usually referred to as the CD audio cable) connected between your CD-ROM drive and the sound card in your PC. The same analog waveform usually is also sent to the headphone jack on the front of the drive (or sound card). Your sound card then amplifies the analog signal

so you can hear it through the speakers plugged into your sound card or via headphones plugged into the front of the drive (or the sound card).

That is just fine if all you want to do is play discs, but if you ever want to record one of the songs on your hard disk, you will run into some problems. To transfer the song to your hard drive, you would have to play the song as you did normally and simultaneously use a sound recorder application, such as the Sound Recorder supplied with Windows 95 and later (similar recording software is also typically supplied with your sound card), to redigitize the audio waveform for storage as a .WAV file on the PC. This means the sound goes from digital as originally stored on the disc to analog in the CD-ROM drive and back to digital in your sound card, with the resulting digital file being only an approximation of the original digital data. Another drawback is that this procedure runs only at 1x speedhardly an ideal situation!

It would be much better if you could read the original digital data directly off the disc. That was not possible with older CD-ROM drives, but newer drives can do what is called *digital audio extraction (DAE)*. In this process they read the digital audio sectors directly and, rather than decode them into analog signals, pass each 2,352-byte sector of raw (error-corrected) digital audio data directly to the PC's processor via the drive interface cable (ATA, SCSI, USB, or FireWire). Therefore, no digital-to-analog conversion (and back) occurs, and you essentially get the audio data exactly as it was originally recorded on the CD (within the limits of the CD-DA error-correction standards). You would have essentially extracted the exact digital audio data from the disc onto your PC.

Another term for digital audio extraction is *ripping*, so named because you can "rip" the raw audio data from the drive at full drive read speed, rather than the normal 1x speed at which you listen to audio discs. Actually, most drives can't perform DAE at their full rated speeds. Although some are faster (or slower) than others, most perform DAE at speeds from about one-quarter to about one-half of their rated read speed. So, you might be able to extract audio data at speeds only up to 20x on a 40x rated drive. However, that is still quite a bit better than at 1x as it would be on drives that can't do DAE (not to mention skipping the conversion to analog and back to digital with the resultant loss of information).

Virtually all newer CD/DVD drives can perform digital audio extraction on music discs. How fast or accurately they do this varies from model to model. One might think any extraction (digital copy) of a given track (song) should be the same because it is a digital copy of the original; however, that is not always the case. The CD-DA format was designed to play music, not to transfer data with 100% accuracy. Errors beyond the capability of the CIRC in the CD-DA format cause the firmware in the drive to interpolate or approximate the data. In addition, time-based problems due to clock inaccuracies can occur in the drive, causing it to get slightly out of step when reading the frames in the sector (this is referred to as *jitter*). Differences in the internal software (firmware) in the drive and differences in the drivers used are other problems that can occur.

Positioning can also be a problem because the CD-DA format was designed to stream (play continuously) and not to read individual sectors. CD-ROM sectors are 2,352 bytes long, and these bytes are further divided into 2,048 bytes of data plus 304 bytes of synchronization, header, and additional ECC information to control positioning and allow for error-free reads. No such synchronization, header, or extra ECC information exists for audio sectors; instead, all 2,352 bytes are used for pure audio data. To address an audio sector, the Q subcode information is used instead (see the section "Subcodes," earlier in this chapter). Most audio players position to within only 75 sectors (1 second) using the Q subcode information. CD-ROM drives that can perform digital audio extraction are usually much more accurate than that, but because of how the subcode works (as well as the crossinterleaved way audio data is stored), designing a drive that can position every time to the precise audio sector that starts the track can be difficult.

All of this conspires to cause inaccuracies or slight differences in multiple extractions of the same track (song). Perfect extractions are possible, but making perfect extractions is difficult to achieve for many reasons. For example, even a slight amount of dirt or scratches on the disc has a great effect on the quality

of your extractions, so be sure the discs are clean. As a test of your drive's capability to perform DAE, try extracting the same track (song) multiple times from a new, clean, scratch-free disc, using a different filename for each extraction. Then, bring up a command prompt and use the **FC** (file compare) command to compare the different files to each other. If they compare exactly, you have a combination of hardware and software that can do perfect or near-perfect extractions.

If you intend to do a lot of extracting, you should ask around to see what hardware and software others are using for this purpose. As a general rule, SCSI drives work better than ATA, but some ATA drives are just as good as the better SCSI drives. Plextor is well known for drives that are excellent when it comes to digital audio extraction, and I've always had good luck with Toshiba drives.

The bottom line is that DAE enables you to extract audio data tracks directly to your PC as WAV files. Once on the PC, you can play the WAV files as is or convert them to other (usually more compressed) formats, such as MP3 (MPEG-1/2 Layer III) for use with the MP3 audio players on the market.

Note

Because the WAV files extracted match the high 44.1KHz sampling rate used on the CD, you have 176,400 bytes per second of sound information, which means 1 minute of music consumes nearly 10.6MB worth of space on your hard drive! MP3 compression can reduce that by a factor of 6 or more, with little to no perceptible loss in quality.

You can also use a CD-R/RW drive that can perform DAE to make copies of audio CDs (for backup purposes only) or to compile several songs into your own greatest hits collections that you can use to burn your own custom audio CDs.

"For Music Use Only" CD-R/RW Discs

According to the Audio Home Recording Act of 1992, consumer CD recordable drives *and media* sold specifically for recording music are required to have specific safeguards against copying discs, mainly SCMS. That means these recorders can make digital copies only from original prerecorded discs. You can copy a copy, but in that case, the data being recorded goes from digital to analog and back to digital on the second copy, resulting in a generational loss of quality.

The media for these recorders must be special as well. They work only with special discs labeled "For Music Use," "For Audio," or "For Consumer." These carry the standard Compact Disk Digital Audio Recordable logo that most are familiar with, but below that, as part of the logo, is an added line that says "For Consumer." These discs feature a special track prerecorded onto the disc, which the consumer music recorders look for. Built into the price of the AHRA-compliant media is a royalty for the music industry that this track protects. The media costs about 20%30% more than what regular CD-R/RW media costs. If you try to use standard non-AHRA-compliant CD-R/RW discs in these drives, the drive refuses to recognize the disc. These music devices also refuse to copy CD-ROM or data discs.

Note that this does not apply to the CD-R/RW drive you have installed or attached to your PC. It does not have to be AHRA compliant, nor does it need to use AHRA-compliant "For Music Use" media, even if you are copying or recording music discs. Additionally, you can make digital copies of copiesthe SCMS does not apply, either. The bottom line is that you do not have to purchase AHRA-compliant discs for the CD-R/RW drives in your PC. If you do purchase such discs, despite the "For Music Use Only" designation, AHRA-compliant discs can be used in your CD-R/RW drives just as regular CD-R/RW discs can be used for storing

data. The extra information indicating AHRA compliance is simply ignored.

CD Copy Protection

Worries about the public copying of software and music CDs has prompted the development of copy protection techniques that attempt to make these discs uncopyable. There are different methods of protecting software CDs versus music CDs, but the end result is the same: You are prevented from making normal copies, or the copies don't work properly. In the case of music CDs, the copy protection can be quite obtrusive, adding noise to the recording, and in extreme cases preventing the disc from even playing in a PC drive.

Several copy protection schemes are available for CD-DA (digital audio) discs, ranging from the simple to sophisticated. The most popular protection scheme for digital audio discs is called SafeAudio by Macrovision. Macrovision won't explain exactly how SafeAudio works, but it purchased the technology from a company called TTR Technologies and patents filed by TTR describe the scheme in detail. According to the patents, the disc is deliberately recorded with grossly erroneous values (bursts of noise) in both the audio data and the codes, which would typically be used to correct these errors.

When reading the disc, the normal error correction scheme fails, leaving small gaps in the music. When this happens on a standard audio CD player, the gaps are automatically bridged by circuitry or code in the player, which looks at the audio data on either side of the gap and interpolates (guesses) the missing values. The CD drive in a PC can do the same thing, so the interpolation occurs only when playing CDs in an audio player mode. However, the drive in a PC does not perform this same interpolation when "ripping" the data—that is, copying it directly to a hard drive, another CD, or some other medium. In that case the unbridged gaps are heard as extremely loud clicks, pops, and noise. Both TTR and Macrovision claim that the interpolation that occurs when playing a SafeAudio disc is not discernable to the human ear, but many audio experts disagree. To an audiophile, the addition of any distortion or noise to the audio signal is unconscionable.

Even more rigorous protection can be added that can render the audio disc unplayable on a PC and even cause problems on audio players. Of course, the final problem is that you can't make legal backups of your music—something that is allowed by law.

For software (rather than audio), several protection schemes are used, although most are similar to one another. Again the most popular is by Macrovision, but for CD-ROMs it is called SafeDisc. As with SafeAudio, Macrovision purchased the technology from another company; in this case it was a company called C-Dilla.

SafeDisc works by first encrypting all the software code on the disc and then adding a routine to the code that looks for a unique authentication signature (called a *watermark*) which would have been added to the disc during the mastering process. When executed, the authentication code attempts to read the watermark on the disc. If the watermark is present, the main program code is unencrypted and executed. But if the watermark is not present, the program does not run. Because the watermark does not conform to the normal structures written to a CD, most CD burners can't duplicate it.

The authentication process basically requires that the original CD be present in the drive whenever the program is run. This, however, can be set up so that the original disc is required only during program installation, or it can be checked anytime the program is run, even if run from a hard disk. The latter is quite inconvenient because it requires you to have the original CD with you at all times to run the program.

To circumvent this type of protection, people have developed software that can fool the authentication code into believing the watermark is present. Some software even strips the authentication code from the

software completely. Others have found ways to copy the watermark such that it would appear on any copies of the original CD. As with other forms of copy protection, it has been easily defeated and represents more of a nuisance to the legitimate user rather than to the thief.

Recordable DVD Standards

The history of recordable DVD drives is a troubled one. It dates back to April 1997, when the DVD Forum announced specifications for rewritable DVD, DVD-RAM, and DVD-R. Later, it added DVD-RW to the mix. Dissatisfied with these standards, the industry leaders in optical recording and drives formed their own group called the DVD+RW Alliance and created another standard DVD+R and DVD+RW.

In a war that brings back unhappy memories of the VHS/Beta struggle of the 1980s, as well as the problems in bringing DVD video to light, the computer and movie industries are locked in a struggle to see which enhancements to the basic DVD standard will win out. [Table 11.29](#) compares the competing recordable DVD standards, and [Table 11.30](#) breaks down the compatibilities between the drives and media.

Table 11.29. Recordable DVD Standards

Format	Introduced	Capacity	Compatibility
DVD-RAM	July '97	Up to 4.7GB per side	Incompatible with existing DVD drives unless they support the MultiRead2 standard
DVD-R/RW	July '97/Nov. '99	4.7GB per side	Readable by many existing DVD recorders/drives
DVD+R/RW	Mar. '01/May '01	4.7GB per side	Readable by most existing DVD recorders/drives, with enhancements for video and data recording

As you can see from looking at both the horizontal rows and vertical columns of [Table 11.30](#), the following factors are worth noting:

- Of the single-format drives, DVD+R/RW drives are the most compatible with other media from a read standpoint.
- Increasing numbers of vendors are shipping multifORMAT drives to solve the persistent issues of drive/media compatibility.

Table 11.30. DVD Drive and Media Compatibility

Media (Discs)

Drives	CD-ROM	CD-R	CD-RW	DVD Drive	DVD-ROM	DVD-R	DVD-RAM	DVD-RW	DVD+RW	DVD+R
DVD-Video Player	R	?	?	R		R	?	R	R	R
DVD-ROM Drive	R	R	R	R	R	R	?	R	R ^[1]	R
DVD-R Drive	R	R/W	R/W	R	R	R/W		R	R	R
DVD-RAM Drive	R	R	R	R	R	R ^[6]	R/W	R	R ^[1]	R
DVD-RW Drive	R	R/W	R/W	R	R	R/W		R/W	R	R
DVD+R/RW Drive	R	R/W	R/W	R	R	R	R ^[3]	R	R/W	R/W ^[2]
DVD-Multi Drive ^[4]	R	R/W	R/W	R	R	R	R/W	R/W	R ^[1]	R
DVD±R/RW Drive	R	R/W	R/W	R	R	R/W	R ^[5]	R/W	R/W	R/W

R = Read.

W = Write.

= Will not read or write.

? = MultiRead/MultiPlay drives will read.

^[1] = Might require media's compatibility bit be changed to alternate (Type 2).

^[6] = Some of these drives can also write to DVD-R media.

^[3] = Read compatibility with DVD-RAM varies by drive; check documentation for details.

^[2] = Some first-generation DVD+RW drives will not write DVD+R discs; see your drive manufacturer for an update or trade-in.

^[4] = DVD Forum specification for drives that are compatible with all DVD Forum standards (DVD+R/RW is not a DVD Forum standard).

^[5] = Some of these drives can also write to DVD-RAM media.

DVD+R/RW offers low drive and media prices, provides the highest compatibility with existing formats, and has features that make it the most ideal for both video recording and data storage in PCs.

DVD-RAM

DVD-RAM is the rewritable DVD standard endorsed by Panasonic, Hitachi, and Toshiba; it is part of the DVD Forum's list of supported standards. DVD-RAM uses a phase-change technology similar to that of CD-RW. Unfortunately, DVD-RAM discs can't be read by most standard DVD-ROM drives because of differences in both reflectivity of the media and the data format. (DVD-R, by comparison, is backward compatible with DVD-ROM.) DVD-ROM drives that can read DVD-RAM discs began to come on the market in early 1999 and follow the MultiRead2 specification. DVD-ROM drives and DVD-Video players labeled as MultiRead2 compliant are capable of reading DVD-RAM discs. See the section "MultiRead Specifications," earlier in this chapter, for more information.

The first DVD-RAM drives were introduced in spring 1998 and had a capacity of 2.6GB (single-sided) or 5.2GB (double-sided). DVD-RAM Version 2 discs with 4.7GB arrived in late 1999, and double-sided 9.4GB discs arrived in 2000. DVD-RAM drives typically read DVD-Video, DVD-ROM, and CD media. The current installed base of DVD-ROM drives and DVD-Video players can't read DVD-RAM media; most DVD+R/RW and DVD-R/RW drives can't read DVD-RAM media. To improve compatibility with other formats, many recent DVD-RAM drives can also write to DVD-R media, and the DVD Forum has developed a DVD Multi specification for drives that can read/write DVD-RAM, DVD-R, and DVD-RW media.

DVD-RAM uses what is called the wobbled land and groove recording method, which records signals on both the lands (the areas between grooves) and inside the grooves that are preformed on the disc. The tracks wobble, which provides clock data for the drive. Special sector header pits are prepressed into the disc during the manufacturing process as well. See [Figure 11.15](#), which shows the wobbled tracks (lands and grooves) with data recorded both on the lands and in the grooves. This is unlike CD-R or CD-RW, in which data is recorded on the groove only.

Figure 11.15. DVD-RAM wobbled land and groove recording.

The disc is recorded using phase-change recording, in which data is written by selectively heating spots in the grooves or on the lands with a high-powered laser. The DVD-RAM drive write laser transforms the film from a crystalline to an amorphous state by heating a spot, which is then rendered less reflective than the remaining crystalline portions. The signal is read as the difference of the laser reflection rate between the crystalline and amorphous states. The modulation and error correction codes are the same as for DVD-Video and DVD-ROM, ensuring compatibility with other DVD formats. For rewriting, a lower-powered laser reheats the spot to a lower temperature, where it recrystallizes.

Disc cartridges or caddies originally were required for both single- and double-sided discs but have now been made optional for single-sided discs. Double-sided discs must remain inside the caddy at all times for protection; however, single-sided discs can be taken out of the cartridge if necessary.

DVD-RAM specifications are shown in [Table 11.31](#).

Table 11.31. DVD-RAM Specifications

Storage capacity	2.6GB single-sided; 5.2GB double sided
Disc diameter	80mm120mm
Disc thickness	1.2mm (0.6mmx2: bonded structure)
Recording method	Phase change
Laser wavelength	650nm
Data bit length	0.410.43 microns
Recording track pitch	0.74 microns
Track format	Wobbled land and groove

DVD-R

DVD-R is a write-once medium very similar to CD-R, which was originally created by Pioneer and released by the DVD Forum in July 1997. DVD-R discs can be played on standard DVD-ROM drives. Some recent DVD-RAM drives can also write to DVD-R media.

DVD-R has a single-sided storage capacity of 4.7GBabout seven times that of a CD-Rand double that for a double-sided disc. These discs use an organic dye recording layer that allows for a low material cost, similar to CD-R.

To enable positioning accuracy, DVD-R uses a wobbled groove recording, in which special grooved tracks are pre-engraved on the disc during the manufacturing process. Data is recorded within the grooves only. The grooved tracks wobble slightly right and left, and the frequency of the wobble contains clock data for the drive to read, as well as clock data for the drive. The grooves are spaced more closely together than with DVD-RAM, but data is recorded only in the grooves and not on the lands (see [Figure 11.16](#)).

Figure 11.16. DVD-R wobbled groove recording.

[Table 11.32](#) has the basic specifications for DVD-R drives.

Table 11.32. DVD-R Specifications

Storage capacity	4.7GB single-sided; 9.4GB double-sided
Disc diameter	80mm120mm
Disc thickness	1.2mm (0.6mmx2: bonded structure)
Recording method	Organic dye layer recording method
Laser wavelength	635nm (recording); 635/650nm (playback)
Data bit length	0.293 microns
Recording track pitch	0.80 microns
Track format	Wobbled groove

DVD-RW

The DVD Forum introduced DVD-RW in November 1999. Created and endorsed originally by Pioneer, DVD-RW is basically an extension to DVD-R just as CD-RW is an extension to CD-R. DVD-RW uses a phase-

change technology and is somewhat more compatible with standard DVD-ROM drives than DVD-RAM. Drives based on this technology began shipping in late 1999, but early models achieved only moderate popularity because Pioneer was the only source for the drives and because of limitations in their performance.

Currently, DVD-RW drives are available in 1x DVD-RW/2x DVD-R and the newer 2x DVD-RW/4x DVD-R models. 2x/4x drives have several advantages over older drives, including these:

- *Quick formatting.* 1x/2x drives require that the entire DVD-RW disc be formatted before the media can be used, a process that can take about an hour. 2x/4x drives can use DVD-RW media in a few seconds after inserting, formatting the media in the background as necessary. This is similar to the way in which DVD+RW drives work.
- *Quick grow.* Instead of erasing the media to add files, as with 1x/2x DVD-RW drives, 2x/4x DVD-RW drives can unfinalize the media and add more files without deleting existing files.
- *Quick finalizing.* 2x/4x DVD-RW drives close media containing small amounts of data (under 1GB) more quickly than 1x/2x drives.

However, DVD-RW drives still don't support lossless linking, Mount Rainier, or selective deletion of filesall of which are major features of DVD+RW.

DVD-RW is currently supported by most major makers of CD/DVD-burning software (including Ahead's Nero, Roxio's Easy Media Creator, and others) and by several drive manufacturers.

DVD+RW

DVD+RW, also called DVD Phase Change Rewritable, is rapidly becoming the premier DVD recordable standard because it is the least expensive, easiest to use, and most compatible with existing formats. It was developed and is supported by Philips, Sony, Hewlett-Packard, Mitsubishi Chemical (MCC/Verbatim), Ricoh, Yamaha, and Thomson, who are all part of an industry standard group called the DVD+RW Alliance (www.dvdrw.com). Microsoft joined the alliance in February 2003. DVD+RW is also supported by major DVD/CD creation software vendors and many drive vendors, including HP, Philips, Ricoh, and many remarketers of OEM drive mechanisms. Although DVD-RW has increased in popularity with the advent of faster and easier burning times, DVD+RW is still the most popular rewritable DVD format.

[Table 11.33](#) lists the basic specifications for DVD+RW drives.

Table 11.33. DVD+RW Specifications

Storage capacity	4.7GB single-sided; 9.4GB double-sided (future product)
Disc diameter	120mm
Disc thickness	1.2mm (0.6mmx2: bonded structure)
Recording method	Phase change
Laser wavelength	650nm (recording/playback)
Data bit length	0.4 microns

Recording track pitch 0.74 microns

Track format	Wobbled groove
--------------	----------------

Note that DVD+R, the recordable version of DVD+RW, was actually introduced *after* DVD+RW. This is the opposite of DVD-RW, which grew out of DVD-R. One of the major reasons for the development of DVD+R was to provide a lower-cost method for permanent data archiving with DVD+RW drives, and another was because of compatibility issues with DVD-ROM and DVD video players being incapable of reading media created with DVD+RW drives. However, most standard DVD-ROM drives or DVD players can read both DVD+R and DVD+RW media without problems. See the section "DVD+RW Compatibility Mode," later in this chapter, for details.

The basic structure of a DVD+RW or DVD+R disc resembles that of a DVD-R disc with data written in the grooves only (refer to [Figure 11.16](#)), but the groove is wobbled at a frequency different from that used by DVD-R/RW or DVD-RAM. The DVD+R/RW groove also contains positioning information. These differences mean that DVD+R/RW media offers more accurate positioning for lossless linking, but DVD+R/RW drives can't write to other types of DVD rewritable media.

Although some first-generation DVD+RW drives worked only with rewritable media, all current and future DVD+RW drives are designed to work with both DVD+R (writable) and DVD+RW (rewritable) media. The +R discs can be written only once and are less expensive than the +RW discs.

Some of the features of DVD+RW includes are as follows:

- Single-sided discs (4.7GB).
- Double-sided discs (9.4GB).
- Up to 4 hours video recording (single-sided discs).
- Up to 8 hours video recording (double-sided discs).
- Bare discs no caddy required.
- 650nm laser (same as DVD-Video).
- Constant linear data density.
- CLV and CAV recording.
- Write speeds 1x4x and higher (depending on the drive).
- DVD-Video data rates.
- UDF (Universal Disc Format) file system.
- Defect management integral to the drive.
- Quick formatting.
- Uses same eight to sixteen modulation and error correcting codes as DVD-ROM.
- Sequential and random recording.
- Lossless linking (multiple recording sessions don't waste space).
- Spiral groove with radial wobble.
- After recording, all physical parameters comply with the DVD-ROM specification.

DVD+RW technology is very similar to CD-RW, and DVD+RW drives can read DVD-ROMs and all CD formats, including CD-R and CD-RW.

With DVD+RW, the writing process can be suspended and continued without a loss of space linking the recording sessions together. This increases efficiency in random writing and video applications.

This "lossless linking" also enables the selective replacement of any individual 32KB block of data (the minimum recording unit) with a new block, accurately positioning with a space of 1 micron. To enable this

high accuracy for placement of data on the track, the pre-groove is wobbled at a higher frequency. The timing and addressing information read from the groove is very accurate.

The quick formatting feature means you can pop a DVD+R or DVD+RW blank into the drive and almost instantly begin writing to it. The actual formatting is carried out in the background ahead of where any writing will occur.

DVD+RW is also designed to work with existing DVD video players, DVD+RW-compatible video recorders such as those made by Philips and Yamaha, and DVD-ROM drives. However, because of the wide variance in equipment, DVD+RW tends to work better in newer equipment rather than in older equipment, particularly set-top players. As with DVD-RW, you might prefer to use writable (DVD+R) media to improve the odds of compatibility with older drives and players whose compatibility with DVD+RW is unknown.

DVD+RW is the format I prefer and recommend, and I expect that in the long run it will be the one preferred by most users. However, if you need to work with both DVD+R/RW and DVD-R/RW media because of device compatibility, I recommend one of the DVD±R/RW multifORMAT drives from Sony, NEC, and other vendors. I do not recommend DVD-RAM because it is not supported by set-top players or by most other types of DVD drives.

DVD+RW Compatibility Mode

When DVD+RW drives were introduced in 2001, some users of DVD-ROM and standalone DVD players were unable to read DVD+RW media, even though others were able to do so. The first drives to support DVD+R (writable) media (which works with a wider range of older drives) was not introduced until mid-2002, so this was a significant problem.

The most common reason for this problem turned out to be the contents of the Book Type Field located in the lead-in section of every DVD disc. Some drives require that this field indicate that the media is a DVD-ROM before they can read it. However, by default, DVD+RW drives write DVD+RW as the type into this field when DVD+RW media is used.

The following are two possible solutions:

- Upgrade the firmware in the DVD+RW recorder so it writes compatible information into the Book Type Field automatically
- Use a compatibility utility to change the contents of the Book Type Field for a particular DVD+RW disc as necessary

▶▶ See "[Updating the Firmware in a CD-RW or Rewritable DVD Drive](#)," p. [813](#).

In some cases, the manufacturer of the DVD+RW or DVD+R/RW drive provides a utility as well as a firmware download to perform this task for you. For example, HP includes a compatibility utility with the software provided for the HP DVD200 series and offers it as a download along with updated firmware for the DVD100i drive. Mode 1 (DVD+RW compatibility bits) is the default with these drives, whereas Mode 2 writes DVD-ROM compatibility bits to DVD+RW media (HP drives mark all DVD+R media as DVD-ROM).

Multiformat Rewritable Drives

Because of the fragmented nature of the rewritable DVD marketplace, there are two new categories of drives that provide for wider read/write media compatibility:

- DVD Multi
- DVD±R/RW

DVD Multi is a specification developed by the DVD Forum for drives and players that are compatible with all DVD Forum standards, including DVD-R/RW, DVD-RAM, DVD-ROM, DVD-Video, and eventually DVD Audio (DVD+R/RW are not DVD Forum specifications and are not supported). The original version of DVD Multi was published in February 2001; the current version, version 1.01, was approved by the DVD Forum and published in December 2001. The first DVD Multi products for computers reached the market in early 2003. [Figure 11.17](#) compares the DVD Multi logos to the DVD+RW and other DVD forum logos.

Figure 11.17. The DVD-R/RAM, DVD-RW, and DVD+RW logos (top left to right), compared to new DVD Multi logos in vertical (lower left) and horizontal (lower right) variations (lower right).

DVD±R/RW, unlike DVD Multi, is not a specification. Instead, it is used to indicate drives that work with both DVD+R/RW and DVD-R/RW media (DVD-RAM is not typically supported by these drives). Such drives usually carry both the DVD-RW and DVD+RW logos shown in [Figure 11.17](#). Thus, DVD±R/RW drives are designed to handle the most common formats supported by the DVD Forum and the DVD+RW Alliance.

DVD Multi drives are a good choice for users who have been using DVD-RAM drives but want to enjoy a wider degree of compatibility with the rest of the DVD Forum world. However, if you need to work with the most common types of DVD rewritable media, DVD±R/RW is a better choice. Because of the need to support different read/write technologies, DVD±R/RW drives are more expensive than DVD-R/RW or DVD+R/RW drives.

CD/DVD Drive and Software Installation and Support

CD and DVD drives are installed and configured in the same way as any other drive with the same interface. For details, see the appropriate section:

- For ATA/IDE drives, see [Chapter 7](#), "The ATA/IDE Interface," and [Chapter 12](#), "Physical Drive Installation and Configuration."
- For IEEE 1394a and USB drives, see [Chapter 15](#), "I/O Interfaces from Serial and Parallel to IEEE 1394 and USB."

After you've physically installed the drive, you're ready for the last step installing the drivers and other CD-ROM/DVD-ROM software. As usual, this process can be simple with a PnP operating system such as Windows 9x or later. In that case the drivers for Windows will automatically be installed. Things are different, however, if you need to access the drive after booting from a floppy, such as when installing an operating system, running diagnostics, or running DOS.

Booting from a Floppy Disk with CD/DVD Drive Support

You might need to boot from a floppy drive on a modern PC for many reasons. One reason is to install an operating system on a newly built system or one with a new or unformatted hard drive. In that case, because the system cannot boot from the hard drive, it must boot from a CD or floppy instead.

For a CD or DVD drive to function in a floppy (or CD) boot environment, several drivers might be necessary:

- *An ATAPI host adapter driver (not needed for SCSI drives).* This driver is included with your motherboard, or you can use the generic ATAPI drivers found on Windows 98 and later startup disks.
- *SCSI adapter drivers (not needed for ATAPI drives).* Most SCSI cards include these drivers, or you can use the generic versions included on Windows 98 and later startup disks.
- *MSCDEX.* Microsoft CD Extensions, which is included with DOS 6.0 and later. It is also built into Windows 95 and later as the CDFS VxD.

If you need to start a PC from a bootable floppy, the floppy must contain not only a bootable OS, but also the previously mentioned drivers; otherwise, the CD-ROM will be inaccessible.

Generic ATAPI and SCSI drivers can be found on the Windows 98 and newer startup disks. Rather than create custom **CONFIG.SYS** and **AUTOEXEC.BAT** files, the best advice I can give is to merely boot from a Windows 98 or Me startup floppy because each time you boot from these, the proper drivers load and autodetect the CD/DVD drives, after which the drives are accessible. You can generate a Windows 98/Me startup disk on any system running Windows 98 or Me. If you don't have access to a Windows 98 or Me system, you can download an equivalent bootable floppy from www.bootdisk.com.

After you boot from a Win98/Me floppy, you see a menu that asks whether you want to boot with or without CD-ROM (and DVD) support. If you select yes, after the floppy finishes loading, you should be able to read any discs in the CD or DVD drives.

One possible, and useful, task with this capability is to install any version of Windows in a situation where the installation CD is not bootable (such as with most versions of Windows 9x/Me) or where the system is older than 1998 and cannot boot from a CD. In such a case, all you need to install any version of Windows is the Windows CD and your bootable Windows 98/Me startup floppy. In addition, the fact that the startup floppy is from Windows 98 or Me does not matter; you can install *any* Windows OS using that floppy.

For example, to install Windows 9x/Me onto a system, you could do the following:

1.

Boot from the Windows 98/Me startup floppy, and then select Start Computer with CD-ROM support from the menu. Wait for the **A:** prompt to appear.

2.

Insert the operating system CD you want to install (Windows 95, 98, or Me) into the CD/DVD drive.

3.

Type **D: SETUP** at the **A:** prompt and press Enter. Make sure you substitute the drive letter of your CD/DVD drive for the **D:**.

4.

The SETUP program will run from the CD and begin the operating system installation. Merely follow the prompts as necessary to complete the install.

To install Windows NT, 2000, or XP onto a system, do the following:

1.

Boot from the Windows 98/Me startup floppy and select Start Computer with CD-ROM Support from the menu. Wait for the **A:** prompt to appear.

2.

Insert the operating system CD you want to install (Windows NT, 2000, or XP) into the CD/DVD drive.

3.

Type **D: \i 386\WINNT** at the **A:** prompt and press Enter. Make sure you substitute the drive letter of your CD/DVD drive for the **D:**.

4.

The WINNT program will run from the CD and begin the operating system installation. Merely follow the prompts as necessary to complete the install.

Another useful function you can perform with a Windows 98/Me startup floppy is to format a hard drive larger than 32GiB with FAT32 for use with Windows 2000 or XP. The Format program in Windows 2000 and XP is intentionally restricted by Microsoft from formatting volumes larger than 32GiB even though Windows 2000 and XP support FAT32 volumes up to 2TiB in size. In most cases it is recommended to use NTFS on Windows 2000 or XP systems, but if you are creating a dual-boot environment in which you want to run other operating systems that do not support NTFS, FAT32 is the best choice. The restriction on the Windows 2000/XP format command is a nuisance in such a situation, but the only way around it is to use the format from 98/Me.

Although I've often used a Windows 98/Me startup floppy to install Windows XP, Microsoft does have official XP startup floppies available for downloading from its website. The file is an executable file that creates the startup floppies. To locate this file, visit the Microsoft Knowledge Base at support.microsoft.com and search for article number 310994.

Using a CD-ROM or DVD-ROM drive that conforms to the ATAPI specification under Windows does not require you to do anything. All the driver support for these drives is built into Windows 9x and later

versions, including the ATAPI driver and the CDFS VxD driver.

If you are running a SCSI CD-ROM drive under Windows, you may still need the ASPI driver that goes with your drive. The ASPI driver for your drive usually comes from the drive manufacturer and is included with the drive in most cases. However, by arrangement with hardware manufacturers, Windows typically includes the ASPI driver for most SCSI host adapters and also automatically runs the CDFS VxD virtual device driver. In some rare cases, you might have to install an updated driver that you have obtained from the manufacturer.

When you install a PnP SCSI host adapter in a Windows system, simply booting the computer should cause the operating system to detect, identify, and install drivers for the new device. When the driver for the host adapter is active, the system should detect the SCSI devices connected to the adapter and again load the appropriate drivers automatically.

For DOS users, merely use the Windows 98 or Me startup disk, which includes the necessary DOS SCSI and CD-ROM drivers that support most SCSI cards and CD/DVD drives on the market.

To learn more about the process of preparing to use a CD/DVD drive from a DOS prompt, see "DOS ATAPI CD-ROM Device Driver" in the Technical Reference portion of the disc packaged with this book.

Bootable CDs and DVDsEI Torito

If your system BIOS is a version dated from 1998 or later, most likely it has "EI Torito" support, which means it supports booting from a bootable CD or DVD. The EI Torito name comes from the Phoenix/IBM Bootable CD-ROM Format Specification, which was actually named after the EI Torito restaurant located near the Phoenix Software offices where the two engineers who developed the standard ate lunch. What EI Torito means for the PC is the capability to boot from CDs or DVDs, which opens up several new possibilities, including creating bootable CD/DVD rescue discs, booting from newer OS discs when installing to new systems, creating bootable diagnostics and test CDs, and more.

To create a bootable CD, ideally you need a CD/DVD burning application that allows the creation of bootable discs. Additionally, in some cases you need a bootable floppy that contains the drivers to support your CD drive in DOS mode (sometimes called real-mode drivers). The best source for these drivers (if needed) is a Windows 98 or Me startup floppy, which can be generated by any Windows 98 or Me system. Windows 98/Me startup disks can be used because these have the DOS-level CD-ROM support already configured and installed. If you don't have access to such a system to generate the disk, you can download one from www.bootdisk.com.

Before creating the bootable CD/DVD, test your boot floppy (with CD-ROM drivers) by first booting to the floppy. Then, with a CD or DVD containing files in the CD/DVD drive, see whether you can change to the CD/DVD drive and read a directory of the files (try the **D I R** command). The CD/DVD usually is the next drive letter after your last hard drive letter. For example, if your last hard drive letter is C: , the CD/DVD will be D: .

If you can display a directory listing of the CD/DVD after booting from the floppy, your drivers are properly loaded.

To create a bootable CD or DVD, simply follow the directions included with your CD/DVD burning application. Programs such as CD/DVD Creator by Roxio and Nero Burning ROM by Ahead Software make the creation of bootable discs a relatively easy procedure.

Creating a Rescue CD

Several programs on the market today allow you to make a compressed image file of the contents of any drive. These programs, such as the Ghost program sold by Symantec or PowerQuest's Drive Image, enable you to lock in the condition of any drive as of a particular time.

This enables you to create an image file of your system when it's working and use the image-restore feature to reset your system when it fails.

The perfect place to store a compressed image file is on a CD-R. At a minimum, your rescue disk should contain the compressed image file (a 737MB, 80-minute CD-R/RW could contain the equivalent of a nearly 1.5GB drive's normal contents if the maximum compression option is used). It's also desirable to place a copy of the image-restore program on the CD. Mastering this type of rescue CD is done exactly the same as a conventional CD mastering process. To use the rescue CD, you must boot your system with drivers that allow the CD-ROM drive to work, run the restore program to read the data from the CD, and overwrite the drive's existing contents.

If you're looking for a single-CD solution to rescuing your system, one that won't require you to lug around a bootable floppy disk, you can burn a rescue CD that is bootable all by itself.

Making a Bootable CD/DVD for Emergencies

A little-known capability to PC users is that they can create their own versions of what is standard with more and more new computers: a bootable CD/DVD that can be used to start up a system and restore it to a previously saved state.

The minimum requirements for a bootable CD/DVD include

- *A system supporting the El Torito standard in which the CD/DVD can be designated as a boot drive.* Check your BIOS under Advanced Setup or similar options. Recent and current BIOS code supplied by AMI, Award Software, and Phoenix Technologies typically support El Torito, meaning the CD/DVD can be assigned as a bootable device.
- *A CD/DVD burner and media.*
- *Recording software that allows creation of a bootable CD.* Most modern CD recording software, such as NERO Burning ROM or Roxio CD/DVD Creator, support creating bootable CD/DVDs. If your current CD/DVD-recording software lacks this option, you must upgrade to something that does.
- *A floppy disk containing your operating system boot files.*

ATAPI Drives Are Bootable

Most ATAPI drives connected to a motherboard ATA interface can be used as bootable devices if the BIOS permits it. If your CD-ROM is connected to a sound card, this procedure won't work. If your CD/DVD is connected to a SCSI interface, you'll need a SCSI interface with a BIOS chip that permits booting as well as a bootable disc. Check your BIOS Setup for a page on which boot devices are listed to see whether yours supports a CD/DVD drive as a bootable device.

Because the procedures can vary for different burning software, you should follow the directions that come with your software for the exact procedure for creating a bootable CD or DVD.

Troubleshooting Optical Drives

Failure Reading a CD/DVD

If your drive fails to read a CD or DVD, try the following solutions:

- Check for scratches on the disc data surface.
- Check the drive for dust and dirt; use a cleaning disc.
- Make sure the drive shows up as a working device in System Properties.
- Try a disc that you know works.
- Restart the computer (the magic cure-all).
- Remove the drive from Device Manager in Windows 9x or later versions, allow the system to redetect the drive, and then reinstall the drivers (if PnP-based system).

Failure to Read CD-R, CD-RW Discs in CD-ROM or DVD Drive

If your CD-ROM or DVD drive fails to read CD-R and CD-RW discs, try the following solutions:

- Check compatibility; some very old 1x CD-ROM drives can't read CD-R media. Replace the drive with a newer, faster, cheaper model.
- Many early-model DVD drives can't read CD-R, CD-RW media; check compatibility.
- The CD-ROM drive must be MultiRead compatible to read CD-RW because of the lower reflectivity of the media; replace the drive.
- If some CD-Rs but not others can be read, check the media color combination to see whether some color combinations work better than others; change the brand of media.
- Packet-written CD-Rs (from Adaptec DirectCD and backup programs) can't be read on MS-DOS/Windows 3.1 CD-ROM drives because of the limitations of the operating system.
- Record the media at a slower speed. The pits/lands created at faster speeds sometimes can't be read by older drives.
- If you are trying to read a packet-written CD-R created with Adaptec/Roxio DirectCD on a CD-ROM drive, reinsert the media into the original drive, eject the media, and select the option Close to Read on Any Drive.
- Download and install a UDF reader compatible with the packet-writing software used to create the CD-RW on the target computer. If you are not sure how the media was created, Software Architects offers a universal UDF reader/media repair program called FixUDF! (also included as part of WriteCD-RW! Pro). WriteDVD! Pro includes the similar FixDVD! UDF reader/media repair program for DVD drives.

Failure to Read a Rewritable DVD in DVD-ROM Drive or Player

If your DVD-ROM or DVD player fails to read a rewritable DVD, try the following solutions:

- *Reinsert DVD-RW media into the original drive and finalize the media.* Make sure you don't need to add any more data to the media if you use a first-generation (DVD-R 2x/DVD-RW 1x) drive because you must erase the entire disc to do so. You can unfinalize media written by second-generation DVD-R 4x/DVD-RW 2x drives. See your DVD-RW disc-writing software instructions or help file for details.
- *Reinsert DVD+RW media into the original drive and change the compatibility setting to emulate DVD-ROM.* See the section "DVD+RW Compatibility Mode," earlier in this chapter, for details.

- *Make sure the media contains more than 521MB of data.* Some drives can't read media that contains a small amount of data.

Failure to Create a Writable DVD

If you can't create a writable DVD but the drive can be used with CD-R, CD-RW, or rewritable DVD media, try the following solutions:

- *Make sure you are using the correct media.* +R and R media can't be interchanged unless the drive is a DVD±R/RW dual-mode drive.
- *Be sure you select the option to create a DVD project in your mastering software.* Some CD/DVD-mastering software defaults to the CD-R setting.
- *Select the correct drive as the target.* If you have both rewritable DVD and rewritable CD drives on the same system, be sure to specify the rewritable DVD drive.
- *Try a different disc.*
- *Contact the mastering software vendor for a software update.*

Failure Writing to CD-RW or DVD-RW 1x Media

If you can't write to CD-RW or DVD-RW 1x media, try the following solutions:

- *Make sure the media is formatted.* Use the format tool provided with the UDF software to prepare the media for use.
- *If the media was formatted, verify it was formatted with the same or compatible UDF program.* Different packet-writing programs support different versions of the UDF standard. I recommend you use the same UDF packet-writing software on the computers you use or use drives that support the Mount Rainier standard.
- *Make sure the system has identified the media as CD-RW or DVD-RW.* Eject and reinsert the media to force the drive to redetect it.
- *Contact the packet-writing software vendor for a software update.*
- *Disc might have been formatted with Windows XP's own limited CD writing software instead of a true UDF packet-writing program.* Erase the disc with Windows XP after transferring any needed files from the media; then format it with your preferred UDF program.
- *Contact the drive vendor for a firmware update.* See "[Updating the Firmware in a CD-RW or Rewritable DVD Drive](#)," later in this chapter.

ATAPI CD-ROM or DVD Drive Runs Slowly

If your ATAPI CD-ROM or DVD drive performs poorly, check the following items:

- Check the cache size in the Performance tab of the System Properties control panel. Select the quad-speed setting (largest cache size).
- Check to see whether the drive is set as the slave to your hard disk; move the drive to the secondary controller if possible.
- Your PIO (Programmed I/O) or UDMA mode might not be set correctly for your drive in the BIOS; check the drive specs and use autodetect in BIOS for the best results (refer to [Chapter 5](#), "BIOS").
- Check that you are using busmastering drivers on compatible systems; install the appropriate drivers for the motherboard's chipset and the operating system in use. See the section "Direct Memory Access and Ultra-DMA," earlier in this chapter.
- Check to see whether you are using the CD-ROM interface on your sound card instead of the ATA connection on the motherboard. Move the drive connection to the ATA interface on the motherboard.

and disable the sound card ATA if possible to free up IRQ and I/O port address ranges.

- Open the System Properties control panel and select the Performance tab to see whether the system is using MS-DOS Compatibility Mode for CD-ROM drive. If all ATA drives are running in this mode, see www.microsoft.com and query on "MS-DOS Compatibility Mode" for a troubleshooter. If only the CD-ROM drive is in this mode, see whether you're using CD-ROM drivers in **CONFIG.SYS** and **AUTOEXEC.BAT**. Remove the lines containing references to the CD-ROM drivers (don't actually delete the lines **REM** them), reboot the system, and verify that your CD-ROM drive still works and that it's running in 32-bit mode. Some older drives require at least the **CONFIG.SYS** driver to operate.

Poor Results or Slow Performance When Writing to CD-R Media

If you are having problems successfully writing data to a CD, see "[How to Reliably Record CDs](#)," earlier in this chapter. See the section "Updating the Firmware in a CD-RW or Rewritable DVD Drive."

Trouble Reading CD-RW Discs on CD-ROM

If you can't read CD-RW discs in your CD-ROM, try the following solutions:

- Check the vendor specifications to see whether your drive is MultiRead compliant. Some are not.
- If your drive is MultiRead compliant, try the CD-RW disc on a known-compliant CD-ROM drive (a drive with the MultiRead feature).
- Insert CD-RW media back into the original drive and check it for problems with the packet-writing software program's utilities.
- Insert CD-RW media back into the original drive and eject the media. Use the right-click Eject command in My Computer or Windows Explorer to properly close the media.
- Create a writable CD or DVD to transfer data to a computer that continues to have problems reading rewritable media.

Trouble Reading CD-R Discs on DVD Drive

If your DVD drive can't read a CD-R disc, check to see that the drive is MultiRead2 compliant because non-compliant DVDs can't read CD-R media. Newer DVD drives generally support reading CD-R media.

Trouble Making Bootable CDs

If you are having problems creating a bootable CD, try these possible solutions:

- Check the contents of the bootable floppy disk from which you copied the boot image. To access the entire contents of a CD, a bootable disk must contain CD-ROM drivers, **AUTOEXEC.BAT**, and **CONFIG.SYS**.
- Use the ISO 9660 format. Don't use the Joliet format because it is for long-filename CDs and can't boot.
- Check your system's BIOS for boot compliance and boot order; the CD-ROM should be listed first.
- SCSI CD-ROMs need a SCSI card with BIOS and bootable capability as well as special motherboard BIOS settings.

Updating the Firmware in a CD-RW or Rewritable DVD Drive

Just as updating the motherboard BIOS can solve compatibility problems with CPU and memory, support, USB ports, and system stability, upgrading the firmware in a rewritable CD or DVD drive can also solve

problems with media compatibility, writing speed, and digital audio extraction from scratched discs and even prevent potentially fatal mismatches between media and drives.

For example, I noticed that a Plextor CD-RW drive with a maximum CD-R writing speed of 40x was working near its maximum speed when writing to green-gold media brands such as Philips and Imation. However, when using azo blue/silver Verbatim media, performance sank to an average of 10x or less. A check of the Plextor website (www.plextor.com) revealed that the latest firmware upgrade improved results when Verbatim media was used. After I installed the update, the drive wrote at top speed to azo blue/silver, green-gold, and other types of CD-R media.

To determine exactly which problems a firmware update can solve for you, be sure to check your drive vendor's website.

Determining Whether You Might Need a Firmware Update

If you encounter any of the following issues, a firmware update might be necessary:

- Your drive can't use a particular type of media, or it performs much more slowly with one type of media than other types/brands of media.
- Your writing software stops recognizing the drive as a rewritable drive.
- You want to use faster media than what the drive was originally designed to use (particularly true with Pioneer drives).

Because any firmware update runs a risk of failure and a failed firmware update can render your drive useless (I've seen it happen), you shouldn't install firmware updates casually. However, as the preceding examples make clear, sooner or later you'll probably need one.

Note that firmware updates don't fix the following problems:

- Drive not recognized by a newly installed CD or DVD mastering program
- Drive not recognized by Windows XP's built-in CD writing program

Because each rewritable CD or DVD drive has special characteristics at present (in the future, Mount Rainier support will standardize drive characteristics), CD or DVD writing programs you buy at retail must have model-specific updates to work. Get the update from the software vendor, or use the software provided with the drive. If you are trying to use an OEM version of a program with a different drive model from the original, you will also need an update from the software vendor (in some cases, an OEM version works only with the original drive with which it was packaged).

Windows XP's built-in CD writing feature is a pale imitation of even the worst third-party CD mastering program, but if you insist on using it, be sure your drive is listed in the Windows Catalog of supported drives and devices (www.microsoft.com/windows/catalog). To install the latest updates for Windows XP, including updates to the CD writing feature, use Windows Update. Microsoft Knowledge Base article 320174 discusses an update to the CD writing feature. Search the Microsoft website for other solutions.

Determining Which Drive Model and Firmware Are Installed

Before you can determine whether you need a firmware update for your rewritable drive, you need to know your drive model and which firmware version it's using. This is especially important if you use a drive that is an OEM product produced by a vendor other than the one that packaged the drive for resale. You can use

the following methods to determine this information:

- Windows Device Manager (Windows 9x/Me)
- CD/DVD Mastering Software Drive Information

With the Windows 9x/Me Device Manager, follow this procedure:

1. Right-click My Computer and select Properties.
2. Click the Device Manager tab.
3. Click the plus (+) sign next to CDROM in the list of device types.
4. Double-click the rewritable drive icon to display its properties sheet.
5. Click the Settings tab; the firmware version and drive name will be displayed.

With Roxio Easy CD Creator 5, follow this procedure:

1. Click Tools.
2. Click CD-Drive Properties.
3. Click the drive letter.
4. The firmware revision and drive brand/model are listed along with other information.

With Nero Burning ROM 5.5, follow this procedure:

1. Click Recorder from the top-level menu.
2. Click the drive desired.
3. The drive model and firmware version are displayed along with other information.

After you have this information, you can go to your rewritable drive vendor's website and see whether a firmware update is available and what the benefits of installing the latest version would be.

Installing New Drive Firmware

Generally speaking, the firmware update procedure works like this, but you should be sure to follow the particular instructions given for your drive:

1. If the firmware update is stored as a Zip file, you need to use an unzipping program or the integrated unzipping utility found in some versions of Windows to uncompress the update to a folder.
2. If the drive maker provides a readme file, be sure to read it for help and troubleshooting. If the update file is an EXE file, it might display a readme file as part of step 3.
3. Double-click the EXE file to start the update process. Be sure to leave the system powered on during the process (which can take 23 minutes).
4. Follow the vendor's instructions for restarting your system.
5. After you restart your system, the computer might redetect the drive and assign it the next available drive letter. If you previously assigned the drive a customized drive letter (for example, on one computer in my organization, Q: is used for a CD-RW drive and R: for a DVD+RW drive), use the Device Manager in Windows 9x/Me or the Computer Management service in Windows 2000/XP to reassign the correct drive letter to the drive.

Troubleshooting Firmware Updates

If you have problems performing a rewritable drive firmware update, check the vendor's readme file or website for help. In addition, here are some tips we've found useful.

If the firmware update fails to complete, there might be interference from programs that control the drive, such as packet-writing programs (InCD, DirectCD) or the built-in Windows XP CD writing feature. To disable resident software, restart the computer in Safe Mode (Windows 2000/XP) and retry the update. Restart the system normally after the update is complete.

With Windows 9x/Me, you can use MSConfig (System Configuration Utility), select the Selective Startup option, and uncheck Load Startup Group Items and Process Win.INI File Before Restarting. After completing the firmware update, be sure to rerun MSConfig and select Normal Startup before restarting the computer.

To disable Windows XP's own CD writing feature for a particular drive, right-click the drive icon in My Computer, select Properties, click the Recording tab, and clear the check mark in the box next to Enable CD Recording on This Drive.

If the firmware update doesn't improve drive performance on a system running Windows 9x/Me, DMA might not be enabled on the rewritable drive. Refer to the section "Direct Memory Access and Ultra-DMA," earlier in this chapter, for details.

Chapter 12. Physical Drive Installation and Configuration

[Installing All Types of Drives](#)

[Hard Disk Installation Procedures](#)

[Formatting](#)

[Replacing an Existing Drive](#)

[Hard Disk Drive Troubleshooting and Repair](#)

[Installing an Optical Drive](#)

[Floppy Drive Installation Procedures](#)

Installing All Types of Drives

This chapter covers the actual installation of hard drives, optical drives (CD/DVD), floppy drives, and tape drives. This includes everything from preparing the components to setting jumpers to installing the actual cabling and physical installation. I also dig into some initial system software configuration issues, right up to the point of installing the operating system. From that point on, the steps you take depend on which operating system you are installing.

For more information on drive interfaces, magnetic storage, drive operation, and operating system issues, see the following chapters:

- [Chapter 7](#), "[The ATA/IDE Interface](#)"
- [Chapter 8](#), "[Magnetic Storage Principles](#)"
- [Chapter 9](#), "[Hard Disk Storage](#)"
- [Chapter 10](#), "[Removable Storage](#)"
- [Chapter 11](#), "[Optical Storage](#)"
- [Chapter 15](#), "[I/O Interfaces from Serial and Parallel to IEEE-1394 and USB](#)"

Although most of the drives you would install in a PC are covered here, the primary emphasis is on hard disks and other devices using Parallel ATA (also called IDE), Serial ATA (SATA), or SCSI interfaces. For USB or FireWire (IEEE 1394) devices, see [Chapter 15](#).

Hard Disk Installation Procedures

This section describes the hard disk drive installation process, particularly the configuration, physical installation, and formatting of a hard disk drive.

To install a hard drive in a PC, you must perform some or all of the following procedures:

- Configure the drive.
- Configure the host adapter (if used).
- Physically install the drive.
- Configure the system to recognize the drive.
- Partition the drive (FDISK, DISKPART, or SETUP).
- High-level format the partitions (FORMAT or SETUP).

As you perform the procedure, you might need to know various details about the hard disk drive, host adapter (if used), and system ROM BIOS, as well as many of the other devices in the system. This information usually appears in the various manuals or reference sheets that come with these devices. When you purchase these items, be sure the vendor includes any documentation that came with the original components. (Many do not include the manuals unless you ask for them.) For most equipment sold today, you will get enough documentation from the vendor to enable you to proceed.

If you are like me, however, and want all the technical documentation on the device, you should contact the original manufacturer of the device and order the technical specification manual. For example, if you purchase a system that comes with a particular ATA drive, the seller probably will give you some limited information on the drive, but not nearly the amount that the technical manual for the drive provides. To get this documentation, you normally download it from the drive manufacturer's website. The same rule applies for any of the other components in most of the systems sold today. I find the OEM technical manuals essential in providing the highest level of technical support possible. For reference, you can look up the hard disk manufacturer names in the Vendor List on the disc packaged with this book; you will find numbers to call for technical support, as well as URLs for their websites.

Drive Configuration

Before you physically install a hard disk drive in the computer, you must ensure that it is properly configured. For an ATA drive, this generally means designating the drive as a master/slave or using the Cable Select (CS) feature and a special cable to determine the relationship. For SCSI drives, you must set the device's SCSI ID and possibly its SCSI bus termination state.

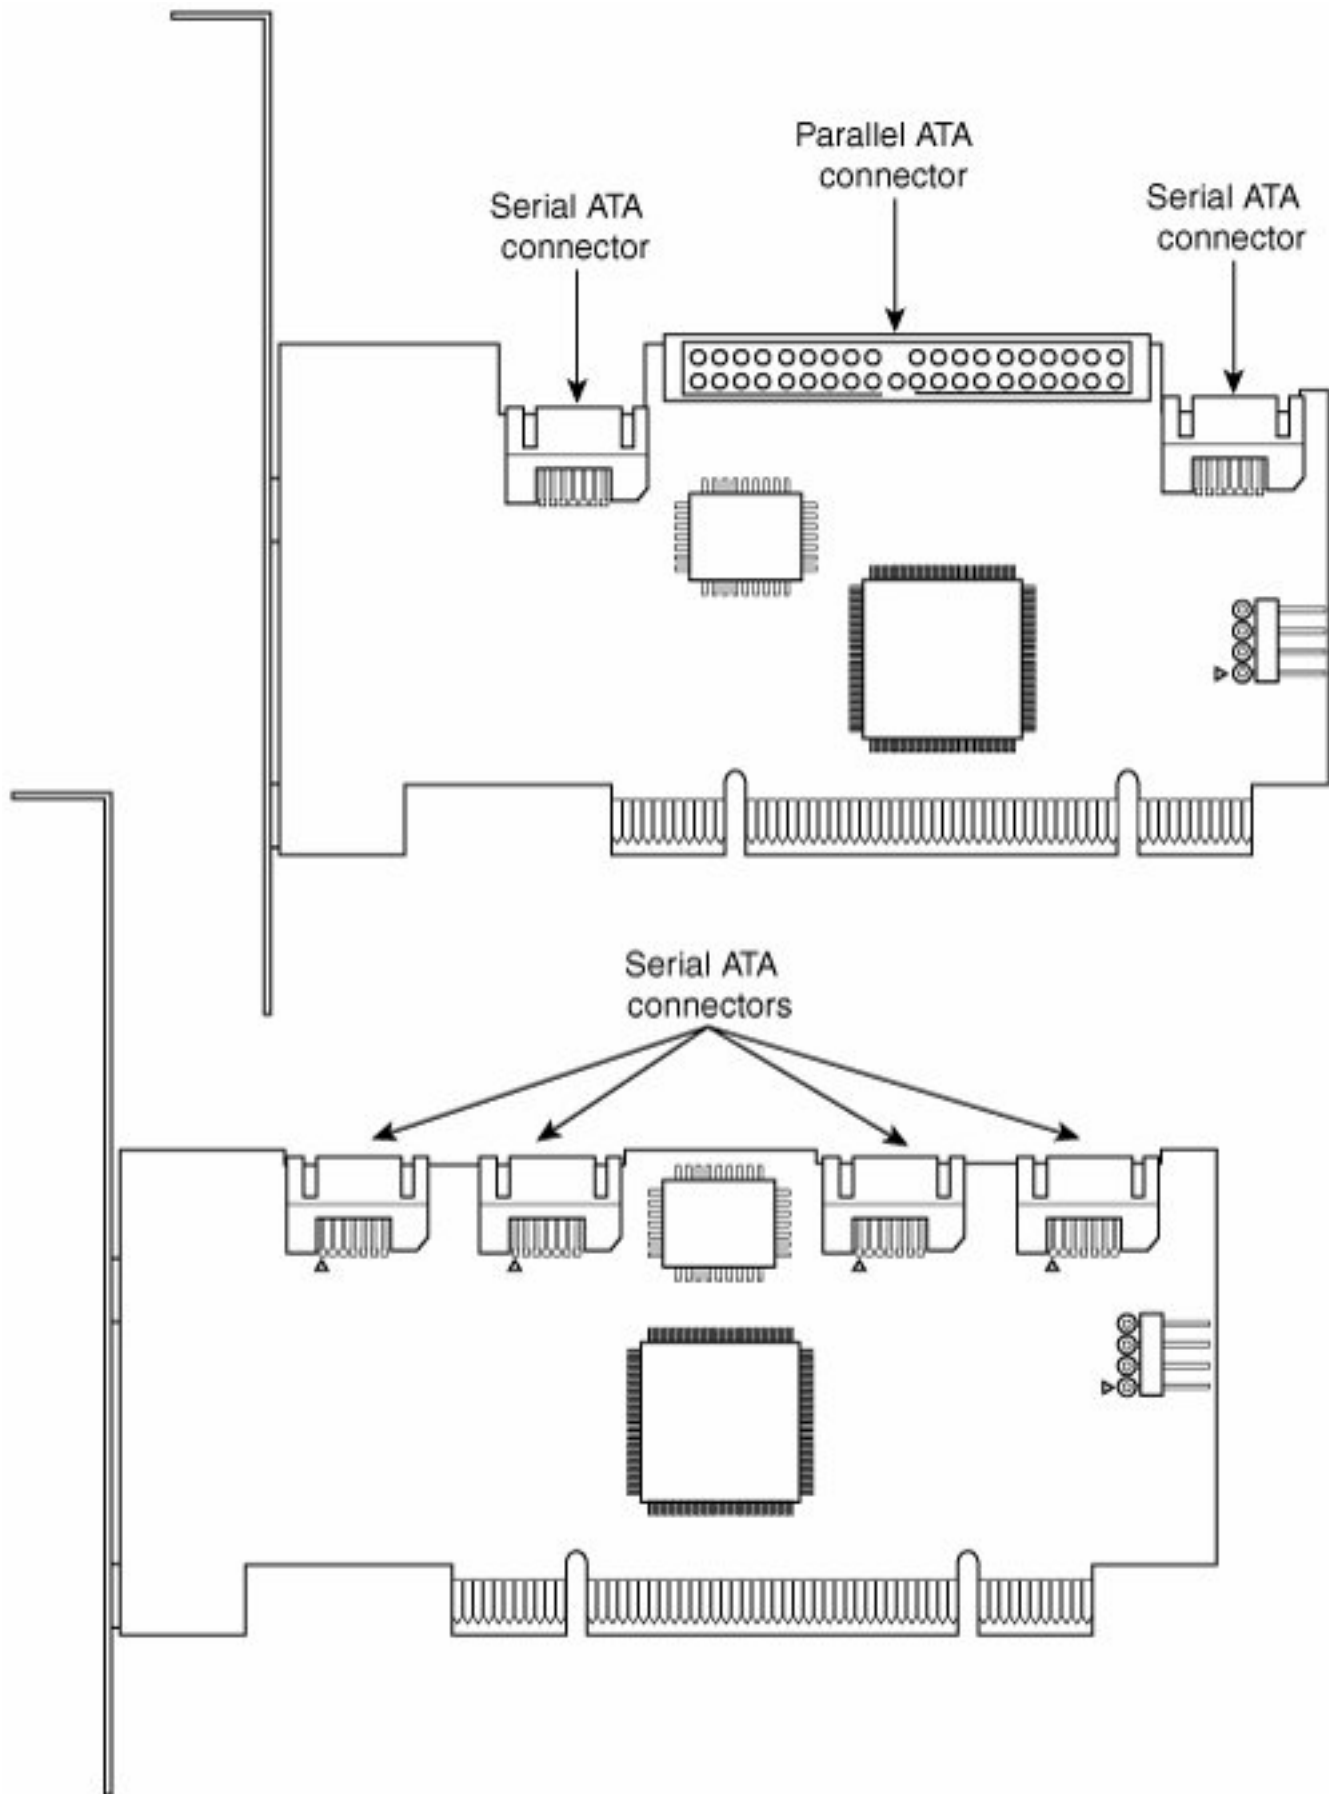

◀◀ To learn more about configuring ATA drives, see "[ATA Standards](#)," p. [552](#).

Serial ATA drives do not require configuration with jumper blocks. Although some SATA drives might have jumper blocks, they are intended for factory use only. Each SATA drive connects to the SATA host adapter in a point-to-point configuration using its own cable; there is no master or slave as there is with Parallel ATA drives. For compatibility, some SATA host adapters emulate master and slave configurations.

Host Adapter Configuration

Older hard disk drive types used separate disk controller cards you had to install in a bus slot. The ATA, SCSI, and SATA hard disk drives used in today's PCs, however, have the disk controller integrated into the drive assembly. For ATA drives, the I/O interface is nearly always integrated into the system's motherboard, and you configure the interface through the BIOS Setup. No separate host adapter exists; therefore, if you have an ATA drive, you can proceed to the section "Physical Installation" later in this chapter. Some systems might use ATA/IDE adapters in lieu of the built-in interface. This is because some of the motherboard-integrated ATA interfaces might not support the faster modes (such as Ultra-ATA/33 through Ultra-ATA/133) that most newer drives can use. In most cases, I would recommend upgrading the motherboard rather than getting an ATA host adapter because a new motherboard has other benefits and the cost isn't much higher. SATA drives can be connected to a system with a standard ATA interface by installing an SATA adapter card (see [Figure 12.1](#)). If the system has an SATA host adapter built in to the motherboard, no additional card is necessary.

Figure 12.1. You can install a combo SATA/ATA host adapter (top) or a pure SATA host adapter (bottom) to enable you to install SATA drives into a computer that has standard ATA host adapters.

SCSI drives, however, usually require a host adapter card you must install in a bus slot like any other card.

A few motherboards have integrated SCSI adapters, but these are rare. Configuring a SCSI host adapter card involves setting the various system resources the adapter requires. As with most expansion cards, a SCSI host adapter requires some combination of the following system resources:

- Boot ROM address (optional)
- Interrupt request (IRQ)
- Direct Memory Access (DMA) channel
- I/O port address

Not all adapters use every one of these resources, but some might use them all. In most cases with modern plug-and-play adapters and systems, the BIOS and your operating system automatically configure these resources. The computer sets the required hardware resource settings to values that do not conflict with other devices in the computer.

◀◀ See "[Plug and Play BIOS](#)," p. [464](#).

Note

A detailed list of PnP device IDs is included in the Technical Reference section of the disc included with this book.

If your hardware or operating system does not support Plug and Play, you must manually configure the adapter to use the appropriate resources. Some adapters provide software that enables you to reconfigure or change the hardware resources, whereas others might use jumpers or DIP switches on the adapter card.

◀◀ See "[System Resources](#)," p. [381](#).

The ATA interface driver is part of the standard PC BIOS, which enables booting from an ATA drive. Systems that include SATA interfaces on the motherboard also incorporate support for SATA into the BIOS. The BIOS provides the device driver functionality the system needs to access the drive before any files can be loaded from disk. However, a SCSI interface driver is not part of the standard PC BIOS, so most SCSI host adapters have their own onboard ROM BIOS that enables SCSI drives to function as bootable devices.

Note

Although standard ATA drivers are provided with Windows, this interface is typically built in to the motherboard chipset South Bridge or I/O Controller Hub (ICH) component, and it usually requires that specific chipset drivers be loaded. If you are using a motherboard that is newer than your operating system version (for example, a board purchased new after 2002 that is used with Windows XP), be sure you install the chipset drivers that came with your motherboard immediately after installing Windows. If the board is older than the OS, the chipset drivers will most likely be present on the OS installation CD; however, it is still a good idea to update to the latest chipset drivers immediately after the OS installation.

Use of the SCSI BIOS is usually optional. If you are not booting from a SCSI drive, you can leave the BIOS on the card disabled and merely install the appropriate device driver to access the SCSI devices. Most host adapters have switches, jumpers, or configuration software you can use to enable or disable SCSI BIOS support.

In addition to providing boot functionality, the SCSI BIOS can provide many other functions, including any or all of the following:

- Low-level formatting
- Drive-type (parameter) control
- Host adapter configuration
- SCSI diagnostics
- Support for nonstandard I/O port addresses and interrupts

If the adapter's onboard BIOS is enabled, it uses specific memory address space in the upper memory area (UMA). The UMA is the top 384KB in the first megabyte of system memory. It is divided into three areas of two 64KB segments each, with the first and last areas being used by the video adapter circuits and the motherboard BIOS, respectively. Segments C000h and D000h are reserved for use by adapter ROMs, such as those found on disk controllers or SCSI host adapters.

Note

You must ensure that any adapters using space in these segments of the UMA (upper memory area) do not overlap with another adapter that uses this space. No two adapters can share this memory space. Most adapters have software, jumpers, or switches that can adjust the configuration of the board and change the addresses it uses to prevent conflict.

Physical Installation

The procedure for the physical installation of a hard disk drive is much the same as that for installing any other type of drive. You must have the correct screws, brackets, and faceplates for the specific drive and system before you can install the drive.

Some computer cases require plastic or metal rails that are secured to the sides of a hard disk drive so it can slide into the proper place in the system (see [Figure 12.2](#)). Other case designs have drive bays that directly accept the drive via screws through the side supports and no other hardware is necessary, whereas others use a cage arrangement where you first install the drives into a cage and then slide the cage into the case (see [Figure 12.3](#)). If your case uses rails or a cage, these are usually included with the case. With the proper mounting mechanism supplied via the case, all you need is the bare drive to install.

Figure 12.2. A typical 3 1/2" hard disk with mounting rails for a 3 1/2" drive bay.

[\[View full size image\]](#)

Figure 12.3. A typical hard disk mounted in a removable drive cage.

Because parallel ATA, SCSI, and SATA drives use different cables, be sure you have the proper cable for both your drive and controller/host adapter. For example, to run ATA-66 or faster modes (through ATA-133), you need a special 80-conductor cable that supports the CS feature. This cable is also recommended even if you are running Ultra-ATA/33, and it works for all slower modes as well. To determine whether your cable has 40 or 80 conductors, simply count the ridges on the ribbon cable—each ridge contains a conductor (wire). Another indication is that the 80-conductor cable typically has the motherboard connector end color-coded blue, and the master and slave drive connectors color-coded black and gray, respectively.

If you need additional drive-mounting hardware not included with either your case or the drive, several companies that specialize in drive-mounting brackets, cables, and other hardware accessories are listed in

the Vendor List (on the accompanying disc). If you intend to install a 3 1/2" hard drive in a 5 1/4" drive bay, you need yet another type of mounting bracket (as shown in [Figure 12.4](#)). Many 3 1/2" hard drives come with these brackets, or one might be supplied with your case or chassis.

Figure 12.4. A typical bracket used to mount a 3 1/2" drive in a 5 1/4" drive bay. The bracket is screwed to the drive and then mounted in the bay by using screws or rails, as determined by the case.

Note

You should also note the length of the drive cable itself when you plan to add a hard disk drive. It can be very annoying to assemble everything you think you'll need to install a drive and then find that the drive cable is not long enough to reach the new drive location. You can either try to reposition the drive to a location closer to the interface connector on the host adapter or motherboard or just get a longer cable. ATA cables are limited to 18" in overall length according to the standard; shorter is fine, but longer ones can cause signal integrity problems. This is most important if your drive is going to use the faster ATA-33 through ATA-133 modes. Using a cable that is too long causes timing errors and signal degradation, possibly corrupting the data on your drive. I see many 24"36" cable assemblies being sold or used in systems; you are asking for trouble if you violate the 18" maximum-length specification.

Different faceplate, or bezel, options are also available. Make sure you have the correct bezel for your application. Some systems, for example, do not need a bezel; if a bezel exists on the drive, you must remove it.

Caution

Be sure you use only the screws that come with your new drive. Many drives come with special short-length screws that may have the same size thread as other screws you might use in your system, but that should not be interchanged. If you use screws that are too long, they might protrude too far into the drive casing and cause problems.

The step-by-step procedures for installing an ATA hard drive are as follows:

1. Check your computer for an unused ATA/IDE connector. Typical Pentium-class and newer PCs have two ATA/IDE connectors, allowing for up to four ATA/IDE devices.

You might need an additional cable if both master and slave connectors are used on the primary cable and you are adding a third device.

Tip

Usually it is best for performance to keep devices that will be simultaneously active, such as hard drives and optical drives, on separate cables.

2. Double-check the pin configuration and cable type. The colored (normally red or red-flecked) stripe on one edge of the cable goes to pin 1 of the hard drive's data connector. Most cables and drive connectors are keyed to prevent improper (backward) installation, but many are not. Keying can be done via missing and plugged pins, a ridge on one side of the connector, or both. One tip to note is that pin 1 on the drive connector is almost always oriented nearest to the power connector.

Tip

Newer ATA drives that operate in the faster Ultra-DMA modes (ATA-66 through ATA-133) require a special 80-conductor cable, whereas lesser drives can use a 40-conductor cable. Note that you can always use the superior 80-conductor cable for slower drives, so normally that is all I recommend purchasing. SCSI drives use either 50-pin or 68-pin (wide) cables.

3. Configure the drive jumpers. If the drive is ATA/IDE and you are using a cable that supports CS, you must set the CS jumper on any drives connected to that cable. Otherwise, you must set the drives on the cable as either master or slave. Note that some older drives also required a slave-present jumper be set if the drive was configured as a master with a slave drive on the same cable. You'll find more detail on the drive configuration procedures later in this chapter.

- Slide the drive carefully into a drive bay of the correct size. Most hard drives except for a few very high-capacity SCSI drives meant for servers and the now-discontinued Quantum Bigfoot series are 3 1/2" wide and 1" high. If you have no 3 1/2" drive bays left for your hard disk, attach a drive-adaptor kit to the sides of the drive to make it wide enough to fit into a 5 1/4" wide drive bay (refer to [Figure 12.4](#)). Some case designs require you to attach rails to the side of the hard drive. If so, attach them to the drive using the screws supplied with either the case or the drive. Be sure the screws aren't too long; if you bottom the screws in the drive, you can damage it. Then, slide the drive into the bay in the case until the rails latch into place.

Note

You can find more visual step-by-step instructions for installing a hard drive in [Chapter 20](#), "Building or Upgrading Systems."

- Attach the data cable connector to the back of the drive, unless you are adding the drive and cable at the same time. In that case, attach the cable to the drive before you slide it into the drive bay and fasten it into place (step 2).
- Attach the appropriate power connector to the drive. Most hard drives use the larger, or "Molex," four-wire power connector. If necessary, purchase a Y-splitter cable (see [Figure 12.5](#)) to create two power connectors from one (many computers have fewer power connectors than drive bays).

Figure 12.5. Power cord splitter and connector.

- Turn on the computer and listen for the new hard disk to spin up. Even though today's drives are very quiet compared to early hard disks, you should usually still be able to hear a faint hum as the new hard disk starts to run. Failing that, you can often sense a hard drive spin up by touch. If you don't hear anything from the drive, double-check the data and power cables.

8. Restart the computer and access the BIOS setup screens to configure the new hard disk. If your BIOS has an autodetect or auto type setting, I recommend you use it because it will configure the parameters automatically using optimal settings. For ATA hard drives above 528MB (504MiB), you also must set logical block address (LBA) translation to access the drive's full capacity. If autodetect was selected, LBA translation should already be set correctly. Many systems have a Peripherals Configuration screen, which also enables you to set transfer speeds for maximum drive performance, but again these should be configured automatically if you enabled autodetect. If your BIOS can't autodetect your drive, see the documentation that came with the drive for the correct settings. Most drives have the CHS parameters as well as jumper setting information displayed on a sticker attached to the drive, and all modern BIOSs support autodetect, as well. Save the BIOS configuration and exit the BIOS Setup screen to continue. See the section "System Configuration," later in this chapter, for more information on this step because it can be complicated.
9. With your operating system boot CD or floppy in the appropriate drive, restart the computer. If you intend to install the operating system, Windows 98 or later will automatically guide you through the partitioning and formatting process during the operating system installation. If you want, you can partition and format the drive before installing the OS, by using the operating system's disk partitioning software.

If you use Windows 9x or Me, FDISK can be found on the operating system start disk, such as the Windows startup disk. Simply insert the startup disk in the floppy drive, boot from it, and type the **FDISK** command at the **A:** prompt. Windows 2000 and XP use the **DISKPART** command or the Disk Management utility.

See "[ATA Standards](#)," p. [552](#).

Physical Installation Issues for SATA Drives

The step-by-step procedure for installing an SATA hard drive differs from the ATA drive installation as follows:

1. Check your computer for an unused SATA connector. Even though some new computers and motherboards have one or two SATA connectors, you might need to install a separate SATA host adapter card on many systems. If you need to install a separate SATA host adapter, consult its manual for physical and driver installation instructions.

2. Connect the SATA data cable to the SATA host adapter. SATA data cables can be combined with the SATA power cable or be separate. If the SATA data cable is separate from the SATA power cable, either end of the cable can be used for the drive or host adapter (see [Figure 12.6](#)).

Figure 12.6. SATA data and power cables can be separate (top) or be combined into a single molded assembly (bottom).

3. Slide the drive carefully into a drive bay of the correct size, as in step 4 of the ATA host adapter installation in the previous section.
4. Attach the SATA data cable connector to the back of the drive, unless you are adding the drive and cable at the same time. In that case, attach the cable to the drive before you slide it into the drive bay and fasten it into place.
5. Attach the appropriate power connector to the drive. Because most power supplies don't have an SATA power connector, you might need to purchase a Molex 12V-to-SATA power converter cable if one was not provided with your drive. This converter connects to a standard 4-pin Molex power connector into an SATA power connector.

From this point, the remainder of the installation is the same as with a standard ATA drive.

Physical Installation Issues for SCSI Drives

The step-by-step procedure for installing a SCSI hard drive differs from the ATA drive installation as follows:

1. Check your computer for a SCSI host adapter card unless your computer has a SCSI host adapter on the motherboard. If the SCSI host adapter already has a ribbon cable connected to it, verify that an empty connector is available. If the SCSI host adapter doesn't have a ribbon cable connected to it, you must attach a ribbon cable with the correct pinout to the host adapter.
2. Verify that the SCSI drive has been configured to use a unique SCSI device ID number. Generally, this is done by adjusting jumpers on the rear of the drive.
3. Configure the terminator jumpers correctly, according to whether the drive is the only internal drive (termination on) or is being added to a cable after an existing drive (termination on for the new drive and termination off for the existing drive).
4. Slide the drive carefully into a drive bay of the correct size, as in step 4 of the ATA host adapter installation.
5. Attach the SCSI data cable connector to the back of the drive, unless you are adding the drive and cable at the same time. In that case, attach the cable to the drive before you slide it into the drive bay and fasten it into place.
6. Attach the appropriate power connector to the drive, as in step 6 of the ATA host adapter installation.

7. Turn on the computer and listen to the drive, as in step 7 of the ATA host adapter installation.
8. After the computer starts, start the SCSI host adapter drive configuration utility and configure your host adapter and drive. See the SCSI host adapter manual for details.
9. Run your operating system's disk preparation program, as described in step 9 of the ATA host adapter installation.

System Configuration

After your drive is physically installed, you must provide the computer with basic information about the drive so the system can access and boot from it. How you set and store this information depends on the type of drive and system you have. Standard ATA setup procedures apply for most hard disks (including SATA drives) except SCSI drives. SCSI drives usually follow a custom setup procedure that varies depending on the host adapter you are using. If you have a SCSI drive, follow the instructions included with the host adapter to configure the drive.

Automatic Drive Detection

For ATA drives, virtually all new BIOS versions in today's PCs have automatic parameter detection (autodetect). The BIOS sends a special Identify Drive command to all the devices connected to the ATA interface during the system startup sequence; the drives are intelligent enough to respond with the correct parameters. The BIOS then automatically enters the parameter information returned by the drive. This procedure eliminates errors or confusion in parameter selection.

Manual Drive Parameters

If you are dealing with a motherboard that does not support autodetect, you must enter the appropriate drive information in the system BIOS manually. The BIOS has a selection of preconfigured drive types, but these are woefully outdated in most cases, providing support only for drives holding a few hundred megabytes or less. In nearly every case, you must select the user-defined drive type and provide values for the following settings:

- Cylinders
- Heads
- Sectors per track

The values you use for these settings should be provided in the documentation for the hard disk drive, but they also might be printed on the drive itself. It's a good idea to check for these settings and write them down because they might not be visible after you've installed the drive. You also should maintain a copy of these settings in case your system BIOS loses its data due to a battery failure. One of the best places to store this information is inside the computer itself. Taping a note with vital settings such as these to the inside of the case can be a lifesaver.

In the event that you are unable to determine the correct settings for your hard drive from either the drive case or the Technical Reference, utility programs are available on the Internet that can query the drive for this information.

Depending on the maker and version of your system BIOS, you might have to configure other settings as

well, such as which transfer mode to use and whether the BIOS should use logical block addressing.

See "[ATA Drive Capacity Limitations](#)," p. [579](#).

Formatting

Proper setup and formatting are critical to a drive's performance and reliability. This section describes the procedures used to format a hard disk drive correctly. Use these procedures when you install a new drive in a system or immediately after you recover data from a hard disk that has been exhibiting problems.

The three major steps in the formatting process for a hard disk drive subsystem are as follows:

1. Low-level formatting
2. Partitioning
3. High-level formatting

Low-Level Formatting

All new hard disk drives are low-level formatted by the manufacturer, and you do not have to perform another LLF before you install the drive. In fact, under normal circumstances, you should not ever have to perform a low-level format on an ATA or SCSI drive. Most manufacturers no longer recommend that you low-level format any ATA type drive.

This recommendation has been the source of some myths about ATA. Many people say, for example, that you can't perform a low-level format on an ATA drive, and that if you do, you will destroy the drive. This statement is untrue! What can happen with some of the earliest ATA drives is that you might lose the optimal head and cylinder skew factors that were set by the manufacturer for the drive, as well as the map of drive defects. This can have a negative effect on the drive's performance, but you can still reliably use the drive. Note that all drives that internally use a zoned recording (where there is a variable number of sectors per track internally) are immune to any problems due to low-level formatting because the actual sector marks can't be rewritten. This includes pretty much all modern ATA drives made in the last 12 years.

However, sometimes you must perform a low-level format on an ATA or a SCSI drive. The following sections discuss the software you can use to do this.

SCSI Low-Level Format Software

SCSI drives also come preformatted, and unless there is a problem with the drive, you will not have to perform this operation yourself. If you do want to low-level format a SCSI drive, you must use the LLF program provided by the manufacturer of the SCSI host adapter. The designs of these devices vary enough that a register-level program can work only if it is tailored to the individual controller. Fortunately, all SCSI host adapters include low-level format software, either in the host adapter's BIOS or in a separate disk-based program.

The interface to the SCSI drive is through the host adapter. SCSI is a standard, but no true standards exist for what a host adapter is supposed to look like. This means that any formatting or configuration software

is specific to a particular host adapter.

Note

Notice that SCSI format and configuration software is keyed to the host adapter and is not specific in any way to the particular SCSI hard disk drive you are using. Because of differences in how various SCSI host adapters view the contents of a SCSI hard disk, if you move a SCSI hard disk containing data to a different SCSI host adapter, the data on the hard disk might not be recognized.

ATA Low-Level Format Software

ATA drive manufacturers have defined and standardized extensions to the original WD1002/1003 hard disk controller card to AT-bus (ISA) interface, which is known as the ATA (AT Attachment) interface. The ATA specification provides for vendor-unique commands, which are manufacturer proprietary extensions to the standard. To prevent improper low-level formatting, many of these ATA drives have special codes that must be sent to the drive to unlock the format routines. These codes vary among manufacturers. If possible, you should obtain LLF and defect management software from the drive manufacturer; this software usually is specific to that manufacturer's products and often is model specific. Check the brand and model number of your hard disk to determine the utility program you need.

Most ATA drives are protected from any alteration to the skew factors or defect map erasure because they are always in a translated mode internally. Zoned bit recording drives are always under translation and are fully protected. Most ATA drives have a custom command set that must be used in the format process; the standard format commands defined by the ATA specification usually do not work, especially with intelligent or zoned bit recording ATA drives. Without the proper manufacturer-specific format commands, you can't perform the defect management by the manufacturer-specified method, in which bad sectors often can be spared.

Most manufacturers supply low-level format programs for their drives. Here are a few examples:

- *Seagate/Conner Peripherals.* [ftp.seagate.com/techsuppt/seagate_utils/sgatfmt4.zip](ftp://ftp.seagate.com/techsuppt/seagate_utils/sgatfmt4.zip) or www.seagate.com/support/seatools
- *Hitachi/IBM.* <http://www.hitachigst.com/hdd/support/download.htm>
- *Maxtor/Quantum.* www.maxtor.com/en/support/downloads/index.htm
- *Samsung.* www.samsung.com/Products/HardDiskDrive/utilities/hutil.htm or www.samsung.com/Products/HardDiskDrive/utilities/sutil.htm or www.samsung.com/Products/HardDiskDrive/utilities/shdiag.htm
- *Western Digital.* <http://support.wdc.com/download/>

You should try the manufacturer-specific format programs first. They are free, can often work at a lower level, and can handle defects in ways that the more generic ones can't. If formatting software is not available from your drive's manufacturer, I recommend Disk Manager by Ontrack and the Micro-Scope program by Micro 2000. Another excellent, inexpensive, general-purpose PC hardware diagnostic that includes low-level format capability is the Hitachi (formerly IBM) Drive Fitness Test (DFT) program. The Drive Fitness Test program works on non-Hitachi and non-IBM drives as well and performs a detailed and thorough test of your hard drive. I recommend this as one of the best general-purpose drive test programs on the market because it can do a fairly thorough test in nondestructive mode. It performs an LLF

(destructive) only on IBM- and Hitachi-brand drives. You can download DFT from the Hitachi site listed previously.

Note

Although Ontrack Disk Manager can be purchased in a "generic" version that works with any manufacturer's hard drives, brand-specific OEM versions are often available free of charge on the utility disks or CD-ROMs shipped with new retail-packaged hard disk drives. You should also check your drive maker's website for updated versions of Disk Manager. These OEM versions are designed to check for a particular brand's drive firmware and do not work on any brand other than the one for which they are modified.

Nondestructive Formatters

General-purpose, BIOS-level, nondestructive formatters, such as Calibrate (older Symantec Norton Utilities) and SpinRite (Gibson Research), are not recommended in most situations in which a real LLF is required. These programs have several limitations and problems that decrease their effectiveness; in some cases, they can even cause problems with the way defects are handled on a drive. These programs attempt to perform a track-by-track LLF by using BIOS functions, while backing up and restoring the track data as they go. These programs do not actually perform a complete LLF because they do not even try to low-level format the first track (Cylinder 0, Head 0) due to problems with some controller types that store hidden information on the first track.

These programs also do not perform defect mapping in the way standard LLF programs do, and they even can remove the carefully applied sector header defect marks during a proper LLF. This situation potentially enables data to be stored in sectors that originally were marked defective and might actually void the manufacturer's warranty on some drives. Another problem is that these programs work only on drives that have already been formatted and can format only drives that are formattable through BIOS functions.

Note

SpinRite is useful for recovering data found on drives with read errors because of its thorough method of repeatedly rereading the errors and analyzing the results to reconstruct the missing data.

A true LLF program bypasses the system BIOS and sends commands directly to the disk controller hardware. For this reason, many LLF programs are specific to the disk controller hardware for which they are designed. Having a single format program that will run on all types of controllers is virtually impossible. Many hard drives have been incorrectly diagnosed as being defective because the wrong format program was used and the program did not operate properly.

Drive Partitioning

Partitioning a hard disk is the act of defining areas of the disk for an operating system to use as a volume.

When you partition a disk, the partitioning software writes a master partition boot sector at Cylinder 0, Head 0, Sector 1—the first sector on the hard disk. This sector contains data that describes the partitions by their starting and ending cylinder, head, and sector locations. The partition table also indicates to the ROM BIOS which of the partitions is bootable and, therefore, where to look for an operating system to load.

The FDISK program is the accepted standard for partitioning hard disk drives for use with all operating systems up through Windows Me. Windows 2000 and XP use a similar command-line program called DISKPART, or you can partition and format hard disks with the Disk Management tool. All versions of Windows starting with Windows 95 can also partition and format the drive using the SETUP program for installing the OS. These programs are included with your operating system, and although they might have the same name and basic functions with any OS, you should typically use the tools that specifically came with your OS. Partitioning prepares the boot sector of the disk in such a way that the FORMAT program or the Windows SETUP format utility can operate correctly. Partitioning also enables various operating systems to coexist on a single hard disk. No matter which operating system you use, it should come with an FDISK, DISKPART, or SETUP program that can be used to partition the drive.

Note

Because FDISK, DISKPART, and SETUP depend on BIOS information about the hard disk to determine the size and drive geometry of the hard disk, having correct BIOS settings saved in the BIOS Setup is vital to the correct operation of these programs. If a 100GB hard drive is defined in the BIOS as a 100MB hard drive, for example, all these programs will see is 100MB.

With any version of Windows as with MS-DOS, FDISK or other disk preparation tools enable you to create two types of disk partitions: primary and extended. A primary partition can be bootable but an extended partition can't. If you have only a single hard disk in your system, at least part of the drive must be prepared as a primary partition if you want to start your computer from the hard disk (and who doesn't?). A primary partition is seen as a single volume or drive letter (C: on one-drive systems), whereas an extended partition acts as a sort of logical container for additional volumes (drive letters D: and beyond). A single extended partition can contain a single volume (also referred to by FDISK as a *logical DOS drive*) or several volumes (logical DOS drives) of various sizes.

Don't get hung up on the fact that FDISK calls partitions "DOS" partitions or "DOS" drives. This is true even though the operating system you are installing is Windows 95, 98, Me, NT, 2000, XP, Linux, and so on.

Depending on the version of Windows in use (and with any version of MS-DOS), you might need to subdivide a hard drive through the use of FDISK. The original release of Windows 95 and all MS-DOS versions support a file system known as FAT16, which allows no more than 65,536 files per drive and a single drive letter or volume size of no more than 2.1GB. Thus, a 10GB hard disk prepared with MS-DOS or the original Windows 95 (or 95A) must have a minimum of five drive letters and could have more (see [Figure 12.7](#)).

Figure 12.7. Adding a hard drive above 2.1GB in size to an MS-DOS or original Windows 95A computer forces the user to create multiple drive letters to use the entire drive capacity. The logical DOS drives are referenced like any other drive, although they are portions of a single physical hard disk.

Another reason for subdividing a single drive into multiple volumes is increased data security. For example, PowerQuest (the creator of PartitionMagic) suggests a three-volume partitioning scheme that looks like this:

C: for the operating system and utilities

D: for applications

E: and above for data

In this example, primary and extended partitions would be assigned as shown here:

C: the primary partition

D: and E: in the extended partition as logical DOS drives (volumes)

If a catastrophic failure to the disk structure wipes out C: or D:, drive E: which contains the data is usually still intact. This method also makes backing up the data easier; just set the backup program to back up all of E:, or all the changed files on E:.

Note

Although external USB and IEEE 1394a drives are normally preformatted and partitioned to allow immediate use, you can normally use FDISK/FORMAT or Disk Management to change the

partitions and file system used on the drive. See the external drive's instruction manual or the drive vendor's website for details.

Large Hard Disk Support

If you use the Windows 95B or above (Win95 OSR 2.x), Windows 98, Windows Me, or Windows 2000 versions of FDISK with a hard drive greater than 512MB, FDISK offers to enable large disk support.

Choosing to enable large disk support provides several benefits:

- *You can use a large hard disk (greater than 2.1GB) as a single drive letter.* In fact, your drive can be as large as 2TB and still be identified by a single drive letter. This is because of the FAT32 file system, which allows for many more files per drive than FAT16.
- *Because of the more efficient storage methods of FAT-32, your files will use less hard disk space overall.*

However, keep in mind that all disk operations must be performed through an operating system with FAT32 support (Windows 95B or later, Windows 98, Windows Me, or Windows 2000). If you have old MS-DOS games or applications that are bootable, you won't be able to access a FAT32 volume unless you replace the DOS version on the disk with the DOS included on Win95B or Windows 98. This normally can be done by using the **SYS A:** command from the **\Windows\Command** folder. Another option is to use the Windows Startup menu in Win95B or Win98 (press F8 as Windows starts to load) and select Command Prompt to get to a FAT32-capable DOS. On the other hand, you can select Start, Shutdown, Restart the Computer in MS-DOS Mode from the Windows desktop.

A drive prepared with the large hard disk support (FAT32) option enabled can still be partitioned into primary and secondary partitions with FDISK, as with FAT16 for the data-security reasons listed earlier.

Another type of file system is NTFS, which is supported by only Windows NT, Windows 2000, and Windows XP. This is a high-performance file system with additional security and networking features. NTFS was revised to NTFS5 in Windows NT 4.0 with Service Pack 4 and later, as well as Windows 2000 and Windows XP. Note that Windows 9x can't read NTFS partitions, and Windows NT can't read FAT32 partitions. Windows 2000 and Windows XP, however, can handle both FAT32 and NTFS.

Assigning Drive Letters with FDISK

FDISK can be used in many ways, depending on the number of hard drives you have in your system and the number of drive letters you want to create.

With a single drive, creating a primary partition (C:) and an extended partition with two logical DOS drives within it results in the following drive letters:

Partition Type Drive Letter(s)

Primary	C:
---------	----

Extended D: and E:

Most people think that a second physical drive added to this system should have drive letters that follow the E: drive.

However, you must understand how drive letters are allocated by the system to know how to use FDISK correctly in this situation. [Table 12.1](#) shows how FDISK assigns drive letters by drive and partition type.

Table 12.1. Drive Letter Allocations by Drive and Partition Type

Drive	Partition	Order	Drive Letter
1st	Primary	1st	C:
1st	Extended	3rd	E:
2nd	Primary	2nd	D:
2nd	Extended	4th	F:

How does this affect you when you add another hard drive? If you prepare the second hard drive with a primary partition and your first hard drive has an extended partition on it, the second hard drive takes the primary partition's D: drive letter. This moves all the drive letters in the first hard drive's extended partition up one drive letter.

In the first example, a drive is listed with C: (primary partition), D:, and E: (extended partition volumes) as the drive letters (D: and E: were in the extended partition). [Table 12.2](#) indicates what happens if a second drive is added with a primary partition and an extended partition with two volumes (same setup as the first drive).

Table 12.2. Drive Letter Changes Caused by Addition of Second Drive with Primary Partition

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters After Adding Second Drive
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	E:, F:

2nd	Primary	2nd	D:
2nd	Extended	4th	G:, H:

After adding the second drive, the original drive letters D: and E: have now become E: and F:. The primary partition on the new drive has become D:, and the extended partition volumes on the second drive are G: and H:. Confused? Well, you better not be or you'll find yourself deleting or copying data to or from the wrong drive.

This principle extends to third and fourth physical drives as well: The primary partitions on each drive get their drive letters first, followed by logical DOS drives in the extended partitions.

One way to effect this is to partition additional drives with only extended partitionsin other words, do not create primary partitions on them. That enables the new drive's partitions to be seen only as additional letters, and the letters used by the first drive's partitions to remain unchanged.

If you're *adding* a drive to your system, you should now understand why preparing that second, third, or fourth drive with a primary partition is a bad idea. If you're installing an additional hard drive (not a replacement), remember that it can't be a bootable drive. And if it can't be bootable, there's no reason to make it a primary partition. FDISK allows you to create an extended partition using 100% of the space on any drive. [Table 12.3](#) shows the same example used in [Table 12.2](#) with the second drive installed as an extended partition.

Table 12.3. Drive Letter Allocations After Addition of Second Drive with Extended Partition Only

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters (After Adding Second Drive)
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	D:, E:
2nd	Primary	2nd		
2nd	Extended	4th		F:

When a new drive is added with only extended partition volumes, you can see that the original drive letters remain undisturbed. This arrangement is much easier to understand, and it prevents accidents with data because of drive letters changing. This operating system behavior also explains why some of the first computers with ATA-based (ATAPI) Iomega Zip drives had the Zip drive as D:, with a single hard disk identified as C: and E:. The Zip drive was treated as the second hard drive with a primary partition. Subsequently, Iomega changed the Zip drive format and driver so that the Zip disk is recognized as an extended partition at the end of the drive letter chain.

Running FDISK

When you run newer versions of FDISK, the first thing that happens is you are prompted with the following:

```
Do you wish to enable large disk support (Y/N).....? [Y]
```

If you answer Yes to this question, FDISK creates FAT32 volumes for all volumes created that are larger than 512MB. Answering No to this question forces FDISK to create only FAT16 volumes, which are limited to a 2GB maximum size and waste more space on the disk due to larger cluster sizes.

Normally, in a modern system you would answer Yes, allowing the use of FAT32. After answering the question, FDISK shows a menu similar to the following:

```
Current fixed disk drive: 1
```

```
Choose one of the following:
```

1. Create DOS partition or Logical DOS Drive
2. Set active partition
3. Delete partition or Logical DOS Drive
4. Display partition information
5. Change current fixed disk drive

```
Enter choice: [1]
```

Option 5 is shown only if FDISK detects more than one drive on your system (if more than one is entered via your BIOS Setup). In that case, FDISK defaults to the first drive, and via option 5 you can cause FDISK to work with any of the other hard disks on the system.

To create partitions, you select option 1. If the drive is already partitioned, however, you can use option 4 to display the current layout of the drive.

After selecting option 1, the menu changes to enable you to create primary or extended partitions on a drive as follows:

```
Create DOS Partition or Logical DOS Drive
```

```
Current fixed disk drive: 1
```

```
Choose one of the following:
```

1. Create Primary DOS Partition
2. Create Extended DOS Partition
3. Create Logical DOS Drive(s) in the Extended DOS Partition

```
Enter choice: [1]
```

The rules require you to create a primary partition first on the boot drive, but on a secondary or nonboot drive, you can create just an extended partition if you choose. So, if you are partitioning the first drive in a

system and it will be bootable, you would choose option 1.

At this point, you are prompted to decide whether you want to use the maximum available size for a Primary DOS Partition. If you say Yes and you're using FAT32, the primary partition uses the entire drive. Conversely, if you say Yes and you did not enable large drive support (meaning you are using FAT16), the partition uses the entire drive or 2GB, whichever is smaller.

If you decide to create a primary partition that is not the full drive, you should go back through the menus and create an extended partition using the rest of the drive, and then further divide it into logical drives. Normally, I recommend making the primary partition the full size of the drive, keeping all of the drive as one letter. But there are various reasons you might want to split the drive into multiple partitions, such as for different operating systems, different file systems, applications, and so on.

After all the partitions are created, the final operation is to make one of them active (bootable), which is option 2 from the main FDISK menu. Typically, the only one that can be active is the primary partition. After that is done, all FDISK operations are complete, and you can exit the program.

When exiting FDISK after making partition changes, the system must be rebooted before these changes will be recognized. After rebooting, you must then high-level format each of the volumes with the operating system **FORMAT** command, which then allows the operating system to store files on them.

The C: volume usually must be formatted with the system files, although when you install Windows via the Windows Setup command, it detects whether the system files are present and offers to install them for you.

Drive Partitioning and Formatting with Disk Management

Even though Windows 2000 and Windows XP have a very powerful command-line tool called DISKPART that provides FDISK-like capabilities, along with additional options useful for working with advanced disk structures such as RAID arrays and dynamic disks, most Windows 2000 and Windows XP users utilize the GUI-based Disk Management component of the Microsoft Management Console to perform hard disk partitioning and formatting when installing a new hard disk on an existing system.

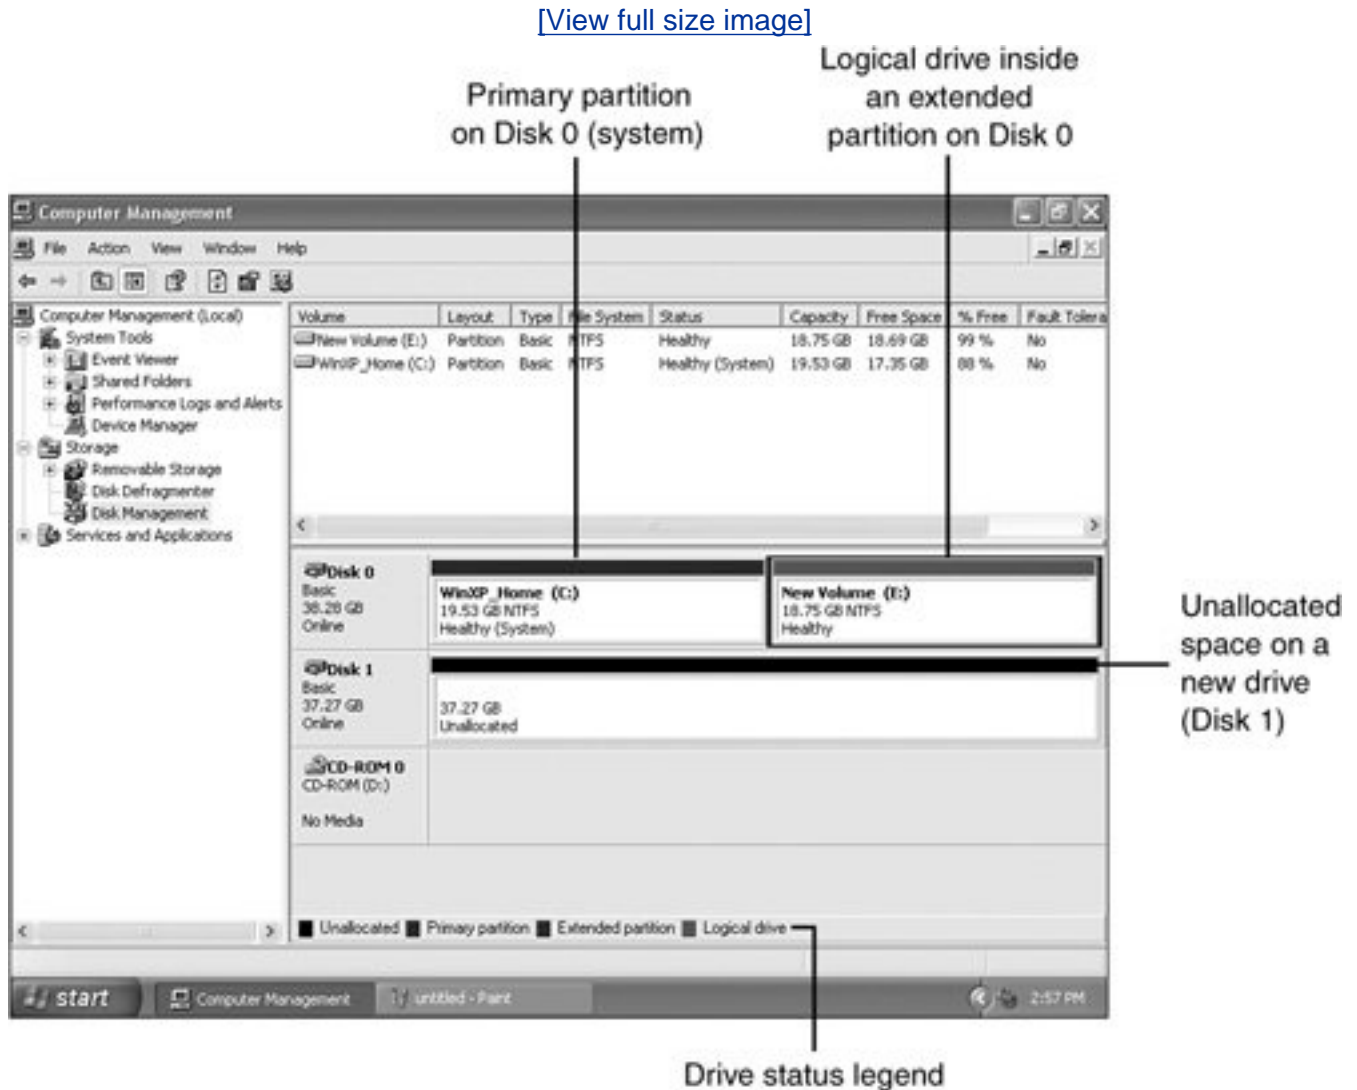

As with FDISK, you can select the type of file system you want to use, but the following differences exist between FDISK and Disk Management:

- *Disk Management is a true GUI-based utility.* Color-coded indicators for partition type and drive condition let you easily see which tasks you've performed with a drive. Wizards enable you to partition and format a drive under the guidance of Windows.
- *Disk Management supports more file systems than FDISK.* Whereas FDISK is limited to FAT-16 (and FAT-32 on Windows 95B and above, Windows 98, and Windows Me), Disk Management also supports NTFS.
- *Disk Management partitions and formats hard disks with a simple process.* Unlike FDISK, which requires you to restart the system before a new hard disk can be formatted and uses a separate FORMAT program to finish the job, Disk Management can perform both tasks without the need to restart the computer.
- *Disk Management uses drive letters not already in use for hard disk or optical drives, regardless of the partition type.* Unlike FDISK, which can scramble existing drive letter assignments if you prepare a new hard disk with a primary partition, Disk Management assigns a drive letter(s) to the new hard drive that follows those already in use. And, if installing a new drive causes conflicts with removable-media drives such as USB keychain or flash memory card readers you use occasionally, you can use Disk Management to select a different drive letter for the new hard disk or for existing hard disks or optical drives.

To use Disk Management to partition a new hard disk in Windows XP, do the following:

1. Open the Start menu, right-click My Computer, and select Manage from the context menu.
2. From the Computer Management screen, click Disk Management in the left window. The current hard disk drive letter is displayed in the upper-right window, and physical hard disks are displayed in the bottom-right window (see [Figure 12.8](#)). A newly installed drive is shown as unallocated space.

Figure 12.8. The Computer Management view of a system with a newly installed hard disk (Disk 1). Because New Volume (E:) was prepared after the CD-ROM drive (D:) was installed, it has a higher drive letter.

3. Select the new hard disk, right-click it, and select New Partition from the right-click menu to start the partitioning process.
4. Click Next at the opening screen of the New Partition Wizard.

5. Select Primary or Extended partition. Generally, you should choose an extended partition unless you want to create a primary partition that you can use to start the computer. Click Next to continue.
6. If you want to leave part of the hard disk unallocated, change the partition size. Otherwise, click Next to continue.
7. The New Partition Wizard displays the changes it's about to make to the new drive (see [Figure 12.9](#)). Click Finish to complete the partitioning process.

Figure 12.9. The New Partition Wizard prepares to create an extended partition from Disk 1.

8. After the wizard finishes, the Computer Management view displays the newly partitioned hard disk as free space. Right-click the partition, and select New Logical Drive to continue.
9. Click Next to continue with the wizard. Click Next again to select a logical drive.
10. To create more than one logical drive, change the maximum size of the partition size. To create a single logical drive, click Next.

11. Select the drive letter to assign. By default, the next available drive letter is displayed, but you can choose any unused drive letter. If you prefer, you can mount the new logical drive into an empty NTFS folder, or even not assign a drive letter or path. Click Next to continue.
12. Select the format options. By default, the new logical drive is formatted with NTFS, but you can choose FAT32 if the logical drive is 34.36GB (32GiB) or less. If the logical drive is larger than 32GiB, XP can only format the drive using NTFS. You can also specify the volume label, select a particular allocation unit (cluster) size, enable file/folder compression, and perform a quick format. If you want to format the drive later, select Do Not Format This Partition. Click Next to continue.
13. Again, the New Partition Wizard displays a list of changes to be made. Click Back to return to a particular menu if you need to make any changes, or click Finish to format the logical drive with the options selected (see [Figure 12.10](#)).

Figure 12.10. The New Partition Wizard prepares to format a logical drive on Disk 1 with the options shown.

14. Repeat steps 1014 if you didn't use all the free space as a logical drive and want to prepare additional logical drives.

No rebooting is necessary, and the color-coded legend at the bottom of the Disk Management display helps you track the status of the disk preparation process.

Drive Partitioning with Aftermarket Utilities

Alternative partitioning programs such as PartitionMagic by Symantec and Partition Commander by V-Communications enable you to take an existing hard drive and perform the following changes to it without loss of data:

- Create, resize, split, move, and merge partitions on the fly without losing data.
- Convert between file systems without losing data conversions include FAT to FAT32 and NTFS; FAT32 to FAT; NTFS to FAT and FAT32; primary to logical and vice versa; and FAT32 to NTFS under Windows 2000 and XP. It also includes support for ext2 and Linux SWAP file systems.
- Move applications between partitions and automatically update the drive-letter references after partitioning with PartitionMagic's DriveMapper utility.
- Undelete FAT, FAT32, Linux ext2, and NTFS partitions that have been deleted. You can restore partitions that have been deleted on disk as long as the space has not been reallocated or written over.
- Copy or move a partition to another partition or drive.

Note

I still recommend FDISK, DISKPART, Disk Management, or SETUP be used for initial partitioning and setup of any drive (these utilities destroy existing data), but these aftermarket utilities can be very useful for reconfiguring a system that is already partitioned.

Although the program recommends a full backup before starting, I've used these utilities many times to turn a single "big drive" into two or more drive letters in less than 10 minutes. Performing the same task with backup software and FDISK/FORMAT can take several hours because you must back up your existing drive, remove existing partitions with FDISK, create new partitions with FDISK, restart your computer, format the new drives, and reload your operating system and your backup.

High-Level (Operating System) Formatting

The final step in the installation of a hard disk drive is the high-level format. Similar to the partitioning process, the high-level format is specific to the file system you've chosen to use on the drive. On Windows 9x and DOS systems, the primary function of the high-level format is to create a FAT and a directory system on the disk so the operating system can manage files. You must run FDISK before formatting a drive. Each drive letter created by FDISK must be formatted before it can be used for data storage. As you learned in the section "Drive Partitioning and Formatting with Disk Management," Windows 2000 and Windows XP perform the high-level format with the New Partition Wizard.

Usually, you perform the high-level format with the FORMAT.COM program or the formatting utility in Windows 9x/Me Explorer. FORMAT.COM uses the following syntax:

```
FORMAT C: /S /V
```

This command high-level formats drive C:, writes the hidden operating system files in the first part of the partition, and prompts for the entry of a volume label to be stored on the disk at the completion of the process.

The FAT high-level format program performs the following functions and procedures:

1. Scans the disk (read-only) for tracks and sectors marked as bad during the LLF, and notes these tracks as being unreadable.
2. Returns the drive heads to the first cylinder of the partition, and at that cylinder (Head 1, Sector 1) writes a DOS volume boot sector.
3. Writes a FAT at Head 1, Sector 2. Immediately after this FAT, it writes a second copy of the FAT. These FATs are essentially blank except for bad-cluster marks noting areas of the disk that were found to be unreadable during the marked-defect scan.
4. Writes a blank root directory.
5. If the /S parameter is specified, copies the system files, **I.O. SYS** and **MSDOS. SYS** (or **IBMBIO. COM** and **IBMDOS. COM**, depending on which DOS you run), and **COMMAND. COM** to the disk (in that order).
6. If the /V parameter is specified, prompts the user for a volume label, which is written as the fourth file entry in the root directory.

Now, the operating system can use the disk for storing and retrieving files, and the disk is a bootable disk.

During the first phase of the high-level format, the program performs a marked defect scan. Defects marked by the LLF operation show up during this scan as being unreadable tracks or sectors. When the high-level format encounters one of these areas, it automatically performs up to five retries to read these tracks or sectors. If the unreadable area was marked by the LLF, the read fails on all attempts.

After five retries, the DOS FORMAT program gives up on this track or sector and moves to the next one. If an area remains unreadable after the initial read and five retries, it is marked in the FAT as a bad cluster.

Note

Because the high-level format doesn't overwrite data areas beyond the root directory of the hard disk, using programs such as Norton Utilities to unformat the hard disk that contains data from previous operations is possible, provided no programs or data has been copied to the drive after high-level formatting. Unformatting can be performed because the data from the drive's previous use is still present.

If you create an extended partition, the logical DOS drive letters found there need a simpler **FORMAT** command because system files aren't necessary for example, **FORMAT D: /V** for drive D:, **FORMAT E: /V** for drive E:, and so on.

FDISK and FORMAT Limitations

The biggest problem with FDISK is that it is destructive. If you change your mind about disk structure, you must back up your system and start over again. That alone is cause for using FDISK with care, but here are other limitations you should keep in mind:

- FDISK doesn't provide any help with issues of drive letter changes.
- FDISK requires FORMAT before the drive is ready for use.
- FORMAT must check the entire drive before making it ready for use. Its error management is rudimentary and can waste a lot of disk space with older drives that have disk errors.
- FDISK and FORMAT are designed for a single operating system environment, with no provision for multiboot options (Windows 9x and NT or Windows 9x and Linux, for example).
- FDISK and FORMAT offer no procedure for migrating data to a new drive, and the **XCOPY** command is tricky to use.
- FDISK and FORMAT might cause conflicts with existing CD-ROM drives, which often use the next available drive letter after the existing hard drive.

Although Disk Management in Windows 2000 and Windows XP does a better job than FDISK/FORMAT of avoiding drive letter conflicts with existing drives, it's still a destructive process if you need to change your disk partitions, and it has no provision for migrating data.

For these reasons, many drive vendors offer some type of automatic disk installation software with their hard drives. These routines can make the task of disk migration a fast, easy, and reliable operation.

Typical features of automatic disk installation programs include the following:

- *Replacement for FDISK and FORMAT.* A single program performs both functions more quickly than FDISK and FORMAT separately.
- *Database of drive jumpers for major brands and models.*
- *Drive copy function.* Copies contents of old MS-DOS or Windows 9x drive to the new drive, retaining long filenames, file attributes, and so on.
- *CD-ROM drive letter relocation utility.* Moves CD-ROM to new drive letter (to make room for new hard drive letters) and resets Windows Registry and INI file references to new drive letter so CD-ROM software works without reinstallation.
- *Menu-driven or wizard-driven process for installing new hard drive.*
- *Optional override of BIOS limitations for installation of large hard drives (>504MB, 2.1GB, 8.4GB, and so on).*

The two major vendors in the automated disk-utility business are Ontrack Data Recovery, Inc., and StorageSoft (now a part of Phoenix). These companies sell their disk-installation products to OEM hard drive vendors for use with particular brands of drives. They also sell to the public "generic" versions that can be purchased for use with any brand or model of hard disk. [Table 12.4](#) provides a basic overview of the most popular disk-installation programs.

Table 12.4. Overview of Automatic Disk-Installation Programs

Vendor	Software	OEM	Retail
--------	----------	-----	--------

Ontrack	Disk Manager ^[1]	Yes	Yes
StorageSoft ^[2]	DriveGuide	Yes	No
Western Digital ^[3]	Data Lifeguard	Yes	No
Seagate ^[4]	DiscWizard	Yes	No
Maxtor ^[5]	MaxBlast	Yes	No

^[1] *Disk Manager v4.xx and newer have replaced Disk Manager DiskGo!*

^[2] *Phoenix Technologies acquired StorageSoft in 2002.*

^[3] *Data Lifeguard includes a customized version of StorageSoft's EZ-Drive and DriveGuide tools.*

^[4] *Seagate's DiscWizard was codeveloped with Ontrack and contains Ontrack Disk Manager. It is designed for installation of an additional drive. To install the first drive in a new system, download DiscWizard Starter Edition. DiscWizard Online is an online version of DiscWizard 2002.*

^[5] *Maxtor's MaxBlast Plus II is a customized version of DriveGuide. MaxBlast! Software v9.x is a customized version of EZ-Drive. Versions 7.x and 8.x of MaxBlast! are customized versions of Ontrack Disk Manager.*

Disk Manager and EZ-Drive are DOS-based utility programs, whereas DiscWizard, MaxBlast, and Disk Manager version 4.x offer a Windows-like interface. Seagate's DiscWizard and MaxBlast actually analyze the system, ask the user questions about the intended installation, and prepare a customized procedure based on the user's responses.

OEM versions of disk-installation programs are available from the drive makers' websites; retail versions of Disk Manager v4.x usable with any combination of drives can be purchased from retail stores or at the vendor's online store.

Replacing an Existing Drive

Previous sections discussed installing a single hard drive or adding a new hard drive to a system. Although formatting and partitioning a new hard disk can be challenging, replacing an existing drive and moving your programs and files to it can be a lot more challenging.

Drive Migration for MS-DOS Users

When MS-DOS 6.x was dominant, many users used this straightforward method to transfer the contents of their old hard drive to their new hard drive:

1.

The user creates a bootable disk containing FDISK, FORMAT, and XCOPY.

2.

The new hard drive is prepared with a primary partition (and possibly an extended partition, depending on the user's desires).

3.

The new hard drive is formatted with system files, although the operating system identifies it as D:.

4.

The **XCOPY** command is used to transfer all nonhidden files from C:\ (the old hard drive) to D:\, thus:

```
XCOPY C: \ D: \ /S /E
```

The **XCOPY** command also is used as necessary to transfer files from any remaining drive letters on the old hard drive to the corresponding drive letters on the new drive.

Because the only hidden files such a system would have were probably the operating system boot files (already installed) and the Windows 3.1 permanent swap file (which could be re-created after restarting Windows), this "free" data transfer routine worked well for many people.

After the original drive was removed from the system, the new drive would be jumpered as master and assigned C:. The user then would need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. Then, the user would exit FDISK and the drive would boot.

Drive Migration for Windows 9x/Me Users

Windows 9x/Me have complicated the once-simple act of data transfer to a new system by their frequent use of hidden files and folders (such as **\Windows\Inf**, where Windows 9x hardware drivers are stored). The

extensive use of hidden files was a major reason for a greatly enhanced version of XCOPY being included in Windows 9x/Me.

Note

XCOPY32 is automatically used in place of XCOPY when XCOPY is started within a command prompt session under Windows.

XCOPY32 for Windows 9x Data Transfer

Compared to "classic" XCOPY, XCOPY32 can copy hidden files; can preserve file attributes such as system, hidden, read-only, and archive; can automatically create folders; and is compatible with long filenames. Thus, using it to duplicate an existing drive is possible, but with these cautions:

- The **XCOPY32** command is much more complex.
- Errors might occur during the copy process because of Windows's use of temporary files during normal operation, but XCOPY32 can be forced to continue.

This command line calls XCOPY32 and transfers all files and folders with their original attributes intact from the original drive (C:) to the new drive (D:). This command, however, must be run from an MS-DOS prompt window (and not MS-DOS Mode) under Windows 9x/Me, as follows:

```
xcopy32 c:\. d:\ /e/c/h/r/k
```

The command switches are explained here:

- **/e**. Copies folders, even if empty; also copies all folders beneath the starting folder.
- **/c**. Continues to copy after errors. The Windows swap file can't be copied due to being in use.
- **/h**. Copies hidden and system files.
- **/r**. Overwrites read-only files.
- **/k**. Preserves file attributes.

Repeat the command with appropriate drive-letter changes for any additional drive letters on your old drive.

After the original drive is removed from the system, the new drive must be jumpered as master (or single), and the operating system assigns it C:. You next need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. Then, exit FDISK, and the drive will boot.

Note that although the XCOPY method has worked for me, some people have problems with it. A much more automated and easy approach to cloning drives is to use commercial software designed for that purpose, such as PartitionMagic Drive Copy or Norton Ghost by Symantec. Drive copying programs included with older versions of hard disk installation programs provided by drive vendors have not always worked well, but the latest versions of these programs can be very useful for drive copying and other preparation tasks. In recent installations, I've found that the Maxtor MaxBlast disk copying program worked perfectly in transferring a Windows XP installation to a much larger target drive. So, I recommend you try the drive vendor's copying program first. If you have problems, you can use a third-party product instead.

Even though many users have prepared new hard drives for use with nothing but FDISK and FORMAT, today's more complex systems are presenting increasingly good reasons for looking at alternatives.

Hard Disk Drive Troubleshooting and Repair

If a hard drive has a mechanical problem inside the sealed head disk assembly (HDA), repairing the drive is usually unfeasible. It might be doable, but purchasing a new drive will be far less expensive. If the failure is in the logic board, that board can be replaced with one from a donor drive. Typically, this is done only for the purposes of reading the information on the failed drive because you must purchase a complete second drive to cannibalize for the logic board. The drive manufacturers usually don't sell spare parts for their drives anymore.

Most hard disk drive problems are not mechanical hardware problems; instead, they are "soft" problems that can be solved by a new LLF and defect-mapping session. Soft problems are characterized by a drive that sounds normal but produces various read and write errors.

Hard problems are mechanical, such as when the drive sounds as though it contains loose marbles. Constant scraping and grinding noises from the drive, with no reading or writing capability, also qualify as hard errors. In these cases, an LLF is unlikely to put the drive back into service. If a hardware problem is indicated, first replace the logic-board assembly. You can make this repair yourself and, if successful, you can recover the data from the drive.

If replacing the logic assembly does not solve the problem, contact the manufacturer or a specialized repair shop that has clean-room facilities for hard disk repair. (See the Vendor's List on the accompanying disc for a list of drive manufacturers and companies that specialize in hard disk drive repair.) However, because of the costs, simply purchasing a new drive is probably more economical.

Testing a Drive

When accessing a drive, determining whether the drive has been partitioned and formatted properly is easy. A simple test can tell you whether a stored drive is in its "raw" condition or has been partitioned and formatted properly. These tests work best if you have a boot disk available and if the spare hard drive is the only hard drive attached.

First, attach the drive to your system. If you can attach power and data cables to it, you need not install it into a drive bay unless you are planning to use it immediately. If the drive will be run loose, I recommend placing it on a nonconductive foam pad or other soft surface. This insulates the drive from potential shocks and other hazards. After detecting the drive in the BIOS and saving the changes, start your operating system from the boot disk.

Then, from the **A:** prompt, enter the following command:

DIR C:

This produces one of the following responses:

- *Invalid drive specification.* This indicates the drive does not have a valid partition (created by FDISK) or that the existing Master Boot Sector or partition tables have been damaged. No matter what, the drive must be partitioned and formatted before use. You also get this warning on a FAT32 or NTFS partitioned drive if you use a Windows 95 (original version) or MS-DOS boot disk when

checking. Use a Windows 95B, Windows 98/Me, or Windows 2000 boot disk to avoid this false message from FAT32 partitions. Or, use a Windows NT, Windows 2000, or Windows XP boot disk to detect NTFS partitions.

- *Invalid media type*. This drive has been partitioned but not FORMATted, or the format has been corrupted. You should use FDISK's #4 option to examine the drive's existing partitions and either delete them and create new ones or keep the existing partitions and run FORMAT on each drive letter.
- *Directory of C:*. The contents of the C: drive are listed, indicating the drive was stored with a valid FDISK and FORMAT structure and data.

Tip

If you know to which computer the drive was previously connected, you should connect the drive to that computer to perform the test. If you move the drive to another computer, differences in BIOS and ATA host adapter translation could cause a working drive with data to appear to be empty. This is particularly the case with systems that have onboard Promise ATA RAID controllerseven if the ATA RAID feature is not used or you move the drive from a system using an Award or AMI BIOS to a system with a Phoenix BIOS.

[< PREVIOUS](#)[NEXT >](#)

Installing an Optical Drive

Installation of a CD-ROM, CD-R, CD-RW, DVD-ROM, or rewriteable DVD drive can be as difficult or as easy as you make it. If you plan ahead, the installation should go smoothly.

This section walks you through the installation of a typical internal (SCSI or ATA) and external (SCSI only) optical drive, with tips that often aren't included in the manufacturers' installation manuals. After you install the hardware, your job might be finished if you are running Windows and using a Plug and Play drive, or you might have to manually load the software necessary to access the drive.

Note

CD-ROM and DVD-ROM drives use the same ATA, SATA, and SCSI system interfaces and can be installed using the same basic procedures. Some DVD-ROM drives come with an MPEG-2 decoder board or MPEG decoder software that enables you to view DVD movies and video on your PC. If a board is included, it usually installs in a PCI bus slot like any other expansion card and performs the video decoding process that would otherwise fall to the system processor. Software decoding does not require a board and instead uses your processor to do the decoding work. Software decoding normally requires a fast processor (see the software manufacturer's recommendations for how fast); otherwise, the video appears jumpy, jerky, or unsynchronized with the sound. Although many premium DVD setups have included hardware decoding for this reason in the past, today's computers typically have 1GHz and faster processors to make software playback smooth. Also, many video cards now feature onboard DVD hardware decoding, eliminating the need for a separate DVD decoder.

Note that a separate analog or digital audio connection typically exists between the drive and the sound card as well, used primarily for playing audio CDs.

Avoiding Conflict: Get Your Cards in Order

Regardless of the type of installation—internal or external drive—you must have a functioning ATA or SCSI host adapter before the drive can function. In most cases, you will be connecting the optical drive to an existing ATA or SCSI adapter. If so, the adapter should already be configured not to conflict with other devices in your system. All you have to do is connect the drive with the appropriate cable and proceed from there.

Most computers today have an ATA adapter integrated into the motherboard. However, if you are adding SCSI to your system for the first time, you must install a SCSI host adapter into an expansion slot and ensure it is configured to use the appropriate hardware resources, such as the following:

- IRQ
- DMA channel
- I/O port address

As always, Windows 9x/Me/2000/XP and PnP hardware can completely automate this process; however, if you're using another operating system, you might have to configure the adapter manually.

Drive Configuration

Configuration of your new optical drive is paramount to its proper functioning. Examine your new drive and locate any jumpers (see [Figure 12.11](#)). For an ATA drive, here are the typical ways to jumper the drive:

- As the primary (master) drive on the secondary ATA connection
- As the secondary (slave) drive to a current hard disk drive
- Using Cable Select (CS), where the cable connector determines which drive is master or slave automatically

Figure 12.11. The rear connection interfaces of a typical ATA internal CD-ROM drive.

If the drive is to be the only device on your secondary ATA interface, the factory settings are usually correct. Consult the manual to make sure this is so.

When you use the CD-ROM or DVD-ROM as a secondary drivethat is, the second drive on the same ribbon cable with another devicebe sure it is jumpered as the slave drive, and configure the other device so it is the master drive (see [Figure 12.12](#)). In most cases, the drive shows up as the next logical drive, or the D: drive.

Figure 12.12. An embedded ATA interface with primary and secondary ATA

connections (the pen is pointing to the primary ATA connector).

Caution

Whenever possible, you should not connect a CD-ROM or DVD-ROM drive to the same channel as a hard disk drive because devices on the same channel can't simultaneously read or write data. If your computer has the two ATA channels standard in systems today, you should connect the optical drive to the secondary channel, even if you have only one hard disk drive on the primary.

◀◀ These procedures are covered in "[Parallel ATA](#)," p. [559](#).

Depending on how you look at it, SCSI drives can be a bit easier to configure because you need only to select the proper SCSI ID for the drive. By convention, the boot disk (the C: drive) in a SCSI system is set as ID0, and the host adapter has an ID of 7. You are free to choose any ID in between that is not being used by another device. Most SCSI devices use some type of rotating or pushbutton selector to cycle between the SCSI IDs, but some might use jumpers.

SCSI devices are cabled together in a bus configuration. If your new SCSI drive falls at the end of the SCSI bus, you also must terminate the drive. Note that the SCSI bus refers to the physical arrangement of the devices, and not the SCSI IDs selected for each one.

External (SCSI) Drive Hookup

Unpack the drive carefully. With the purchase of an external drive, you should receive the following items:

- CD-ROM or DVD-ROM drive
- SCSI adapter cable

With the exception of the SCSI host adapter, this is the bare minimum you need to get the drive up and running. You'll probably also find a CD caddy, documentation for the drive, driver software, a SCSI terminator plug, and possibly a sampling of CDs to get you started. SCSI drives almost never come with the SCSI host adapter necessary to connect them to the system. Because SCSI is designed to support up to 7 devices on the same system (or up to 15 devices for Ultra2 SCSI), including a host adapter with every peripheral is impractical. Although a few computers have SCSI interfaces integrated into the motherboard, in most cases you have to purchase a SCSI adapter as a separate expansion card.

To begin the installation, take a look at your work area and the SCSI cable that came with the drive. Where will the drive find a new home? You're limited by the length of the cable. Find a spot for the drive, and insert the power cable into the back of the unit. Be sure you have an outlet or, preferably, a free socket in a surge-suppressing power strip to plug in the new drive.

SCSI devices generally use one of two cable types. Some older drives use a 50-pin Centronics cable, referred to as an A-cable. Most drives today, though, use a 68-pin cable called a P-cable. Plug one end of the supplied cable into the connector socket of the drive and one into the SCSI connector on the adapter card. Most external drives have two connectors on the back; either connector can be hooked to the PC (see [Figure 12.13](#)). You use the other connector to attach another SCSI device or, if the drive is at the end of the bus, to connect a terminator plug. Secure the cable with the guide hooks on both the drive and adapter connectors, if provided.

Figure 12.13. External drive with dual SCSI connectors.

Note

A SCSI device should include some means of terminating the bus, when necessary. The terminator might take the form of a cableless plug you connect to the second SCSI connector on the drive, or the drive might be self-terminating, in which case there should be a jumper or a switch you can set to activate termination.

Finally, your external drive should have a SCSI ID select switch on the back. This switch sets the identification number the host adapter uses to distinguish the drive from the other devices on the bus. The host adapter, by most manufacturers' defaults, should be set for SCSI ID 7, and some (but not all) manufacturers reserve the IDs 0 and 1 for use by hard disk drives. Be sure you set the SCSI ID for the CD-ROM or DVD-ROM drive to any other number 6, 5, or 4, for example. The only rule to follow is to be sure you do not set the drive for an ID that is already occupied by either the adapter or any other SCSI peripheral on the bus.

Internal Drive Installation

Unpack your internal drive kit. You should have the following pieces:

- The drive
- The internal CD-audio cable
- Floppy disks/CD-ROM with device driver software and manual
- Drive rails and mounting screws

Your manufacturer also might have provided a power cable splitter a bundle of wires with plastic connectors on each of three ends. A disc caddy and owner's manual might also be included. If you do not already have

one in the computer, you also will need a SCSI host adapter to connect SCSI peripherals.

Make sure the PC is turned off, and remove the cover from the case. Before installing a SCSI adapter into the PC's expansion bus, connect the SCSI ribbon cable to the adapter card (see [Figure 12.14](#)).

Figure 12.14. Connecting a ribbon cable to a SCSI adapter.

Ribbon Cable and Card Edge Connector

The ribbon cable should be identical on both ends. You'll find a red stripe or dotted line down one side of the outermost edge of the cable. This stripe indicates a pin-1 designation and ensures that the SCSI cable is connected properly to the card and drive. If you're lucky, the manufacturer has supplied a cable with notches or keys along one edge of the connector. With such a key, you can insert the cable into the card and drive in only one way. Unkeyed cables must be hooked up according to the pin-1 designation.

Along one edge of your SCSI adapter is a double row of 50 brass-colored pins. This is the card edge connector. In small print along the base of this row of pins you should find at least two numbers next to the pins 1 and 50. Aligning the ribbon cable's marked edge over pin 1, carefully and evenly insert the ribbon cable connector.

Next, insert the adapter card into a free bus slot in the computer, leaving the drive end of the cable loose for the time being.

Choose a bay in the front of your computer's case for your internal drive. Make sure it's easily accessible from the outside and not blocked by other items on your desk. You'll be inserting the CDs or DVDs here, and you'll need the elbow room.

Remove the drive bay cover from the computer case. You might have to loosen some screws to do this, or the cover might just pop off. Inside the drive bay, you should find a metal enclosure with screw holes for mounting the drive. If the drive has mounting holes along its side and fits snugly into the enclosure, you won't need mounting rails. If it's a loose fit, however, mount the rails along the sides of the drive with the rail screws, and then slide the drive into the bay. Secure the drive into the bay with four screws two on each side. If the rails or drive don't line up evenly with four mounting holes, be sure you use at least two screws one mounting screw on each side. Because you'll be inserting and ejecting many discs over the years, mounting the drive securely is a must.

Once again, find the striped side of the ribbon cable and align it with pin 1 on the drive's edge connector. Either a diagram in your owner's manual or a designation on the connector itself tells you which is pin 1.

The back of the drive has a four-pin power connector outlet. Inside the case of your PC, at the back of your floppy or hard disk, are power cords bundled red and yellow wires with plastic connectors on them. You might already have a power connector lying open in the case. Take the open connector and plug it into the back of the power socket on the CD-ROM or DVD-ROM drive. These connectors can go in only one way. If you do not have an open connector, use a drive power splitter (refer to [Figure 12.5](#)). Disconnect an existing drive power cord from the device that uses the least power. Next, attach the splitter to the detached power cord. Plug one of the free ends back into the drive you removed the power from and plug the other into the CD-ROM or DVD-ROM drive.

Note

It's preferable to "borrow" power from the drive that consumes the least power so you don't overload the connection. Check the specification sheets for your drives to determine their power consumption. In general, devices that are physically smaller or that spin more slowly draw less power. If you have no choice if the splitter and ribbon cable won't reach, for example you can split off any power cord that hasn't already been split. Check the power cable to ensure that you have a line not already overloaded with another splitter.

Do not replace the PC cover yet you need to make sure that everything is running perfectly before you seal the case. You're now ready to turn on the computer. If everything runs normally, it's time to put that cover back on.

SCSI Chains: Internal, External, or Both

Remember, one of the primary reasons for using the SCSI interface for your CD-ROM or DVD-ROM drive is the capability to connect a string of peripherals from one adapter, thus saving card slots inside the PC and limiting the nightmare of tracking IRQs, DMAs, and I/O memory addresses.

You can add hard drives, scanners, tape backup units, and other SCSI peripherals to this chain (see [Figure 12.15](#)). You must keep a few things in mind, however, and chief among them is SCSI termination.

Figure 12.15. A SCSI chain of devices on one adapter card.

Example One: All External SCSI Devices. Say that you installed your CD-ROM or DVD-ROM drive and added a tape device to the SCSI bus with the extra connector on the back of the optical drive. The first device in this SCSI bus is the adapter card itself. Most modern host adapters are *autoterminating*, meaning they will terminate themselves without your intervention if they are at the end of the bus.

From the card, you ran an external cable to the optical drive, and from the optical drive, you added another cable to the back of the tape unit. You must now terminate the tape unit as well. Most external units are terminated with a SCSI cap or a small connector that plugs into the unused external SCSI connector. These external drive connectors come in two varieties: a SCSI cap and a pass-through terminator. The cap is just that; it plugs over the open connector and covers it. The pass-through terminator, however, plugs into the connector and has an open end into which you can plug the SCSI cable. This type of connector is essential if your external drive has only one SCSI connector; you can plug the drive in and make sure it's terminated all with one connector.

Example Two: Internal Chain and Termination. On an internal SCSI bus, the same rules apply: All the internal devices must have unique SCSI ID numbers, and the first and last devices must be terminated. In the case of internal devices, however, you must check for termination. Internal devices typically have DIP switches or terminator packs similar to those on your adapter card. If you install a tape unit as the last device on the chain, it must have some means of terminating the bus. If you place your optical drive in the middle of the bus, you must deactivate its termination. The host adapter at the end of the chain must still be terminated.

Note

Most internal SCSI devices ship with terminating resistors or DIP switches onboard, usually the

latter. Check your user manuals for their locations. Any given device can have one, two, or even three such resistors.

Example Three: Internal and External SCSI Devices. If you mix and match external as well as internal devices, follow the same rules. The bottom example shown in [Figure 12.16](#) has an internal CD-ROM drive, terminated and set for SCSI ID 6; the external hard drive also is terminated and is using SCSI ID 5. The SCSI adapter itself is set for ID 7 and, most importantly, its termination has been disabled because it is no longer at the end of the bus.

Figure 12.16. Examples of various SCSI termination scenarios.

[\[View full size image\]](#)

Note

As with any adapter card, be careful when handling the card itself. Be sure to ground yourself first.

To help you determine whether your SCSI interface card and devices are functioning properly, Adaptec supplies a utility program called SCSI Interrogator. Use it to determine which logical unit numbers (LUNs) are available for new devices.

If you don't see any devices listed, you might have a termination problem. Shut down your system and your devices. Then, check terminator plugs, switches, or resistor packs. If they appear correct, turn on the external devices about 5 seconds before you start the system. A multiswitch power director with high-quality surge protection works well for this because it allows you to turn on individual devices. If the devices fail to show up after you restart the system, you might have a problem with the SCSI BIOS or device driver software. Check the documentation for your particular card and device to ensure you have installed the proper drivers.

One peculiarity of the Adaptec SCSI Interrogator is that it lists a "host adapter #1" that's actually your ATA interface! If your SCSI card isn't working, both "host adapter #0" and "host adapter #1" are actually ATA. You can tell whether this is happening with Windows 9x because it will list "ESDI_506" as the driver version.

Floppy Drive Installation Procedures

A floppy drive is one of the simplest types of drives to install. In most cases, installing a floppy disk drive is a matter of attaching the drive to the computer chassis or case and then plugging the power and signal cables into the drive. Some type of brackets and screws are usually required to attach the drive to the chassis; however, some chassis are designed to accept the drive with no brackets at all. Any brackets, if necessary, are normally included with the chassis or case itself. Several companies listed in the Vendor List on the accompanying disc specialize in cases, cables, brackets, screw hardware, and other items useful in assembling systems or installing drives.

Note

Because floppy disk drives are generally installed into the same half-height bays as hard disk drives, the physical mounting of the drive in the computer case is the same for both units. See the section "[Hard Disk Installation Procedures](#)," earlier in this chapter, for more information on the process.

When you connect the drive, make sure the power cable is installed properly. The cable is usually keyed so you can't plug it in backward, but the keying can be defeated by somebody forcing the connection. If that is done, the drive will be fried the instant the power is turned on.

Next, install the interface cable. A floppy interface cable is a 34-pin cable that typically has a twist in it. What I mean is that pins 10/16 are twisted around before they reach the last (A:) drive connector. Normally, the A: drive must be plugged in after this twist; any drive plugged into a connector before the twist is seen by the system as drive B: . The twist reverses the drive select and motor enable signals, letting A: and B: drives coexist without rejumping. This is similar to the way Cable Select works for ATA/IDE drives. Because of this, all floppy drives are jumpered the same way, in the second Drive Select (DS) position.

Older drives used to require various jumpers to be set to enable the drive to work properly. The two most common jumpers were the Drive Select jumper and the Disk Change (DC) jumper. If you encounter an older drive with these jumpers, you should follow a few simple rules. The DS jumper typically has two positions, labeled 0 and 1 or in some cases, 1 and 2. In all PC installations, the DS jumper should be set on the second position, no matter what it is numbered. This enables the drive on the cable before the twist to function as drive B: and the drive at the end of the cable after the twist to function as drive A: . The DC jumper setting is normally an on or off setting. For PC use, if the drive has a DC jumper, it must be set on or enabled. This enables the PC to detect when you have changed disks in the drive. For more information on floppy drives and interfacing, see [Chapter 10](#).

The interface cable is usually keyed to prevent backward installation. If no key exists in this cable, use the colored wire in the cable as a guide to the position of pin 1. Normally, pin 1 is oriented closest to the power connector, which is the same as other drives. If the drive LED stays on continuously when you power up the system or when the system is running, that is a sure sign you have the floppy cable on backward either at the drive end or at the controller (motherboard) end.

Chapter 13. Video Hardware

[Video Display Technologies](#)

[Maintaining Your Monitor](#)

[Video Display Adapters](#)

[3D Graphics Accelerators](#)

[Upgrading or Replacing Your Video Card](#)

[Adapter and Display Troubleshooting](#)

Video Display Technologies

Although video display technologies are as vital to a PC's user interface as the mouse and keyboard, the video display is actually a latecomer to computing. Before CRT monitors came into general use, the teletypewriter was the standard computer interface—a large, loud device that printed the input and output characters on a roll of paper.

The first CRT displays used on computers were primitive by today's standards; they displayed only text in a single color (usually green), but to users at the time they were a great improvement, allowing real-time display of input and output data. Over time, color displays were introduced, screen sizes increased, and LCD technologies moved from the portable computer to the desktop. The latest trends, large-screen plasma displays and LCD/DLP projectors, reflect the increasing convergence of entertainment and computer technologies exemplified by developments such as Windows XP Media Center PCs.

Today, PC video displays are much more sophisticated, but you must be careful when selecting video hardware for your computer. A poor display can cause eyestrain or otherwise significantly diminish the experience of using your PC.

The video subsystem of a PC consists of two main components:

- *Monitor (or video display)*. The monitor can be a CRT or an LCD panel for desktop use, or a wide-screen LCD TV, plasma display, or projector using LCD or DLP technology.
- *Video adapter (also called the video card or graphics adapter)*. On many recent low-cost desktop systems and virtually all portable systems, video might be built into the motherboard or included as part of the motherboard's chipset. On a desktop computer, you can add a high-speed AGP or PCI-Express video card to some systems with integrated video.

This chapter explores the range of PC video adapters on the market today and the displays that work with them. The remainder of this section covers the various types of display technologies.

Note

The term *video*, as it is used in this context, does not necessarily imply the existence of a moving image, such as on a television screen. All adapters that feed signals to a monitor or other display are video adapters, regardless of whether they are used with applications that display moving images, such as multimedia or videoconferencing software.

For this reason, video cards are sometimes referred to as *graphics cards* or *display adapters*.

A PC monitor is typically based on one of two display technologies: liquid crystal display (LCD) or cathode-ray tube (CRT). Projectors, on the other hand, are usually based on LCD or digital light processing (DLP) technology. The following sections discuss each type of display technology.

LCD Panels

LCD panels have now largely supplanted CRT displays in new computer installations. That isn't to say CRTs are obsolete far from it. They are now just as common. Desktop LCD panels use technology similar to that of LCDs in laptop computers. Compared to the original display technology (CRTs), LCDs have low-glare, completely flat screens and low power requirements (5 watts versus nearly 100 watts for an ordinary CRT monitor). The color quality of a good active-matrix LCD panel actually exceeds that of most CRT displays, particularly when viewed from head on.

How LCD Displays Work

In an LCD, a polarizing filter creates two separate light waves. The polarizing filter allows light waves that are aligned only with the filter to pass through. After passing through the polarizing filter, the remaining light waves are all aligned in the same direction. By aligning a second polarizing filter at a right angle to the first, all those waves are blocked. By changing the angle of the second polarizing filter, the amount of light allowed to pass can be changed. It is the role of the liquid crystal cell to change the angle of polarization and control the amount of light that passes. The liquid crystals are rod-shaped molecules that flow like a liquid. They enable light to pass straight through, but an electrical charge alters their orientations and the orientation of light passing through them. Although monochrome LCDs do not have color filters, they can have multiple cells per pixel for controlling shades of gray.

In a color LCD, an additional filter has three cells for each pixel—one each for displaying red, green, and blue—with a corresponding transistor for each cell. The red, green, and blue cells that make up a pixel are sometimes referred to as *subpixels*. The ability to control each cell individually has enabled Microsoft to develop a new method of improving LCD text quality. Beginning with Windows XP, you can enable a feature called ClearType through the Display properties sheet. ClearType can dramatically improve the legibility of text onscreen and further reduce eye strain from extended PC use. However, the downside to this technology is that individual cells can fail.

Dead Pixels

A so-called *dead pixel* is one in which the red, green, or blue cell is stuck on or off. Failures in the on state are more common. In particular, those that fail when on are very noticeable on a dark background, such as bright red, green, or blue dots. Although even a few of these can be distracting, manufacturers vary in their warranty policies regarding how many dead pixels are required before you can get a replacement display. Some vendors look at both the total number of dead pixels and their locations. Fortunately, improvements in manufacturing quality make it less and less likely that you will see a screen with dead pixels either on your desktop or in your notebook computer display.

Although there is no normal way to repair bad pixels, there might be a simple fix that can help. I have actually repaired bad pixels by gently tapping on the screen at the pixel location. This seems to work in many cases, especially in cases in which the pixel is always illuminated instead of dead (dark). Because I find a constantly lit pixel to be more irritating than one that is constantly dark, this fix has saved me a lot of aggravation.

Active-Matrix Displays

LCD panels use a type of active-matrix technology known as a thin film transistor (TFT) array. TFT is a method for packaging from one (monochrome) to three (RGB color) transistors per pixel within a flexible material that is the same size and shape as the display. Therefore, the transistors for each pixel lie directly behind the liquid crystal cells they control.

Two TFT manufacturing processes account for most of the active-matrix displays on the market today:

hydrogenated amorphous silicon (a-Si) and low-temperature polysilicon (p-Si). These processes differ primarily in their costs. At first, most TFT displays were manufactured using the a-Si process because it required lower temperatures (less than 400°C) than the p-Si process of the time. Now, lower-temperature p-Si manufacturing processes are making this method an economically viable alternative to a-Si.

To improve horizontal viewing angles in the latest LCDs, some vendors have modified the classic TFT design. For example, Hitachi's in-plane switching (IPS) design also known as STFT aligns the individual cells of the LCD parallel to the glass, running the electric current through the sides of the cells and spinning the pixels to provide more even distribution of the image to the entire panel area. Hitachi's Super-IPS technology also rearranges the liquid crystal molecules into a zigzag pattern, rather than the typical row-column arrangement, to reduce color shift and improve color uniformity. The similar multidomain vertical alignment (MVA) technology developed by Fujitsu divides the screen into different regions and changes the angle of the regions.

Both Super-IPS and MVA provide a wider viewing angle than traditional TFT displays. Other companies have different names for the same technology for example, Sharp calls it Ultra High Aperture (UHA). Manufacturers often like to think up their own buzzwords for the same technology because it makes their products seem different, but the results they generate are all largely the same. Because larger LCDs (17" and wider) are large enough to cause shifts in viewing angle even for an individual user, these advanced technologies are being used primarily on larger and more expensive panels and have been licensed to other display vendors.

LCD Display Sizes and Resolutions

Standard 4:3 ratio LCD panels are available in sizes ranging from 15" up to 23" diagonal measure. LCD screens from 1518.1" in size are usually more limited in resolution than comparably sized CRTs, although LCD displays and CRT displays at larger sizes offer similar resolutions. [Table 13.1](#) compares the typical resolutions of LCD monitors from 15" to 23" to mainstream CRT monitors ranging from 17" to 21" with comparable viewable areas.

Table 13.1. LCD and CRT Resolutions Compared

LCD Size	LCD Resolution	CRT Size	CRT Viewable Area	CRT Maximum Resolution
15"	1024x768	17"	16"	1024x768 1280x1024 1600x1200*
17"	1280x1024			
18.1"	1280x1024	19"	18"	1600x1200 1920x1440*
19"	1280x1024			
20.1"	1600x1200	21"	20"	1600x1200

1920x1440*

2048x1536*

21.3"	1600x1200
-------	-----------

23"	1920x1200
-----	-----------

**Available on high-end monitors only*

As you can see from [Table 13.1](#), you need a 20.1" or larger LCD panel to achieve resolutions above 1280x1024, although most 18" or larger CRT displays can achieve 1600x1200.

Despite recent price drops, LCD panels continue to be more expensive than comparably sized CRTs. The most common sizes of LCD panels today fall into the 17"19" sizes. 17" LCDs typically sell for around \$220\$400, compared to \$120\$200 for 17" CRTs. 19" LCDs typically sell for around \$260\$700, compared to around \$170\$260 for 19" CRTs.

Note

The price ranges given are approximate and reflect mainstream products. Some specialized products, such as wide-screen LCDs or TV/monitor combinations, are more expensive. Wide-screen LCDs designed for TV/monitor use can be as large as 46" diagonal measure.

However, as [Table 13.1](#) shows, it is important to consider that an LCD screen provides a larger viewable image than a CRT monitor of the same size. See [Figure 13.1](#) for an example of a typical desktop LCD panel.

Figure 13.1. Note the small footprint of this 15" LCD, which makes these panels ideal for use in cramped quarters.

Two basic LCD choices are available today on notebook computers: active-matrix analog color and active-matrix digitalthe latest development. Monochrome LCDs are obsolete for PCs, although they remain popular for Palm and similar organizer devices and are sometimes used for industrial display panels. Passive-matrix displays using dual-scan technology were popular for low-cost notebook models until a few years ago, but they have been completely replaced by analog or digital active-matrix displays. Passive-matrix displays are still used with handheld organizers or for industrial-use desktop display panels because of their low cost and enhanced durability compared to active-matrix models.

Note

The most common type of passive-matrix display uses a supertwist pneumatic design, so these panels are often referred to as *STNs*. Active-matrix panels usually use a thin-film transistor design and are thus referred to as *TFTs*.

Benefits of LCD Panels

LCD monitors offer a number of benefits when compared to conventional CRT glass tube monitors. LCD panels feature a larger effective viewable area than CRTs; a 17" LCD is essentially equal in usability to a 19" CRT (refer to [Table 13.1](#)). Because LCDs use direct addressing of the display (each pixel in the picture corresponds with a transistor), they produce a high-precision image. LCDs can't have the common CRT display problems of pincushion, barrel distortion, or convergence errors (halos around the edges of onscreen objects).

LCD panels are less expensive to operate than CRTs because they feature lower power consumption and much less heat buildup than CRTs. Because LCD units lack a CRT, no concerns exist about electromagnetic VLF or ELF emissions. Although LCDs offer a comparable mean time between failures (MTBF) to CRT displays, the major reason for LCD failures is the backlight, which is relatively inexpensive to replace. CRT failures usually involve the picture tube, which is the most expensive portion of the display and is often especially on displays 17" and smaller not cost-effective to replace.

LCD panels offer a smaller footprint (front-to-back dimensions), and some offer optional wall or stand mounting. Several LCD panels offer a pivoting feature, enabling the unit to swivel 90° and providing a choice between the traditional landscape horizontal mode for web surfing and the portrait vertical mode for word processing and page-layout programs. LCD panels weigh substantially less than comparably sized CRTs. For example, the ViewSonic VE175, a 17" LCD, weighs only 13.6 lbs., compared to the 50 lbs. weight of typical 19" CRTs.

LCD Panel Display Connections

Although LCD panels are inherently digital, many computers, particularly low-cost units and those with integrated graphics, lack digital video connections. Therefore, a particular desktop LCD panel might use either a traditional analog VGA connector or a digital DVI connector, or offer both connections. Typically, lower-cost 15"17" LCD panels use the traditional analog VGA connector and must convert analog signals back into digital, whereas more expensive 15"17" and most larger LCD panels provide both the analog VGA and the DVI digital connector found on most high-end and mid-range video cards. Note that some LCD vendors of VGA/DVI-compatible panels might provide only the cheaper analog VGA cable, leaving it to you to buy your own DVI cable. If you plan to connect your new LCD to your video card's DVI port, be sure that the panel supports DVI and that the cable is included. And, while you're shopping for an LCD panel, be sure to note which models include the DVI cable; the presence of a DVI cable in the box of a nominally more expensive display can more than make up the difference in price between it and an apparently less-expensive panel that doesn't include the cable.

►► For more information about VGA ports, see "[The Video Graphics Array Standard](#)," p. [884](#).

DFP and DVI Interfaces for Digital LCD Panels

As I mentioned earlier in this chapter, LCD panels use digital signaling. To avoid converting analog signals from a traditional VGA card or integrated video solution into digital signals, two digital LCD panel standards and specifications have been developed to permit an all-digital connection between the display adapter and the panel:

- *The Digital Flat Panel (DFP) standard approved by the Video Electronic Standards Association (VESA) in February 1999.* DFP was previously known as PanelLink; DFP has now been replaced by DVI.
- *The Digital Visual Interface (DVI) standard proposed by the Digital Display Working Group (DDWG) in April 1999.* DVI has become a de facto standard supported by most recent mid-range and high-end VGA display cards, including models with dual-display capabilities. DVI-D is also known as DVI HDCP. This port is used on many LCD and plasma TVs.

[Figure 13.2](#) shows how DFP and DVI connectors found on some video cards and digital LCDs compare to the standard VGA connector used on conventional video cards, CRTs, and analog-compatible LCDs.

Figure 13.2. Conventional VGA cards, CRTs, and analog-compatible LCDs use the standard VGA connector. Early digital LCDs and their matching video cards often used the DFP connector. Most recent digital LCD panels and LCD TVs use the DVI-D (also known as the DVI-HDCP) connector, whereas video cards used with both analog and digital displays use the DVI-I connector.

[\[View full size image\]](#)

The DVI-I connector shown in [Figure 13.2](#) can be converted into a VGA port for use with CRTs or with analog LCD panels by connecting an adapter, shown in [Figure 13.3](#). Often new graphics cards purchased at retail that support only DVI come with an adapter like this one that allows you to connect a traditional VGA connector from the display to the adapter.

Figure 13.3. Adapting a video card with a DVI-I port to use a VGA cable from a CRT or analog LCD panel.

Wide-screen LCD Panels

Although most LCD panels use the 4:3 (also known as 1.33:1) aspect ratio used by CRTs, an increasing number of LCD panels now feature a 16:10 aspect ratio, similar to the 16:9 aspect ratio used by wide-screen TVs. Wide-screen LCD panels offer many benefits:

- You can watch wide-screen TV programs and movies on DVD with the entire screen area, rather than in letterbox mode as with 4:3 ratio displays.
- Most support digital connections to your PC via the DVI port for greatest picture quality and include component and S-video connections to work with mid-range and high-end DVD and VCR set-top boxes, as well as VGA and composite connections for use with low-end PCs or DVD/VCR units.
- Some support portrait mode for easier document editing.
- You can view more documents onscreen at the same time or increase the magnification level used for detail work on documents and photos.
- There's plenty of room for floating menus, a common feature with photo and video editing programs.

However, you need to ensure that the LCD panel provides sufficient resolution for high-quality computer use. Many wide-screen LCDs in 20" or larger sizes are designed primarily for use as televisions. These units can have resolutions as low as 640x480. A true wide-screen LCD monitor has vertical resolutions similar to a comparably sized 4:3 LCD panel, with proportionally wider horizontal resolutions. For example, a typical 21" wide-screen LCD monitor offers a horizontal resolution of 1680 pixels and a vertical resolution of 1050 pixels. This is comparable to the resolutions provided by a typical 19" 4:3 ratio LCD panel, which features a 1280x1024 resolution. [Table 13.2](#) lists typical resolutions for wide-screen LCD panels and LCD TVs that support PC video inputs (TV/monitors) in sizes from 17" to 32".

Table 13.2. Wide-screen LCD Panel and LCD TV Resolutions

LCD Size	Intended Use	Resolution	Sample Unit
17"	TV/Monitor	1280x768	LG 17LX1R
19"	TV/Monitor	1280x768	Sony WEGA KLVS19A10
20"	TV/Monitor	1366x768	Toshiba 20HL85
20"	Monitor	1680x1050	Apple M9177LL/A
21"	Monitor	1680x1050	Gateway FPD2185W
23"	TV/Monitor	1366x768	Sony WEGA KLVS23A10
23"	Monitor	1920x1200	HP f2304
26"	TV/Monitor	1366x768	Samsung LNR268W
27"	TV/Monitor	1280x720	Westinghouse LTV-27W2
32"	TV/Monitor	1366x768	Sony BRAVIA KLVS32A10

As you can see from [Table 13.2](#), wide-screen LCD panels designed primarily for TV use offer lower resolutions than those designed as monitors.

For more information about display resolution standards, see [Table 13.3](#), p. [869](#).

The resolutions offered by TV/monitor-type panels are satisfactory for watching TV, DVD, and video content and for console gaming, but they are not high enough for detail work. I recommend using a wide-screen LCD monitor if you want a unit optimized for computer use with a secondary use as a TV monitor. If you buy an LCD panel designed for TV use, I recommend that you use it as an additional monitor, not as your primary monitor.

Note

LCD TVs have built-in TV tuners, and some also feature built-in HDTV tuners. If you want to watch TV on an LCD monitor, you need to use an external tuner, such as a TV tuner card, a video card with integrated TV support (cards based on the ATI All-in-Wonder or NVIDIA Personal Cinema series offer TV support), or a set-top TV tuner with suitable connections.

Potential Drawbacks of LCD Panels

Many users are replacing their CRT displays with LCD panels or using a mixture of CRT and LCD displays. As the industry continues to move to LCD panels, there are some potential drawbacks to consider:

- *If you routinely switch display resolutions (as web developers do to preview their work), LCD monitors must take one of two approaches to change resolutions.* Some older units might reduce the onscreen image to occupy only the pixels of the new resolution, thus using only a portion of a typical 1024x768 LCD panel to display a 640x480 image, whereas newer units might scale the image to occupy the entire screen. Although scaling is common on recent displays, some displays provide better-quality scaling than others. Typically, though, a CRT can handle a wider range of resolutions than an LCD.
- *If you choose an analog LCD panel, you'll usually save money and be able to use your existing video card or onboard video port.* However, image quality for both text and graphics can suffer because of the conversion of the computer's digital signal to analog (at the video card) and back to digital again (inside the LCD panel). The conversion can lead to pixel jitter or pixel swim, in which adjacent LCD cells are turned on and off by the display's incapability to determine which cells should stay on and stay off. Most panels come with adjustment software to reduce this display-quality problem, but you might not be able to eliminate it entirely.
- *Digital LCD panels avoid conversion problems when attached to a digital-compatible display card.* However, most low-cost, off-the-shelf display cards don't support digital signals yet, and the onboard video circuits built in to some motherboards don't support DVI yet.

Note

Although most recent video chipsets made by NVIDIA, ATI, and Matrox include support for digital and analog display panels, low-cost video cards often omit the DVI connector or don't provide a DVI/VGA adapter. Check the specifications for a particular video card to verify support for the display type you want to use.

- *High-quality LCD panels of either digital or analog type are great for displaying sharp text and graphics.* But they sometimes can't display as wide a range of very light and very dark colors as CRTs can.
- *Many LCDs don't react to changes in the images being displayed as quickly as CRTs.* This can cause full-motion video, full-screen 3D games, and animation to look smeared onscreen. To avoid this problem, look for LCDs that offer a response time of 16ms or faster. Some LCDs now have response times under 10ms. These displays use an improved control method called feed forward driving (FFD) technology developed by Mitsubishi.

Note

Instead of applying the same voltage level to LCD cells when the image changes, FFD uses the optimum voltage level for each cell when it changes. Because cells require different voltage levels depending on the shade needed, FFD displays reduce blur by improving display performance. FFD displays first became available at retail late in 2002, but low-cost LCDs might not use this technology yet. Be sure to check the response time for a particular panel if you want to use it for gaming, video editing, or viewing DVDs or TV.

Shopping Criteria for LCD Panels

Thanks to price decreases, larger panel sizes, improved performance, and widespread support for DVI digital connectors on current video cards, this is the best time ever to consider buying an LCD panel for your desktop PC.

Be sure that you use the following criteria when you consider purchasing an LCD monitor:

- *Evaluate the panel both at its native resolution and at any other resolutions you plan to use.* This is especially important for web design, games, and video editing.
- *If you're considering a digital LCD panel, determine whether your existing video card or onboard video supports the features you need.* You might need to upgrade to a PCI-Express (or AGP) video card that features a DVI port because many low-cost systems with integrated video or low-end video cards don't have a DVI port. For maximum flexibility without upgrading existing video while preserving the ability to move to digital display support later, consider a display that features both analog and digital connectors.
- *Look for displays that support both analog and DVI inputs if you want to use the same display on different systems.* Because LCD panels are much lighter and smaller than normal CRT displays, they're a natural choice for connecting to both desktop and notebook computers. If you use multiple computers in a small work area, you might also want to look for displays that support multiple inputs, which enables you to connect two computers to one screen.
- *Make sure your system has a suitable expansion slot for the recommended video card type.* Many low-cost systems feature onboard AGP or PCI-Express video but no AGP or PCI-Express slot, which can't be upgraded unless the user opts for the obsolescent (for video) PCI slot. As the move to LCD panels continues, more of these systems should feature built-in support for LCDs, but this could be a problem for some time to come.

Note

Although many recent chipsets with integrated video feature DVI support, most motherboards using these chipsets do not provide a built-in DVI port. Instead, an optional add-on card that plugs in to the AGP or PCI-Express slot (if present) is used to enable DVI support. Otherwise, the onboard video can be disabled and replaced with a dual-display video card with VGA and DVI ports.

- *Evaluate the panel and card combo's performance on video clips and animation if you work with full-motion video, animated presentation programs, or games.* Look for response times of 16ms or faster for best results.
- *Although active-matrix (analog) and digital LCD monitors have much wider viewing areas than do passive-matrix and dual-scan LCD panels used in older notebook computers, their viewing angles are still usually much less than CRTs.* This is an important consideration if you're planning to use your LCD monitor for group presentations. To improve the horizontal viewing area, several vendors have developed patented improvements to the basic TFT display, such as Hitachi's in-plane switching (IPS), Fujitsu's multidomain vertical adjustment (MVA), and Mitsubishi's FFDall of which have been licensed to other leading LCD makers. By using such improvements, as well as increased contrast ratios, horizontal viewing angles exceeding 170° have been achieved in some recent designs.
- *A high-contrast ratio (luminance difference between white and black) makes for sharper text and vivid colors.* A typical CRT has a contrast ratio of about 245:1. Some recent LCD panels have contrast ratios as high as 500:1 or more. Higher contrast ratios help improve horizontal viewing angles and improve the appearance of movies and TV shows.
- *Features such as integrated speakers and Universal Serial Bus (USB) hubs are pleasant additions,*

but your eyes should make the final decision about which panel is best for you. Because reviews of LCD panels often don't provide detailed analysis of horizontal and vertical viewing angles and contrast ratios, check display units in stores yourself. Be sure to view the displays from several angles. If you're adding the panel as a second display, be sure to check its off-axis image quality.

- *Look for pivoting displays that enable you to rotate the display to match an upright page layout if you use your computer for text-editing or page layout.* This feature is supported by many LCD panels particularly those that are 17" or larger but the display performance in portrait mode is usually lower than in normal landscape mode, especially for rapid motion. If possible, test the display in portrait mode if you plan to use this mode frequently.

How CRT Display Technology Works

The original display technology (CRT) is the same technology used in television sets. In the last couple of years, CRTs have become scarce on store shelves, although they still have some advantages over LCDs.

CRTs consist of a vacuum tube enclosed in glass. One end of the tube contains an electron gun assembly that projects three electron beams, one each for the red, green, and blue phosphors used to create the colors you see onscreen; the other end contains a screen with a phosphorous coating.

When heated, the electron gun emits a stream of high-speed electrons that are attracted to the other end of the tube. Along the way, a focus control and deflection coil steer the beam to a specific point on the phosphorous screen. When struck by the beam, the phosphor glows. This light is what you see when you watch TV or look at your computer screen. Three layers of phosphors are used: red, green, and blue. A metal plate called a *shadow mask* is used to align the electron beams; it has slots or holes that divide the red, green, and blue phosphors into groups of three (one of each color). Various types of shadow masks affect picture quality, and the distance between each group of three (the *dot pitch*) affects picture sharpness.

See "[Dot Pitch \(CRTs\)](#)," p. [871](#).

[Figure 13.4](#) illustrates the interior of a typical CRT.

Figure 13.4. A typical CRT monitor is a large vacuum tube. It contains three electron guns (red, green, and blue) that project the picture toward the front glass of the monitor. High voltage is used to produce the magnetism that controls the electron beams that create the picture displayed on the front of the CRT.

[\[View full size image\]](#)

The phosphor chemical has a quality called *persistence*, which indicates how long this glow remains onscreen. Persistence is what causes a faint image to remain on your TV screen for a few seconds after you turn off the set. The scanning frequency of the display specifies how often the image is refreshed. You should have a good match between persistence and scanning frequency so the image has less flicker (which occurs when the persistence is too low) and no ghost images (which occurs when the persistence is too high).

The electron beam moves very quickly, sweeping the screen from left to right in lines from top to bottom, in a pattern called a *raster*. The horizontal scan rate refers to the speed at which the electron beam moves laterally across the screen.

During its sweep, the beam strikes the phosphor wherever an image should appear onscreen. The beam also varies in intensity to produce different levels of brightness. Because the glow begins to fade almost immediately, the electron beam must continue to sweep the screen to maintain an image a practice called *redrawing* or *refreshing* the screen.

Most current CRT displays have an ideal refresh rate (also called the vertical scan frequency) of about 85 hertz (Hz), which means the screen is refreshed 85 times per second. Refresh rates that are too low cause the screen to flicker, contributing to eyestrain. The higher the refresh rate, the better for your eyes. Lowcost monitors often have flicker-free refresh rates (72Hz or higher) available only at 640x480 and 800x600 resolutions; you should insist on high refresh rates at resolutions such as 1024x768 or higher.

Tip

I use the 72Hz refresh rate (the minimum flicker-free refresh rate) as a shortcut for determining the highest usable resolution for a CRT. Many CRTs offer a maximum resolution that supports refresh rates lower than 72Hz. Because low refresh rates cause flicker and eyestrain, I won't use them. For example, a 17" monitor might offer a maximum refresh rate of 1280x1024 at 66Hz and a 1024x768 mode at 87Hz. As far as I'm concerned, that monitor has a usable maximum resolution of 1024x768.

It is important that the refresh rates expected by your monitor match those produced by your video card. If you have mismatched rates, you will not see an image and can actually damage your monitor. Generally speaking, video card refresh rates cover a higher range than most monitors. For this reason, the default refresh rate used by most video cards is relatively low (usually 60Hz) to avoid monitor damage. The refresh rate can be adjusted through the Windows display properties sheets.

Multiple Frequency Monitors

Although a few very old monitors had fixed refresh rates, virtually all monitors in use support a range of frequencies. This support provides built-in compatibility with a wide range of current and future video standards (described in the "[Video Display Adapters](#)" section later in this chapter). A monitor that supports many video standards is called a *multiple-frequency monitor*. Virtually all monitors sold today are multiple frequency, which means they support operation with a variety of popular video signal standards. Different vendors have used a variety of trade names to identify their multiple-frequency monitors, including multisync, multifrequency, multiscan, autosynchronous, and auto-tracking, among others.

Note

Even though a monitor is capable of displaying a wide range of video standards, you usually need to fine-tune the display through its onscreen display (OSD) controls and Windows display properties sheets to achieve the best possible pictures.

Curved Versus Flat Picture Tubes

Phosphor-based screens come in two styles: curved and flat. Until recently, the typical display screen has been curved; it bulges outward from the middle of the screen. This design is consistent with the vast majority of CRT designs (the same as the tube in most television sets). Although this type of CRT is inexpensive to produce, the curved surface can cause distortion and glare, especially when used in a brightly lit room. Some vendors use antiglare treatments to reduce the reflectivity of the typical curved CRT surface.

The traditional screen is curved both vertically and horizontally. Some monitor models use the Sony Trinitron CRT, some versions of which are curved only horizontally and flat vertically; these are referred to as *flat square tube (FST)* designs.

Virtually all manufacturers have switched their remaining CRT monitor product lines to CRTs that are flat both horizontally and vertically. Sony's FD Trinitron, NEC-Mitsubishi's DiamondTron NF, and ViewSonic's

PerfectFlat are some of the more popular flat CRT designs. Many people prefer this type of flatter screen because these picture tubes show less glare and provide a higher-quality, more accurate image. Although flat-screen CRTs are slightly more expensive than conventional curved CRTs, they are only one-third to one-half the price of comparably sized flat-panel LCDs.

[Figure 13.5](#). compares the cross-section of typical curved and flat CRT picture tubes.

Figure 13.5. A typical curved-tube CRT (left) compared to a Sony FD Trinitron flat tube (right).

CRT Interfaces

Most CRTs are designed to connect to the traditional 15-pin VGA port, although a few high-end models also support BNC connections for use with other types of video sources. A few CRTs in the past have used DVI ports, but DVI never caught on as a video source for CRTs and these monitors have been discontinued.

►► For VGA port pinouts, see "[The Video Graphics Array Standard](#)," p. [884](#).

CRT Versus LCD Displays

Until recently, CRT displays were the leading display type. However, most stores now stock far more LCD panels than CRTs, and some monitor vendors no longer manufacture CRTs. There are, however, benefits to sticking with a CRT monitor, including

- *Widest viewing angle without color distortion.* If you plan to use a monitor, rather than a projector, to show a presentation to a small group, a monitor provides accurate color rendition and image details to anyone who can see the screen, even at a significant angle from a straight-on view. Although recent LCD displays offer wider viewing angles (up to 170° or more horizontal and up to 120° vertical), a CRT is still superior for enabling everyone to see a presentation.
- *Lower initial cost.* Although 15" LCD displays are often comparable in price to 17" CRTs (and offer comparable viewing areas), you will save a lot of money up-front if you buy a 19" or larger CRT versus an LCD panel.
- *Resolution flexibility.* Although late-model LCD panels offer greater quality when used at non-native resolutions, high-quality CRTs still rule if you need support for a wide range of resolutions. Keep in mind that you will need to fine-tune each resolution and refresh rate combination using your monitor's onscreen display (OSD) controls the first time you use a particular combination. The monitor's nonvolatile RAM will remember your settings and apply them the next time you enter that mode.
- *Response time.* Even a low-cost CRT offers an instant, ghost-free response time when playing back full-motion video or when playing games when you select the recommended refresh rate for the resolution (72Hz/85Hz). However, if you use an LCD panel, you must ensure that the panel supports response times of 16ms or faster. Many low-cost LCD panels offer slower response times.

Caution

The lower initial cost of a large CRT can be offset by higher shipping costs if you order by mail or over the Internet. CRTs are expensive to ship because of their bulk and weight. If possible, buy your CRT monitor locally to avoid the additional cost of shipping.

LCD and DLP Projectors

Originally, data projectors were intended for use in boardrooms and training facilities. However, with the rise of home theater systems, the increasing popularity of working from home, and major price reductions and improvements in projector technology, portable projectors are an increasingly popular alternative to large-screen TVs and plasma displays. They can be used with Windows XP Media Center PCs and video players as well as their traditional partners, conventional laptop and desktop computers running any operating system.

Two technologies are used in the construction of data projectors:

- Liquid crystal display (LCD)
- Digital light processing (DLP)

Instead of using triads of subpixels as in a flat-panel or portable LCD, an LCD projector works by separating white light into red, green, and blue wavelengths and directing each wavelength through a corresponding LCD panel. Each LCD panel's pixels are opened or closed according to the signals received from the signal source (computer, DVD, or video player) and are combined into a single RGB image that is projected onto

the screen. A relatively hot projection lamp must be used to project LCD images, so LCD projectors require some cool-down time before they can be stored.

The other major technology for presentation and home theater projectors uses Texas Instruments' own digital light processing (DLP) technology. DLP projectors use a combination of a rapidly spinning color wheel and a microprocessor-controlled array of tiny mirrors known as a *digital micromirror device (DMD)*. Each mirror in a DMD corresponds to a pixel, and the mirrors reflect light toward or away from the projector optics. Depending on how frequently the mirrors are switched on, the image varies from white (always on) to black (never on) through as many as 1,024 gray shades. The color wheel provides color data to complete the projected image. Compared to LCD projectors, DLP projectors are more compact, are lighter, and cool down more quickly after use. Although DLP projects were originally more expensive than LCD projectors, they are now about the same price. You can purchase a variety of LCD and DLP projectors providing 800x600 SVGA images for around \$750, and LCD and DLP 1024x768 XGA projectors are available for about \$1,000.

[Figure 13.6](#) illustrates how a DLP-based processor produces the image.

Figure 13.6. How a typical DLP projector works.

The earliest DLP projectors used a simple three-color (RGB) wheel, as shown in [Figure 13.6](#). However, more recent models have used a four-segment (RGB and clear) or a six-segment (RGBRGB) wheel to improve picture quality.

Note

For more information about digital light processing, see the official Texas Instruments website

about DLP technology at <http://www.dlp.com>.

Plasma Displays

Plasma, the latest technology for large wide-screen displays, actually has a long history. In the late 1980s, IBM developed a monochrome plasma screen that displayed orange text and graphics on a black background. Toshiba used this display in its T3100 and T3200 laptop computers, which featured double-scan CGA/AT&T 6300-compatible 640x400 graphics.

Unlike the early IBM monochrome plasma screen, today's plasma displays are RGB devices capable of displaying 24-bit or 32-bit color, TV, or DVD signals. Plasma screens produce an image by using electrically charged gas (plasma) to illuminate triads of red, green, and blue phosphors, as shown in [Figure 13.7](#).

Figure 13.7. A cross-section of a typical plasma display.

The display and address electrodes create a grid that enables each subpixel to be individually addressed. By adjusting the differences in charge between the display and address electrodes for each triad's subpixels, the signal source controls the picture.

Typical plasma screens range in size from 42" to 50" or larger. Because they are primarily designed for use with DVD, TV, or HDTV video sources, they are optimized for video rather than computer use. Typical resolutions include 852x480 or 1366x768 (Wide XGA). Note that some plasma screens can also support 1024x768 or 1280x1024 (4:3 ratio) VGA video. Given the limited resolution of plasma screens, they are best suited for entertainment rather than computer use, although some do include DVI-HDCP (DVI-D) and VGA ports for use with computer-based video.

Monitor Selection Criteria

Stores offer a dizzying variety of monitor choices, from the low-cost units bundled with computers to large-screen tubes that cost more than many systems. Because a monitor can account for a large part of the price of your computer system, you need to know what to look for when you shop for a monitor.

Important factors to consider include

- Viewable image size
- Resolution
- Dot pitch (CRTs)
- Image brightness and contrast (LCDs)
- Power management and safety certifications
- Vertical and horizontal frequencies
- Picture controls
- Environmental issues (lighting, size, weight)

This section helps you understand these issues so you can make a wise choice for your next display, regardless of the display technology you prefer.

The Right Size

CRT-based monitors come in various sizes ranging from 15" to 42" diagonal measurement. The larger the monitor, the higher the price tag after you get beyond 19" displays, the prices skyrocket. The most common CRT monitor sizes are 17", 19", and 21". These diagonal measurements, unfortunately, often represent not the size of the actual image the screen displays, but the size of the tube.

Although some vendors manufacture LCD panels as small as 14", most vendors are now concentrating on LCD panels with sizes from 17" and larger. If you are comparing CRT and LCD displays, keep in mind that the size of an LCD panel is the same as its active screen area, whereas a CRT's viewable area is typically at least 1" smaller. The *active screen area* refers to the diagonal measurement of the lighted area on the screen. In other words, if you are running Windows, the viewing area is the actual diagonal measure of the desktop. Refer to [Table 13.1](#) to see how typical CRT monitors' viewing areas compare to LCD panels' actual sizes. As a result, LCD displays give you more active screen area for a given screen size than CRTs. Most recent CRT models have an active screen area that is 1" smaller than the CRT's diagonal measurement, but some models might differ slightly. Check the specifications for a particular monitor to determine its actual active screen area. The active screen area is also known as the *viewable image size (VIS)*.

You can adjust many better-quality CRT monitors to display a high-quality image that completely fills the tube from edge to edge. Less-expensive monitors can fill the screen also, but some of them do so only by pushing the monitor beyond its comfortable limits. The result is a distorted image that is worse than the monitor's smaller, properly adjusted picture.

In most cases today, the 17" CRT monitor is the best bargain in the industry. A 17" monitor is recommended for new systems, especially when running Windows, and is not much more expensive than a 15" display. I recommend a 17" CRT monitor as the minimum you should consider for most normal applications. Displays of 19" 21" or larger are recommended for high-end systems, especially in situations where graphics applications are the major focus.

Note

One of the many reasons I don't recommend low-cost computers sold by major retail stores is because they often are bundled with low-quality CRT or LCD monitors. Although most systems with bundled CRT monitors now feature 17" CRTs, most bundled monitors have lower refresh rates, are bulkier, or have other deficiencies compared to high-quality third-party monitors. If you buy the computer and monitor separately, you have a wider choice of displays and can get one of higher quality. You can also opt for an LCD if space, rather than cost, is a major factor. Note that some vendors who make or sell both computers and LCDs, such as Sony and HP, now bundle some of their computer models with LCDs.

Larger monitors are particularly handy for applications such as CAD and desktop publishing, in which the smallest details must be clearly visible. With a 17" or larger display, you can see nearly an entire 8 1/2"x11" print page in 100% view; in other words, what you see onscreen virtually matches the page that will be printed. Being able to see the entire page at its actual size can save you the trouble of printing several drafts of a document or project to get it right.

With the popularity of the Internet, monitor size and resolution become even more of an issue. Many web pages are designed for 800x600 or higher resolutions. Whereas a 15" monitor can handle 800x600 fairly well, a 17" monitor set to 1024x768 resolution enables you to comfortably view any website without eyestrain (if the monitor supports 75Hz or higher refresh rates) or excessive scrolling.

Note

Although many monitors smaller than 17" are physically capable of running at 1024x768 and even higher resolutions, most people have trouble reading print at that size. A partial solution is to enable large icons in the Windows Display properties (right-click your desktop and select Properties). In Windows 98/Me/2000/XP, select Effects, Use Large Icons. Windows 95 doesn't have an option to enlarge only the icons; you can use the Settings tab to select Large Fonts, but some programs will not work properly with font sizes larger than the default Small Fonts setting.

Resolution

Resolution is the amount of detail a monitor can render. This quantity is expressed in the number of horizontal and vertical picture elements, or *pixels*, contained in the screen. The greater the number of pixels, the more detailed the images. The resolution required depends on the application. Character-based applications (such as DOS command-line programs) require little resolution, whereas graphics-intensive applications (such as desktop publishing and Windows software) require a great deal.

It's important to realize that CRTs are designed to handle a range of resolutions natively, but LCD panels (both desktop and notebook) are built to run a single native resolution and must scale to other choices. Older LCD panels handled scaling poorly, but even though current LCD panels perform scaling better, the best results with various resolutions are still found with CRTs.

As PC video technology developed, the screen resolutions video adapters support grew at a steady pace. [Table 13.3](#) shows standard resolutions used in PC graphics adapters and displays and the terms commonly

used to describe them.

Table 13.3. Graphics Display Resolution Standards

Display Standard	Linear Pixels (HxV)	Total Pixels	Aspect Ratio
CGA	320x200	64,000	1.60
EGA	640x350	224,000	1.83
VGA	640x480	307,200	1.33
WVGA	854x480	409,920	1.78
SVGA	800x600	480,000	1.33
XGA	1024x768	786,432	1.33
XGA+	1152x864	995,328	1.33
WXGA	1280x800	1,024,000	1.60
WXGA+	1440x900	1,296,000	1.60
SXGA	1280x1024s	1,310,720	1.25
SXGA+	1400x1050	1,470,000	1.33
WSXGA	1600x1024	1,638,400	1.56
WSXGA+	1680x1050	1,764,000	1.60
UXGA	1600x1200	1,920,000	1.33
HDTV	1920x1080	2,073,600	1.78
WUXGA	1920x1200	2,304,000	1.60
QXGA	2048x1536	3,145,728	1.33
QSXGA	2560x2048	5,242,880	1.25
QUXGA-W	3840x2400	9,216,000	1.60

Aspect ratios:

1.25 = 5:4

1.33 = 4:3

1.56 = 25:16

1.60 = 16:10

1.78 = 16:9

1.83 = 11:6

W = Wide-screen (aspect ratios wider than 1.33)

The Color Graphics Adapter (CGA) and Enhanced Graphics Adapter (EGA) cards and monitors were the first PC graphics standards in the early to mid-1980s. The Video Graphics Array (VGA) standard was released by IBM in April 1987, and all the subsequent resolutions and modes introduced since then have been based on it in one way or another. VGA mode is still in common use as a reference to the standard 640x480 16-color display that most versions of the Windows operating systems use as their default; Windows XP, however, defaults to SVGA mode, which is 800x600. The 15-pin connector through which you connect the analog display to most video adapters is also often called a *VGA port*. A newer 20-pin connector is used for DFP-compatible LCD panels. A larger 24-pin connector is used on DVI-D displays, whereas DVI-I displays use a 29-pin version of the DVI-D connector (refer to [Figure 13.2](#)).

Nearly all video adapters sold today support SXGA (1280x1024) resolutions at several color depths, and many support UXGA (1600x1200) and higher as well. Typically, in addition to the highest setting your card and display will support, any lower settings are automatically supported as well.

Because all CRT and almost all recent and current LCDs can handle various resolutions, you have a choice. As you'll see later in this chapter, the combinations of resolution and color depth (number of colors onscreen) you can choose might be limited by how much RAM your graphics adapter has onboard or, if you have motherboard chipset-based video, how much system memory is allocated to your video function. If you switch to a larger display and you can't set the color depth you want to use, a new video card with more RAM is a desirable upgrade. Video cards once featured upgradeable memory, but this is no longer an option with current models.

Which resolution do you want for your display? Generally, the higher the resolution, the larger the display you will want. Why? Because Windows icons and text use a constant number of pixels, higher display resolutions make these screen elements a smaller part of the desktop onscreen. By using a larger display (17" or larger), you can use higher resolution settings and still have text and icons that are readable.

To understand this issue, you might want to try various resolutions on your system. As you change from 800x600 to 1024x768 and beyond, you'll notice several changes to the appearance of your screen.

At 800x600 or less, text and onscreen icons are very large. Because the screen elements used for the Windows desktop and software menus are at a fixed pixel width and height, you'll notice that they shrink in size onscreen as you change to the higher resolutions. You'll be able to see more of your document or web page onscreen at the higher resolutions because each object requires less of the screen.

If you are operating at 800x600 resolution, for example, you should find a 15" CRT or 14" LCD monitor to be comfortable. At 1024x768, you probably will find that the display of a 15" CRT monitor is too small; therefore, you will probably prefer to use a larger one, such as a 17" monitor. However, a 15" LCD works very well in 1024x768 resolution. [Table 13.4](#) shows the smallest monitors I recommend to properly display the resolutions users typically select.

Table 13.4. Recommended Resolutions for CRT and LCD Displays

Resolution	Minimum Recommended CRT Monitor	Minimum Recommended LCD Panel
------------	---------------------------------	-------------------------------

800x600	15"	14"
1024x768	17"	15"
1280x1024	19"	17"
1600x1200	21"	18"

If you compare the recommended resolutions in [Table 13.4](#) with those listed in [Table 13.1](#), you'll notice that the recommended resolutions are not necessarily the limits of a given monitor's capabilities. However, I recommend these resolutions to help ensure a comfortable computing experience. On small monitors set to high resolutions, characters, icons, and other information are too small for most users and can cause eyestrain. Low-cost CRT monitors and those bundled with many systems often produce blurry results when set to their maximum resolution and often have low refresh rates at their highest resolution. Low refresh rates cause screen flicker, leading to increased eyestrain.

Whereas CRTs can produce poor-quality results at very high resolutions, LCDs are always crisp and perfectly focused by nature. Also, the dimensions advertised for the LCD screens represent the exact size of the viewable image, unlike most conventional CRT-based monitors. In addition, the LCD is so crisp that screens of a given size can easily handle resolutions that are higher than what would otherwise be acceptable on a CRT.

For example, many of the high-end notebook systems now use 14" or 15" LCD panels that feature SXGA+ (1400x1050) or even UXGA (1600x1200) resolution. Although these resolutions would be unacceptable on a CRT display of the same size, they work well on the LCD panel built in to the laptop because of the crystal-clear image and because you generally sit closer to a laptop display. In fact, it is for this reason that such high resolutions might not work on desktop LCD panels unless they are larger 17" or 18" models.

Dot Pitch (CRTs)

Another important specification that denotes the quality of a given CRT monitor is its dot pitch, which is controlled by the design of the shadow mask or aperture grille inside the CRT. A *shadow mask* is a metal plate built into the front area of the CRT, next to the phosphor layers. It has thousands of holes that are used to help focus the beam from each electron gun so that it illuminates only one correctly colored phosphor dot at a time. Because of the immense speed of screen rewriting (6085 times per second), all dots appear to be illuminated at the same time. The mask prevents the electron gun from illuminating the wrong dots.

In a monochrome monitor, the picture element is a screen phosphor, but in a color monitor, the picture element is a phosphor triad, which is a group of three phosphor dots (red, green, and blue). Dot pitch, which applies only to color monitors, is the distance (in millimeters) between phosphor triads, measured from the center of a phosphor dot in a given triad to the same color phosphor dot in the next triad. Screens with a small dot pitch have a smaller space between the phosphor triads. As a result, the picture elements are closer together, producing a sharper picture onscreen. Conversely, screens with a large dot pitch tend to produce images that are less clear. [Figure 13.8](#) illustrates dot pitch.

Figure 13.8. Dot pitch is the distance between each group (triad) of red, green, and blue (RGB) phosphors. A smaller dot pitch helps produce sharper, clearer images.

Note

Dot pitch is not an issue with LCD portable or desktop display panels because of their designs, which use transistors rather than phosphor triads.

The original IBM PC color monitor had a dot pitch of .43mm, which is considered to be poor by almost any standard. Smaller pitch values indicate sharper images. Most recent monitors have a dot pitch between .25mm and .27mm, with state-of-the-art monitors down to .24mm or less. To avoid grainy images, look for a dot pitch of .26mm or smaller. Be wary of monitors with anything larger than a .28mm dot pitch; they lack clarity for fine text and graphics. Although you can save money by buying monitors with smaller tubes or a higher dot pitch, the trade-off isn't worth it.

Monitors based on Sony's Trinitron picture tubes and Mitsubishi's DiamondTron picture tubes use an aperture grille, which uses vertical stripes (rather than a shadow mask) to separate red, green, and blue phosphors. This produces a brighter picture, although the stabilizing wires shown in [Figure 13.9](#) are visible on close examination. Monitors using an aperture grille-type picture tube use a stripe pitch measurement instead of dot pitch. An aperture grille monitor stripe pitch of .25mm is comparable to a .27mm dot pitch on a conventional monitor.

Some of NEC's monitors use a variation on the aperture grille called the slotted mask, which is brighter than standard shadow-mask monitors and more mechanically stable than aperture grille-based monitors (see [Figure 13.9](#)).

Figure 13.9. Aperture-grille picture tubes (left) have their phosphors arranged in vertical stripes with one or two reinforcing wires, depending on CRT size. NEC's ChromaClear slotted mask picture tube design (right) provides many of the benefits of both the shadow-mask and aperture-grille designs.

The dot pitch or stripe pitch measurement is one of the most important specifications of any monitor, but it is not the only specification. You might find the image on a monitor with a slightly higher dot pitch superior to that of a monitor with a lower dot pitch. There is no substitute for actually looking at images and text on the monitors you're considering purchasing.

Image Brightness and Contrast (LCD Panels)

As previously mentioned, dot pitch is not a factor in deciding which LCD panel to purchase. Although it's a consideration that applies to both LCDs and CRTs, the brightness of a display is especially important in judging the quality of an LCD panel.

Although a dim CRT display is almost certainly a sign of either improper brightness control or a dying monitor, brightness in LCD panels can vary a great deal from one model to another. Brightness for LCD panels is measured in candelas per square meter, which is abbreviated "nt" and pronounced as a *nit*. Typical ratings for good display panels are between 200 and 400 nits, but the brighter the better. A good combination is a rating of 250 nits or higher and a contrast rating of 300:1 or higher.

Note

When you evaluate an LCD TV monitor, be sure to note the brightness settings available in computer mode and TV mode. Many of these displays provide a brighter picture in TV mode than in computer mode.

Interlaced Versus Noninterlaced

Monitors and video adapters can support interlaced or noninterlaced resolution. In *noninterlaced* (conventional) mode, the electron beam sweeps the screen in lines from top to bottom, one line after the

other, completing the screen in one pass. In *interlaced* mode, the electron beam also sweeps the screen from top to bottom, but it does so in two passesweeping the odd lines first and the even lines second. Each pass takes half the time of a full pass in noninterlaced mode. Early high-resolution monitors, such as the IBM 8514/A, used interlacing to reach their maximum resolutions, but all recent and current high-resolution (1,024x768 and higher) monitors are noninterlaced, avoiding the slow screen response and flicker caused by interlacing.

For more information about interlaced displays, see "[Interlaced Versus Noninterlaced](#)" in [Chapter 15](#) of *Upgrading and Repairing PCs, 12th Edition*, included in electronic form on the disc accompanying this book.

Note

If you watch HDTV, you might also be using an interlaced display. HDTV broadcast in 1080i mode is interlaced, but because of technical improvements since the days of the 8514/A display, flicker is eliminated and the picture quality is very high. Some broadcasters prefer to use the noninterlaced 720p HDTV mode, which produces slightly better handling of fast motion. Any HDTV-compatible TV or projector can use either mode, but some must adapt the signal they receive to their native resolution. For more information about HDTV modes, see the article "HDTV in Plain English" at http://www.projectorcentral.com/hdtv_edtv.htm.

Energy and Safety

Monitors, like virtually all power-consuming computer devices, have been designed to save energy for a number of years. Virtually all monitors sold in recent years have earned the Environmental Protection Agency's Energy Star logo by reducing their current draw to 15 watts or less when idle.

Power-management features in the monitor, as well as controls provided in the system BIOS and in the latest versions of Windows, help monitors and other types of computing devices use less power.

For more information about power management, see [Chapter 19](#), "Power Supplies," p. [1143](#).

Power Management

One of the first energy-saving standards for monitors was VESA's Display Power-Management Signaling (DPMS) spec, which defined the signals a computer sends to a monitor to indicate idle times. The computer or video card decides when to send these signals.

In Windows 9x/Me/2000/XP, you must enable this feature if you want to use it because it's turned off by default. To enable it in Windows 9x/Me, open the Display properties in the Control Panel, switch to the Screen Saver tab, and make sure the Energy Star Low-Power settings and Monitor Shutdown settings are checked. You can adjust how long the system remains idle before the monitor picture is blanked or the monitor shuts down completely. Use the Power icon in Windows 2000/XP to set power management for the monitor and other peripherals. You can also access power management by selecting the Screen Saver tab on the Display properties sheet and clicking the Power button.

Intel and Microsoft jointly developed the Advanced Power Management (APM) specification, which defines a

BIOS-based interface between hardware that is capable of power-management functions and an operating system that implements power-management policies. In short, this means you can configure an OS such as Windows 9x to switch your monitor into a low-power mode after an interval of nonuse and even to shut it off entirely. For these actions to occur, however, the monitor, system BIOS, and operating system must all support the APM standard.

With Windows 98, Windows Me, Windows 2000, and Windows XP, Microsoft introduced a more comprehensive power-management method called Advanced Configuration and Power Interface (ACPI). ACPI also works with displays, hard drives, and other devices supported by APM and allows the computer to automatically turn peripherals, such as CD-ROMs, network cards, hard disk drives, and printers, on and off. It also enables the computer to turn consumer devices connected to the PC, such as VCRs, televisions, telephones, and stereos, on and off.

Although APM compatibility has been standard in common BIOSs for several years, a number of computers from major manufacturers required BIOS upgrades to add ACPI support when Windows 98 was introduced.

Note

ACPI support is installed with Windows 98 and newer *only* if an ACPI-compliant BIOS is present when Windows is first installed. If an ACPI-compliant BIOS is installed after the initial Windows installation, it is ignored.

Use [Table 13.5](#) to select the most appropriate DPMS power-management setting(s) for your needs. Most recent systems enable you to select separate values for standby (which saves minimal amounts of power) and for monitor power-down (which saves more power but requires the user to wait several seconds for the monitor to power back up).

Table 13.5. Display Power Management Signaling

State	Horizontal	Vertical	Video	Power Savings	Recovery Time
On	Pulses	Pulses	Active	None	n/a
Stand-By	No Pulses	Pulses	Blanked	Minimal	Short
Suspend	Pulses	No Pulses	Blanked	Substantial	Longer
Off	No Pulses	No Pulses	Blanked	Maximum	System Dependent

Virtually all monitors with power management features meet the requirements of the United States EPA's Energy Star labeling program, which requires that monitor power usage be reduced to 15 watts or less in standby mode. However, some current monitors also comply with the far more stringent Energy 2000 (E2000) standard developed in Switzerland. E2000 requires that monitors use less than 5 watts when in standby mode.

Emissions (CRTs)

Another trend in green CRT monitor design is to minimize the user's exposure to potentially harmful electromagnetic fields. Several medical studies indicate that these electromagnetic emissions can cause health problems, such as miscarriages, birth defects, and cancer. The risk might be low, but if you spend a third of your day (or more) in front of a CRT monitor, that risk is increased.

The concern is that VLF (very low frequency) and ELF (extremely low frequency) emissions might affect the body. These two emissions come in two forms: electric and magnetic. Some research indicates that ELF magnetic emissions are more threatening than VLF emissions because they interact with the natural electric activity of body cells. Monitors are not the only culprits; significant ELF emissions also come from electric blankets and power lines.

Note

ELF and VLF are a form of electromagnetic radiation; they consist of radio frequencies below those used for normal radio broadcasting.

The standards shown in [Table 13.6](#) have been established to regulate emissions and other aspects of monitor operations. Even though these standards originated with Swedish organizations, they are recognized and supported throughout the world.

Table 13.6. Monitor Emissions Standards

Standard Name	Established by	Date Established	Regulates	Notes
MPR I	SWEDAC ^[1]	1987	Monitor emissions	Replaced by MPR II
MPR II	SWEDAC ^[1]	1990	Monitor emissions	Added maximums for ELF and VLF; minimum standard in recent monitors
TCO ^[2]	TCO ^[2]	1992, 1995, 1999, 2003		Tighter monitor emissions limits than MPR-II; power management TCO '95, '99, and '03 add other classes of devices to the TCO standard

^[1] *The Swedish Board for Accreditation and Conformity Assessment*

^[2] *Swedish abbreviation for the Swedish Confederation of Professional Employees*

Today, virtually all monitors on the market support TCO standards.

If you are using an older monitor that does not meet TCO standards, you can take other steps to protect yourself. The most important is to stay at arm's length (about 28 inches) from the front of your monitor. When you move a couple of feet away, ELF magnetic emission levels usually drop to those of a typical office with fluorescent lights. Likewise, monitor emissions are weakest at the front of a monitor, so stay at least 3 feet from the sides and backs of nearby monitors and 5 feet from any photocopiers, which are also strong sources of ELF.

Electromagnetic emissions should not be your only concern; you also should be concerned about screen glare. In fact, some of the antiglare panels that fit in front of a monitor screen not only reduce eyestrain, but also cut ELF and VLF emissions.

Note that because plasma and LCD panels don't use electron guns or magnets, they don't produce ELF emissions.

Frequencies

One essential buying decision is to choose a monitor that works with your selected video adapter. Today, virtually all monitors are multiple-frequency (also called multiscanning and multifrequency) units that accommodate a range of standards, including those that are not yet standardized. However, big differences exist in how well various monitors cope with various video adapters.

Tip

High-quality monitors retain their value longer than most other computer components. Although it's common for a newer, faster processor to come out right after you have purchased your computer or to find the same model with a bigger hard disk for the same money, a good quality monitor should outlast your computer. If you purchase a unit with the expectation that your own personal requirements will grow over the years, you might be able to save money on your next system by reusing your old monitor.

Some useful features include the following:

- Front-mounted digital controls that can memorize screen settings
- Onscreen programmability to enable you to precisely set desired values for screen size and position
- Self-test mode, which displays a picture even when your monitor is not receiving a signal from the computer

With multiple-frequency CRT monitors, you must match the range of horizontal and vertical frequencies the monitor accepts with those generated by your video adapter. The wider the range of signals, the more expensive and more versatile the monitor. Your video adapter's vertical and horizontal frequencies must fall within the ranges your monitor supports. The vertical frequency (or refresh/frame rate) determines the stability of your image (the higher the vertical frequency, the better). Typical vertical frequencies range from 50Hz to 160Hz, but multiple-frequency monitors support different vertical frequencies at different resolutions. You might find that a bargain monitor has a respectable 120Hz vertical frequency at 640x480 but drops to a less desirable 66Hz at 1280x1024. The horizontal frequency (or line rate) typically ranges from 31.5KHz to 90KHz or more. By default, most video adapters use a 60Hz default vertical scan frequency to avoid monitor damage.

Although LCD monitors use lower vertical frequencies than CRTs, they avoid problems with screen flicker because of their design. Because they use transistors to activate all the pixels in the image at once, as opposed to a scanning electron beam that must work its way from the top to the bottom of the screen to create an image, LCD panels never flicker.

Refresh Rates (Vertical Scan Frequency)

The *refresh rate* (also called the vertical scan frequency) is the rate at which the screen display is rewritten. This is measured in hertz. A refresh rate of 72Hz means that the screen is refreshed 72 times per second. A refresh rate that is too low causes CRT screens to flicker, contributing to eyestrain. The higher the refresh rate you use with a CRT display, the better for your eyes and your comfort during long sessions at the computer.

A *flicker-free refresh rate* is a refresh rate high enough to prevent you from seeing any flicker. The flicker-free refresh rate varies with the resolution of your monitor setting (higher resolutions require higher refresh rates) and must be matched by both your monitor and display card. Because a refresh rate that is too high can slow down your video display, use the lowest refresh rate that is comfortable for you.

One important factor to consider when purchasing a CRT monitor is the refresh rate, especially if you are planning to use the monitor at 1024x768 or higher resolutions. Low-cost monitors sometimes have refresh rates that are too low to achieve flicker-free performance for most users and thus can lead to eyestrain.

[Table 13.7](#) compares two typical 19" CRT monitors and two typical mid-range graphics cards using ATI and NVIDIA GPUs.

Table 13.7. Refresh Rates Comparison

Resolution	ATI Radeon X700 (ATI Chipset)	eVGA e-GeForce 6800 GS (NVIDIA Chipset)	ViewSonicE90f 19" CRT	ViewSonic G225fB 19" CRT
1024x768	Up to 200Hz	Up to 200Hz ^[1]	106Hz ^[2]	155Hz ^[2]
1280x1024	Up to 160Hz	Up to 150Hz ^[1]	80Hz ^[3]	118Hz ^[2]
1600x1200	Up to 120Hz	Up to 100Hz ^[1]	68Hz	102Hz ^[1]
1920x1440	Up to 90Hz	Up to 75Hz ^[1]	Not supported	85Hz ^[1]

^[1] Maximum refresh rate for 32-bit color; it's slightly higher for 16-bit or 8-bit color.

^[2] Meets or exceeds the VESA standard for flicker-free refresh (85Hz or above).

[3] *Although this refresh rate is lower than the VESA standard for flicker-free refresh (85Hz), it will be flicker-free for many users.*

Note the differences in the refresh rates supported by the graphics cards and two 19" CRT monitors from ViewSonic: the E90f and G225fB.

The E90f sells for around \$170, and the G225fB sells for about \$450. The G225fB offers flicker-free refresh rates at higher resolutions than the cheaper E90f.

Although the video cards listed in [Table 13.7](#) support higher refresh rates than either monitor, these rates can't be used safely. Use of video adapter refresh rates in excess of the monitor's maximum refresh rate can damage the monitor!

To determine a monitor's refresh rates for the resolutions you're planning to use, check out the monitor manufacturer's website.

Note

Many manufacturers use the term *optimal resolution* to refer to the highest CRT monitor resolution that supports the VESA standard for flicker-free viewing (85Hz or higher). I recommend that you consider the monitor's optimal resolution as its highest practical resolution because higher resolutions, which don't support flicker-free viewing, are likely to provide poor visual quality.

During installation, Windows 2000, Windows 98, Windows 95B (OSR 2.x), Windows Me, and Windows XP support Plug and Play (PnP) monitor configuration if both the monitor and video adapter support the Data Display Channel (DDC) feature. When DDC communication is available, the monitor can send signals to the operating system that indicate which refresh rates it supports, as well as other display information; this data is reflected by the Display Properties sheet for that monitor.

Monitors that don't support PnP configuration via DDC can be configured with an .INF (information) file, just as with other Windows-compatible devices. This might be supplied with a setup disk or CD or can be downloaded from the monitor vendor's website.

Note

Because CRT monitors are redrawing the screen many times per second, the change in a noninterlaced CRT screen display is virtually invisible to the naked eye, but it is very obvious when computer screens are photographed, filmed, or videotaped. Because these cameras aren't synchronized to the monitor's refresh cycle, it's inevitable that the photo, film, or videotape will show the refresh in progress as a line across the picture.

If you need to capture moving images from a monitor to videotape, use a video card with a TV-out option to send your picture to a VCR. If you need to take still photos of a monitor (for example, to record BIOS/CMOS setup information), use an LCD display instead of a CRT monitor.

In my experience, a 72Hz vertical scan frequency (frame rate) is the minimum anybody should use with a CRT, especially at resolutions of 1024x768 and higher. Lower resolutions produce a noticeable flicker, which can cause eyestrain, fatigue, and headaches. 72Hz is the minimum refresh rate I recommend because most people do not notice flicker at this refresh rate or higher. Most modern mid-range or better CRT displays easily handle vertical frequencies up to 85Hz or more at resolutions up to 1024x768. This greatly reduces the flicker a user sees. However, note that, although increasing the frame rate improves the quality of the image, it can also slow down the video hardware because it now needs to display each image more times per second. If you're a gamer, slower frame rates can reduce your score. In general, I recommend that you set the lowest frame rate you find comfortable. To adjust the video card's refresh rate with Windows 9x/Me/2000/XP, use the Display icon in Control Panel. Click Settings and then Advanced to access the tabs for refresh rate.

Depending on your flavor of Windows, the refresh rates supported by the video card will appear on one of the advanced Display tabs. With Windows XP, for example, you use the Monitor tab to select the desired screen refresh rate.

Tip

If you use multiple monitors, be sure to select the monitor you want to adjust in the Settings dialog box before opening the Advanced dialog box to select a refresh rate.

You can also use the Adapter tab to select the resolution, color quality, and refresh rate with a single click.

Optimal is the default setting, but this really is a "safe" setting for any monitor. Select a refresh rate of at least 72Hz or higher to reduce or eliminate flicker. Click Apply for the new setting to take effect. If you choose a refresh rate other than Optimal, you might see a warning about possible monitor damage. This is a warning you should take seriously, especially if you don't have detailed information about your monitor available. You can literally smoke a monitor if you try to use a refresh rate higher than the monitor is designed to accept. Before you try using a custom refresh rate, do the following:

- Make sure Windows has correctly identified your monitor as either a Plug and Play monitor or by brand and model.
- Check the manual supplied with the monitor (or download the statistics) to determine which refresh rates are supported at a given resolution. As in the example listed earlier in [Table 13.7](#), low-cost monitors often don't support high refresh rates at higher resolutions.

Click OK to try the new setting. The screen changes to show the new refresh rate. If the screen display looks scrambled, wait a few moments and the screen will be restored to the previous value; you'll see a dialog box asking whether you want to keep the new setting. If the display was acceptable, click Yes; otherwise, click No to restore your display. If the screen is scrambled and you can't see your mouse pointer, just press the Enter key on your keyboard because No is the default answer. With some older video drivers, this refresh rate dialog box is not available. Get an updated video driver, or check with the video card vendor for a separate utility program that sets the refresh rate for you.

If you have a scrambled display with a high refresh rate, but you think the monitor should be capable of handling the refresh rate you chose, you might not have the correct monitor selected. To check your Windows 9x/Me/2000/XP monitor selection, check the Display Properties dialog box. If your monitor is

listed as Standard VGA, Super VGA, or Default Monitor, Windows is using a generic driver that will work with a wide variety of monitors. However, this generic driver doesn't support refresh rates above 75Hz because some monitors could be damaged by excessively high refresh rates.

In some cases, you might need to manually select the correct monitor brand and model in the Windows Display Properties dialog box. If you don't find your brand and model of monitor listed, check with your monitor vendor for a driver specific for your model. After you install it, see whether your monitor will safely support a higher refresh rate.

Tip

If you try to use a refresh rate higher than an LCD panel can support, you might see a message that you have selected an out-of-range frequency. Typically, LCD panels do not accept a vertical refresh rate higher than 75Hz. Keep in mind that LCDs do not flicker, so it's acceptable to use refresh rates as low as 60Hz with an LCD display. If you use a dual-head video card, keep in mind that some models don't permit you to assign different refresh rates to each monitor. If you have a CRT and an LCD connected to such a video card, use the highest refresh rate supported by both displays (usually 75Hz) to minimize flicker on the CRT.

Horizontal Frequency

Different video resolutions use different horizontal frequencies. For example, the standard VGA resolution of 640x480 requires a horizontal resolution of 31.5KHz, whereas the 800x600 resolution requires a vertical frequency of at least 72Hz and a horizontal frequency of at least 48KHz. The 1024x768 image requires a vertical frequency of 60Hz and a horizontal frequency of 58KHz, and the 1280x1024 resolution requires a vertical frequency of 60Hz and a horizontal frequency of 64KHz. If the vertical frequency increases to 75Hz at 1280x1024, the horizontal frequency must be 80KHz. For a super-crisp display, look for available vertical frequencies of 75Hz or higher and horizontal frequencies of up to 90KHz or more. My favorite 17" NEC monitor supports vertical resolutions of up to 75Hz at 1600x1200 pixels, 117Hz at 1024x768, and 160Hz at 640x480!

Virtually all the analog monitors on the market today are, to one extent or another, multiple-frequency. Because literally hundreds of manufacturers have produced thousands of monitor models, it is impractical to discuss the technical aspects of each monitor model in detail. Suffice it to say that before investing in a monitor, you should check the technical specifications to ensure that the monitor meets your needs. If you are looking for a place to start, check out some of the magazines that periodically feature reviews of monitors. If you can't wait for a magazine review, investigate monitors at the websites run by any of the following vendors: IBM, Sony, NEC-Mitsubishi, and ViewSonic. Each of these manufacturers creates monitors that set the standards by which other monitors can be judged. Although you typically pay a bit more for these manufacturers' monitors, they offer a known, high level of quality and compatibility, as well as service and support. Note that most monitor companies sell several lines of monitors, varying by refresh rates, CRT type, antiglare coatings, energy efficiency, and warranties. For best results at resolutions of 1024x768 and above, avoid the lowest-cost 17" CRT monitors because these models tend to produce fuzzy onscreen displays with low refresh rates.

Controls

Most of the newer CRT monitors and LCD panels use digital controls instead of analog controls. This has nothing to do with the signals the monitor receives from the computer, but only the controls (or lack of

them) on the front panel that enable you to adjust the display. Monitors with digital controls have a built-in menu system that enables you to set parameters such as brightness (which adjusts the black level of the display), contrast (which adjusts the luminance of the display), screen size, vertical and horizontal shifts, color, phase, and focus. A button brings the menu up onscreen, and you use controls to make menu selections and vary the settings. When you complete your adjustments, the monitor saves the settings in nonvolatile RAM (NVRAM) located inside the monitor. This type of memory provides permanent storage for the settings with no battery or other power source. You can unplug the monitor without losing your settings, and you can alter them at any time in the future. Digital controls provide a much higher level of control over the monitor and are highly recommended.

Tip

Digital video engineer Charles Poynton's notes on adjusting brightness and contrast controls provide an excellent tutorial on the use of these often misunderstood monitor adjustments. Find them online at <http://www.vision.ee.ethz.ch/~buc/brechbuehler/mirror/color/Poynton-color.html>.

Digital controls make adjusting CRT monitors suffering from any of the geometry errors shown in [Figure 13.10](#) easy. Before making these adjustments, be sure the vertical and horizontal size and position are correct.

Figure 13.10. Typical geometry errors in CRT monitors; these can be corrected on most models that have digital picture controls.

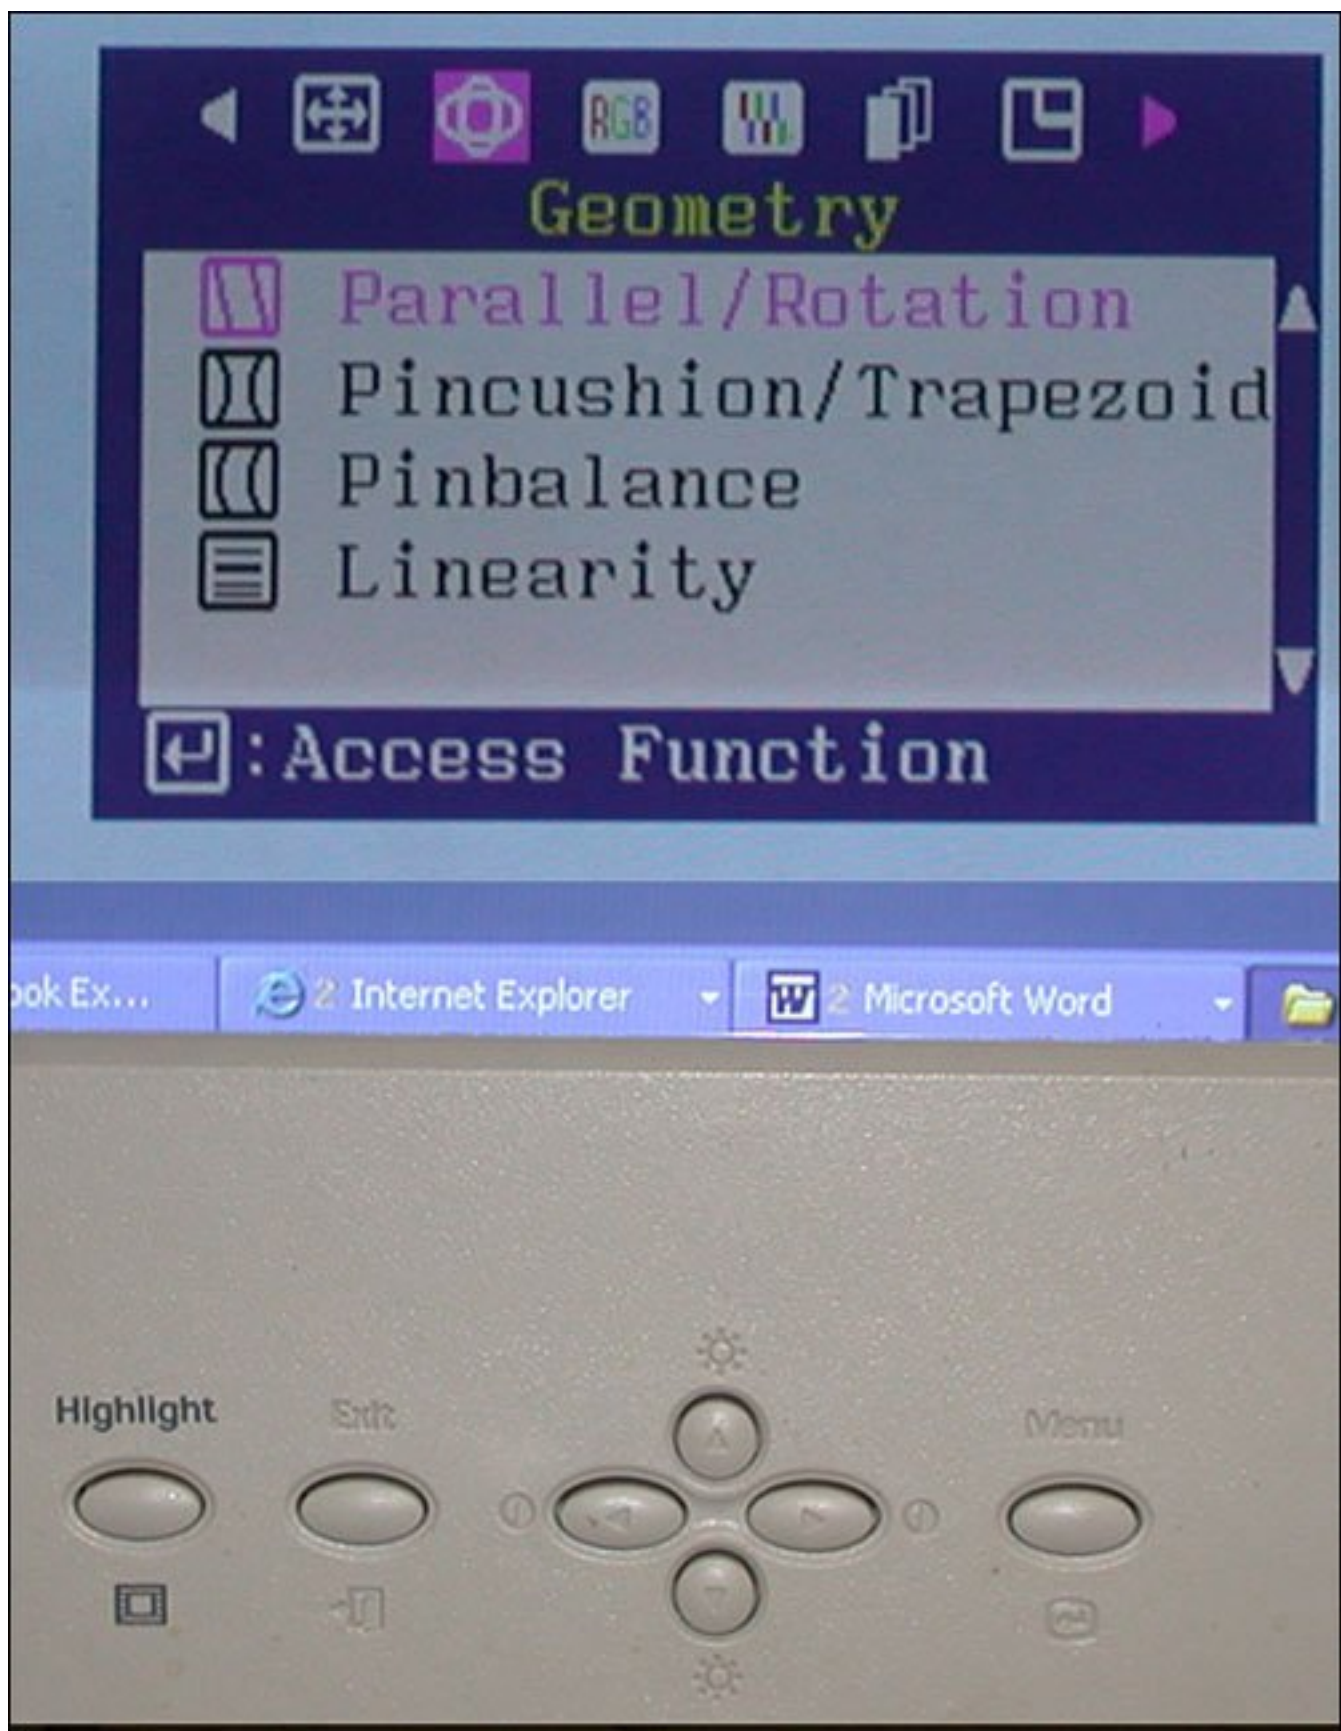

Tip

Get a monitor with positioning and image controls that are easy to reach, preferably on the front of the case. Look for more than just basic contrast and brightness controls; a good monitor should enable you to adjust the width and height of your screen images and the placement of the image on the screen. The monitor should also be equipped with a tilt-swivel stand so you can adjust the monitor to the best angle for your use.

[Figure 13.11](#) shows a typical onscreen display used to correct the screen geometry errors shown in [Figure 13.10](#). The OSD shown is from a Samsung SyncMaster 955DF, but other brands use somewhat similar displays. Buttons below the screen are used to make and store the adjustments.

Figure 13.11. Using an OSD to correct CRT screen geometry errors.

[\[View full size image\]](#)

Although LCD panels aren't affected by geometry errors as CRT monitors can be, they can have their own set of image-quality problems, especially if they use the typical 15-pin analog VGA video connector. Pixel jitter and pixel swim (in which adjacent pixels turn on and off) are relatively common problems that occur when using an LCD monitor connected to your PC with an analog VGA connector.

The Auto-Tune option available in many LCD panels' OSDs can be used to fix these and other LCD display problems, as shown in [Figure 13.12](#). The OSD shown in [Figure 13.12](#) is from a KDS Rad-5, but other brands offer similar options.

Figure 13.12. Using an OSD to correct LCD image quality problems.

Testing a Display

Unlike most of the other peripherals you can connect to your computer, you can't really tell whether a monitor suits you by examining its technical specifications. Price might not be a reliable indicator either. Testing monitors is a highly subjective process, and it is best to "kick the tires" of a few at a dealer showroom or in the privacy of your home or office (if the dealer has a liberal return policy).

Testing should also not be simply a matter of looking at whatever happens to be displayed on the monitor at the time. Many computer stores display movies, scenic photos, or other flashy graphics that are all but useless for a serious evaluation and comparison. If possible, you should look at the same images on each monitor you try and compare the manner in which they perform a specific series of tasks.

Before running the tests listed here, set your display to the highest resolution and refresh rate allowed by your combination of display and graphics card.

One good series of tasks is as follows:

- *Draw a perfect circle with a graphics program.* If the displayed result is an oval, not a circle, this monitor will not serve you well with graphics or design software.
- *Using a word processor, type some words in 8- or 10-point type (1 point equals 1/72").* If the words are fuzzy or the black characters are fringed with color, select another monitor.
- *Display a screen with as much white space as possible and look for areas of color variance.* This can indicate a problem with only that individual unit or its location, but if you see it on more than one monitor of the same make, it might indicate a manufacturing problem; it could also indicate problems with the signal coming from the graphics card. Move the monitor to another system equipped with a different graphics card model and retry this test to see for certain whether it's the monitor or the video card.
- *Display the Microsoft Windows desktop to check for uniform focus and brightness.* Are the corner icons as sharp as the rest of the screen? Are the lines in the title bar curved or wavy? Monitors usually are sharply focused at the center, but seriously blurred corners indicate a poor design. Bowed lines can be the result of a poor video adapter or incorrect configuration of the monitor's digital picture controls. Before you decide to replace the monitor, you should first adjust the digital picture controls to improve the display. Next, try attaching the monitor to another display adapter. If the display quality does not improve, replace the monitor.

Adjust the brightness up and down to see whether the image blooms or swells, which indicates the monitor is likely to lose focus at high brightness levels. You can also use diagnostics that come with the graphics card or third-party system diagnostics programs to perform these tests.

- *With LCD panels in particular, change to a lower resolution from the panel's native resolution using the Microsoft Windows Display properties settings.* Because LCD panels have only one native resolution, the display must use scaling to handle other resolutions full-screen. If you are a web designer, are a gamer, or must capture screens at a particular resolution, this test will show you whether the LCD panel produces acceptable display quality at resolutions other than normal. You can also use this test on a CRT, but CRTs, unlike LCD panels, are designed to handle a wide variety of resolutions.
- *A good CRT monitor is calibrated so that rays of red, green, and blue light hit their targets (individual phosphor dots) precisely.* If they don't, you have bad convergence. This is apparent when edges of lines appear to illuminate with a specific color. If you have good convergence, the colors are crisp, clear, and true, provided there isn't a predominant tint in the phosphor.
- *If the monitor has built-in diagnostics (a recommended feature), try them as well to test the display independently of the graphics card and system to which it's attached.* A display with built-in diagnostics displays text or a test pattern onscreen if it is receiving power when the host system is turned off or if the monitor is not connected to a host system.

Maintaining Your Monitor

Because a good 17" or larger CRT or 15" or larger LCD monitor can be used for several years on more than one computer, proper care is essential to extend its life to the fullest extent.

Use the following guidelines for proper care of your monitor:

- *Although phosphor burn (in which an image left onscreen eventually leaves a permanent shadow onscreen) is next to impossible with VGA-type displaysunlike the old TTL displayscreensavers are still useful for casual security.* You can password-protect your system with both the standard Windows screensaver and third-party programs (although a determined snoop can easily thwart screensaver password protection). Windows includes several screensavers that can be enabled via the Display Control Panel. A bevy of free and inexpensive screensavers is available for download from the Internet. Keep in mind, though, that add-on screensavers can cause crashes and lockups if they're poorly written or out of date and that many "free" versions available online might install spyware (software that reports your web-surfing habits to advertisers). Use screensavers written for your particular operating system version to minimize problems.

Note

Phosphor burn *is* possible with plasma displays, so if you decide to connect a plasma display to your PC, be sure to use a screensaver to protect your display.

- *To prevent premature failure of the monitor's power supply, use the power-management feature of the Display Properties or Power (Management) sheet to put the monitor into a low-power standby mode after a reasonable period of inactivity (1015 minutes) and to turn it off after about 60 minutes.* Using the power management feature is far better than using the on/off switch when you are away from the computer for brief periods. Turn off the monitor only at the end of your computing "day."

How can you tell whether the monitor is really off or in standby mode? Look at the power LCD on the front of the monitor. A monitor that's in standby mode usually has a blinking green or solid amber LCD in place of the solid green LCD displayed when it's running in normal mode. Because monitors in standby mode still consume some power, they should be shut off at the end of the computing day.

If the monitor will not go into standby when the PC isn't sending signals to it, make sure the monitor is properly defined in Windows's Display Properties sheet. In addition, the Energy Star check box should be selected for any monitor that supports power management, unless the monitor should be left on at all times (such as when used in a retail kiosk or self-standing display).

- *Make sure the monitor has adequate ventilation along the sides, rear, and top.* Because monitors use passive cooling, a lack of adequate airflow caused by piling keyboards, folders, books, or other office debris on top of the monitor will cause it to overheat and considerably shorten its life. If you're looking at a monitor with a partly melted grille on the top of the case, you're looking at a victim of poor cooling. If you need to use a monitor in an area with poor airflow, use an LCD panel instead of a CRT because LCDs run much cooler than CRTs.
- *The monitor screen and case should be kept clean.* Turn off the power, spray a cleaner such as

Endust for Electronics onto a soft cloth (never directly onto the monitor!), and wipe the screen and the case gently.

- *If your CRT monitor has a degaussing button or feature, use it periodically to remove stray magnetic signals.* Keep in mind that CRTs have powerful magnets around the picture tube, so keep magnetic media away from them.

Video Display Adapters

A video adapter provides the interface between your computer and your monitor and transmits the signals that appear as images on the display. Throughout the history of the PC, there have been a succession of standards for video display characteristics that represent a steady increase in screen resolution and color depth. The following list of standards can serve as an abbreviated history of PC video-display technology:

MDA (Monochrome Display Adapter)	VGA (Video Graphics Array)
HGC (Hercules Graphics Card)	SVGA (Super VGA)
CGA (Color Graphics Adapter)	XGA (Extended Graphics Array)
EGA (Enhanced Graphics Adapter)	UGA (Ultra Video Graphics Array)

IBM pioneered most of these standards, but other manufacturers of compatible PCs adopted them as well. Today, IBM no longer sets standards for the PC business (it even sold its PC business to China's Lenovo in 2005), and many of these standards are obsolete. Those that aren't obsolete seldom are referred to by these names anymore. The sole exception to this is *VGA*, which is a term that is still used to refer to a baseline graphics display capability supported by virtually every video adapter on the market today.

When you shop for a video adapter today, you are more likely to see specific references to the screen resolutions and color depths that the device supports than a list of standards such as VGA, SVGA, XGA, and UVGA. However, reading about these standards gives you a good idea of how video-display technology developed over the years and prepares you for any close encounters you might have with legacy equipment from the dark ages.

Today's VGA and later video adapters can also display most older color graphics software written for CGA, EGA, and most other obsolete graphics standards. This enables you to use older graphics software (such as games and educational programs) on your current system. Although not a concern for most users, some older programs wrote directly to hardware registers that are no longer found on current video cards.

Obsolete Display Adapters

Although many types of display systems were at one time considered to be industry standards, few of these are viable standards for today's hardware and software.

Note

If you are interested in reading more about MDA, HGC, CGA, EGA, or MCGA display adapters, see [Chapter 8](#) of *Upgrading and Repairing PCs, 10th Anniversary Edition*, included on the disc with this book.

The Video Graphics Array Standard

When IBM introduced the PS/2 systems on April 2, 1987, it also introduced the VGA display. On that day, in fact, IBM also introduced the lower-resolution MCGA and higher-resolution 8514 adapters. The MCGA and 8514 adapters did not become popular standards like the VGA did, and both were discontinued.

All current display adapters that connect to the 15-pin VGA analog connector or the DVI analog/digital connector are based on the VGA standard. The VGA connector is shown in [Figure 13.13](#); the pinouts are shown in [Table 13.8](#).

Figure 13.13. VGA connector used for VGA, SVGA, and other VGA-based standards.

Table 13.8. Standard 15-Pin VGA Connector Pinout

Pin #	Function	Direction
1	Red video	Out
2	Green video	Out
3	Blue video	Out
4	Monitor ID 2	In
5	TTL Ground (monitor self-test)	
6	Red analog ground	
7	Green analog ground	
8	Blue analog ground	
9	Key (plugged hole)	
10	Synch Ground	
11	Monitor ID 0	In

12	Monitor ID 1	In
13	Horizontal Synch	Out
14	Vertical Synch	Out
15	Monitor ID 3	In

On the VGA cable connector that plugs in to your video adapter, pin 9 is often pinless. Pin 5 is used only for testing purposes, and pin 15 is rarely used these are often pinless as well. To identify the type of monitor connected to the system, some manufacturers use the presence or absence of the monitor ID pins in various combinations.

Digital Versus Analog Signals

Unlike earlier video standards, which are digital, VGA is an analog system. Why have displays gone from digital to analog when most other electronic systems have gone digital? Compact disc players (digital) have replaced most turntables (analog), mini DV camcorders are replacing 8MM and VHS-based analog camcorders, and TiVo and UltimateTV digital video recorders are performing time-shifting in place of analog VCRs for many users. With a digital television set, you can watch several channels on a single screen by splitting the screen or placing a picture within another picture.

Most personal computer displays introduced before the PS/2 are digital. This type of display generates different colors by firing the RGB electron beams in on-or-off mode, which allows for the display of up to eight colors (23). In the IBM displays and adapters, another signal doubles the number of color combinations from 8 to 16 by displaying each color at one of two intensity levels. This digital display is easy to manufacture and offers simplicity with consistent color combinations from system to system. The real drawback of the older digital displays such as CGA and EGA is the limited number of possible colors.

In the PS/2 systems, IBM went to an analog display circuit. Analog displays work like the digital displays that use RGB electron beams to construct various colors, but each color in the analog display system can be displayed at varying levels of intensity 64 levels, in the case of the VGA. This versatility provides 262,144 possible colors (643), of which 256 could be simultaneously displayed. For realistic computer graphics, color depth is often more important than high resolution because the human eye perceives a picture that has more colors as being more realistic. IBM moved to analog graphics to enhance the color capabilities of its systems.

VGA Features

PS/2 systems incorporated the primary display adapter circuitry onto the motherboard, and both IBM and third-party companies introduced separate VGA cards to enable other types of systems to enjoy the advantages of VGA.

Although the IBM MicroChannel (MCA) computers, such as the PS/2 Model 50 and above, introduced VGA, it's impossible today to find a brand-new replacement for VGA that fits into the obsolete MCA-bus systems. However, a few surplus and used third-party cards might be available if you look hard enough.

The VGA BIOS is the control software residing in the system ROM for controlling VGA circuits. With the BIOS, software can initiate commands and functions without having to manipulate the VGA directly. Programs become somewhat hardware independent and can call a consistent set of commands and

functions built into the system's ROM-control software.

◀◀ See "[Video Adapter BIOS](#)," p. [538](#).

Other implementations of the VGA differ in their hardware but respond to the same BIOS calls and functions. New features are added as a superset of the existing functions, and VGA remains compatible with the graphics and text BIOS functions built into the PC systems from the beginning. The VGA can run almost any software that originally was written for the CGA or EGA, unless it was written to directly access the hardware registers of these cards.

A standard VGA card displays up to 256 colors onscreen, from a palette of 262,144 (256KB) colors; when used in the 640x480 graphics or 720x400 text mode, 16 colors at a time can be displayed. Because the VGA outputs an analog signal, you must have a monitor that accepts an analog input.

VGA displays originally came not only in color, but also in monochrome VGA models, which use color summing. With color summing, 64 gray shades are displayed instead of colors. The summing routine is initiated if the BIOS detects a monochrome display when the system boots. This routine uses an algorithm that takes the desired color and rewrites the formula to involve all three color guns, producing varying intensities of gray. Users who preferred a monochrome display, therefore, could execute color-based applications.

Note

For a listing of the VGA display modes supported by the original IBM VGA card (and thus all subsequent VGA-type cards), see "VGA Display Modes" in [Chapter 15](#) of *Upgrading and Repairing PCs, 12th Edition*, available in electronic form on the disc supplied with this book.

Even the least-expensive video adapters on the market today can work with modes well beyond the VGA standard. VGA, at its 16-color, 640x480 graphics resolution, has come to be the baseline for PC graphical display configurations. VGA is accepted as the least common denominator for all Windows systems and must be supported by the video adapters in all systems running Windows. The installation programs of all Windows versions use these VGA settings as their default video configuration. In addition to VGA, virtually all adapters support a range of higher screen resolutions and color depths, depending on the capabilities of the hardware. If a Windows 9x/Me or Windows XP/2000 system must be started in Safe Mode because of a startup problem, the system defaults to VGA in the 640x480, 16-color mode. Windows 2000 and Windows XP also offer a VGA Mode startup that also uses this mode (Windows XP uses 800x600 resolution) but doesn't slow down the rest of the computer the way Safe Mode (which replaces 32-bit drivers with BIOS services) does.

IBM introduced higher-resolution versions of VGA called XGA and XGA-2 in the early 1990s, but most of the development of VGA standards has come from the third-party video card industry and its trade group, the Video Electronic Standards Association (VESA).

Note

If you are interested in reading more about the XGA and XGA-2 display adapters, see "XGA

and XGA-2" in [Chapter 8](#) of *Upgrading and Repairing PCs, 10th Anniversary Edition*, included on the disc with this book.

Super VGA

When IBM's XGA and 8514/A video cards were introduced, competing manufacturers chose not to attempt to clone these incremental improvements on their VGA products. Instead, they began producing lower-cost adapters that offered even higher resolutions. These video cards fall into a category loosely known as Super VGA (SVGA).

SVGA provides capabilities that surpass those offered by the VGA adapter. Unlike the display adapters discussed so far, SVGA refers not to an adapter that meets a particular specification, but to a group of adapters that have different capabilities.

For example, one card might offer several resolutions (such as 800x600 and 1024x768) that are greater than those achieved with a regular VGA, whereas another card might offer the same or even greater resolutions but also provide more color choices at each resolution. These cards have different capabilities; nonetheless, both are classified as SVGA.

The SVGA cards look much like their VGA counterparts. They have the same connectors, but because the technical specifications from different SVGA vendors vary tremendously, it is impossible to provide a definitive technical overview in this book.

VESA SVGA Standards

The Video Electronics Standards Association includes members from various companies associated with PC and computer video products. In October 1989, VESA recognized that programming applications to support the many SVGA cards on the market was virtually impossible and proposed a standard for a uniform programmer's interface for SVGA cards; it is known as the VESA BIOS extension (VBE). VBE support might be provided through a memory-resident driver (used by older cards) or through additional code added to the VGA BIOS chip itself (the more common solution). The benefit of the VESA BIOS extension is that a programmer needs to worry about only one routine or driver to support SVGA. Various cards from various manufacturers are accessible through the common VESA interface. Today, VBE support is a concern primarily for real-mode DOS applications, usually older games, and for non-Microsoft operating systems that need to access higher resolutions and color depths. VBE supports resolutions up to 1280x1024 and color depths up to 24-bit (16.8 million colors), depending on the mode selected and the memory on the video card. VESA compliance is of virtually no consequence to Windows versions 95 and up. These operating systems use custom video drivers for their graphics cards.

Note

For a listing of VESA BIOS modes by resolution, color depth, and scan frequency, see "[VESA SVGA Standards](#)" in the Technical Reference portion of the disc accompanying this book.

Video Adapter Types

A monitor requires a source of input. The signals that run to your monitor come from a video adapter inside or plugged in to your computer.

The three ways computer systems connect to either CRT or LCD panels are as follows:

- *Add-on video cards.* This method requires the use of a PCI-Express, AGP, or a PCI expansion slot but provides the highest possible level of performance, the greatest amount of memory, and the largest choice of features.
- *Video-only chipset on the motherboard.* Performance is generally less than with add-on video cards because older chipset designs are often used. Although many systems with the LPX design used this type of video, it has fallen out of fashion on recent systems. Mid-range and high-end notebook computers typically use a discrete video chip instead of integrated video.
- *Motherboard chipset with integrated video.* This has the lowest cost of any video solution, but performance can also be very low, especially for 3D gaming or other graphics-intensive applications. Resolution and color-depth options are also more limited than those available with add-on video cards. Most low-end and some mid-range notebooks use this type of video instead of a discrete video chip on the motherboard.

Typically, desktop computers that use microATX, FlexATX, microBTX, PicoBTX, or Mini-ITX motherboards feature integrated video using chipsets made by Intel, VIA Technology, SiS, or other vendors. Some microATX or microBTX motherboards might also have a provision for a PCI-Express x16 or AGP video card. For more information, see the next section, "[Integrated Video/Motherboard Chipsets](#)."

▶▶ See "[3D Chipsets](#)," p. [919](#).

The term *video adapter* applies to either integrated or separate video circuitry. The term *graphics adapter* is essentially interchangeable with *video adapter* because all video options developed since the original IBM monochrome display adapter (MDA) can display graphics as well as text.

Integrated Video/Motherboard Chipsets

Although built-in video has been a staple of low-cost computing for a number of years, until the late 1990s most motherboard-based video simply moved the standard video components discussed earlier in this chapter to the motherboard. Many low-cost systems especially those using the semiproprietary LPX motherboard form factor have incorporated standard VGA-type video circuits on the motherboard. The performance and features of the built-in video differed only slightly from add-on cards using the same or similar chipsets, and in most cases the built-in video could be replaced by adding a video card. Some motherboard-based video also had provisions for memory upgrades.

◀◀ See "[LPX](#)," p. [221](#).

However, in recent years the move toward increasing integration on the motherboard has led to the development of chipsets that include 3D accelerated video and audio support as part of the chipset design. In effect, the motherboard chipset takes the place of most of the video card components listed earlier and uses a portion of main system memory as video memory. The use of main system memory for video memory is often referred to as *unified memory architecture (UMA)*, and although this memory-sharing method was also used by some built-in video that used its own chipset, it has become much more common

with the rise of integrated motherboard chipsets.

The pioneer of integrated chipsets containing video (and audio) features was Cyrix (now owned by VIA Technologies). While Cyrix was owned by National Semiconductor, it developed a two-chip product called MediaGX. MediaGX incorporated the functions of a CPU, memory controller, sound, and video and made very low-cost computers possible (although with performance significantly slower than that of Pentium-class systems with similar clock speeds). National Semiconductor retained the MediaGX after it sold Cyrix to VIA Technologies. National Semiconductor went on to develop improved versions of the MediaGX, called the Geode GX1 and Geode GX2, for use in thin clients (a terminal that runs Windows and has a high-res display), interactive set-top boxes, and other embedded devices. National Semiconductor sold its information appliance business, including the Geode family, to Advanced Micro Devices (AMD) in August 2003. AMD currently offers a variety of Geodebased solutions.

Intel became the next major player to develop integrated chipsets, with its 810 chipset for the Pentium III and Celeron processors. The 810 (codenamed Whitney before its official release) heralded the beginning of widespread industry support for this design. Intel later followed the release of the 810 series (810 and 810E) with the 815 series for the Pentium III and Celeron, most of which also feature integrated video. Currently, Intel offers integrated video for the Pentium 4 and Celeron 4 processors in the 845, 865, and 91x chipset families; the 9xx chipsets also support the dual-core Pentium D and Pentium Extreme Edition processors. [Table 13.9](#) compares the major video features of Intel's 8xx and 9xx series chipsets, which include integrated video. Note that chipsets listed together share the same video features but differ in other ways such as memory support, I/O features, and so forth.

Table 13.9. Integrated Video Features of Intel 8xx/9xx Chipsets

Chipset	Supported Processors	Integrated Graphics Type	External AGP Graphics Support	Video Memory Size
810, 810E, 810E2	Pentium III, Celeron III	Intel 3D with Direct AGP		6MB ^[1] , 10MB ^[2] , 12MB ^[3]
815, 815E	Pentium III, Celeron III	Intel 3D with Direct AGP	AGP 4x	6MB ^[1] , 10MB ^[2] , 12MB ^[3]
815G, 815EG	Pentium III, Celeron III	Intel 3D with Direct AGP		6MB ^[1] , 10MB ^[2] , 12MB ^[3]
845GL	Pentium 4, Celeron 4	Intel Extreme Graphics		32MB ^[4] , 64MB ^[5]
845G, 845GE	Pentium 4, Celeron 4	Intel Extreme Graphics	AGP 4x	32MBs ^[6] , 64MB ^[7]

845GV	Pentium 4, Celeron 4	Intel Extreme Graphics		32MB ^[6] , 64MB ^[7]
865GV	Pentium 4, Celeron 4, Celeron D	Intel Extreme Graphics 2		32MB ^[4] , 64MB ^[5]
865G	Pentium 4, Celeron 4, Celeron D	Intel Extreme Graphics 2	AGP 8x	32MB ^[4] , 64MB ^[5]
910GL ^[8]	Pentium 4, Celeron 4, Celeron D	Intel Graphics Media Accelerator 900		32MB ^[4] , up to 128MB ^[5]
915G ^[8]	Pentium 4, Celeron 4, Celeron D	Intel Graphics Media Accelerator 900	PCI Express x16	32MB ^[4] , up to 128MB ^[5]
915GV, 915GL ^[8]	Pentium 4, Celeron 4, Celeron D	Intel Graphics Media Accelerator 900		32MB ^[4] , up to 128MB ^[5]
945G	Pentium D, Pentium 4, Celeron D, Celeron 4	Intel Graphics Media Accelerator 950	PCI Express x16	Up to 224MB ^[9]
945GZ	Pentium D, Pentium 4, Celeron D, Celeron 4	Intel Graphics Media Accelerator 950		Up to 224MB ^[9]

Intel 3D with Direct AGPBasic 2D and 3D acceleration.

Intel Extreme GraphicsSupports alpha blending, fog, anisotropic filtering, hardware motion compensation, and advanced textures.

Intel Extreme Graphics 2Enhanced version of original Extreme Graphics, adding better memory management, zone rendering, and faster pixel and texturing rendering.

Intel Graphics Media Accelerator 900Originally known as Extreme Graphics 3, this is an enhanced version of Extreme Graphics 2, adding support for most DirectX 9 features (does not support vertex shaders), optional dualdisplay support (requires ADD2 card), and support for wide-screen LCD panels.

Intel Graphics Media Accelerator 950A faster version of Intel Graphics Media Accelerator 900.

^[1] Systems with 32MB of RAM, PV 5.x, or greater graphics drivers.

^[2] Systems with 64MB of RAM, PV 5.x, or greater graphics drivers.

^[3] Systems with 128MB or more of RAM, PV 5.x, or greater graphics drivers.

^[4] Systems with up to 128MB of RAM.

^[5] Systems with more than 128MB of RAM.

^[6] *Systems with up to 255MB of RAM.*

^[7] *Systems with 256MB or more of RAM.*

^[8] *This family of chipsets was code-named Grantsdale before its release.*

^[9] *Amount of memory actually used varies by task and onboard system memory. See Intel's website for details.*

See "[Intel 810, 810E, and 810E2](#)," p. [268](#); "[Intel 815 Family](#)," p. [271](#); "[Intel 845 Family](#)," p. [286](#); "[Intel 865 Family](#)," p. [288](#); and "[Intel 945 Express Family](#)," p. [290](#).

Besides Intel, other major vendors of integrated chipsets include NVIDIA, VIA, ATI, and Acer Labs. [Table 13.10](#) compares the video features of major integrated chipsets from these vendors that support current AMD and Intel processors.

Table 13.10. Video Features of Non-Intel Integrated Chipsets for Current Intel and AMD Processors

Vendor	Chipset	Supported Processors	Integrated Graphics Type	External Graphics Support	Video Memory Size
ATI	Radeon IGP 9100	Intel Pentium 4, Celeron 4	ATI Radeon 9000	AGP 8x	Up to 128MB
ATI	Radeon IGP 9100 PRO	Intel Pentium 4, Celeron 4	ATI Radeon 9000	AGP 8x	Up to 128MB
ATI	Radeon Xpress 200 for Intel	Intel Pentium 4, Celeron 4	ATI Radeon X300	PCI Express x16	Up to 256MB
ATI	Radeon Xpress 200 for AMD	AMD Athlon 64 family (including Socket 754 Sempron)	ATI Radeon X300	PCI Express x16	Up to 128MB
ATI	Radeon IGP 320	AMD Athlon XP	ATI Radeon VE	AGP 4x	Up to 64MB
NVIDIA	nForce2	AMD Athlon/Duron/Athlon XP	NVIDIA GeForce4 MX420	AGP 8x	Up to 64MB
SIS	SiS661FX	Intel Pentium 4, Pentium D, Celeron 4	SiS Ultra-AGP II Mirage	AGP 8x	Up to 64MB

SiS	SiS661GX	Intel Pentium 4, Pentium D, Celeron 4	SiS Ultra-AGP II Mirage	AGP 8x	Up to 64MB
SiS	SiS761GL	AMD Athlon 64, Sempron (Socket 754)	SiS Mirage 1	AGP 8x	Up to 64MB
SiS	SiS761GX	AMD Athlon 64 FX	SiS Mirage 1	PCI Express x16	Up to 128MB
SiS	SiS760	AMD Athlon 64, Opteron	SiS Mirage 2	AGP 8x	Up to 128MB
SiS	SiS741	AMD Athlon XP/ Athlon/Duron	SiS Ultra-AGP II Mirage	AGP 8x	Up to 64MB
VIA	P4M800 Pro, P4M800	Intel Pentium 4, Celeron 4	S3 Graphics Unichrome Pro	AGP 8x	Up to 64MB
VIA	K8M800	AMD Athlon 64, Opteron	S3 Graphics Unichrome Pro	AGP 8x	Up to 64MB
VIA	K8M890	AMD Athlon 64, Sempron (Socket 754)	S3 Graphics DeltaChrome	PCI-Express x16	64MB or more
VIA	KM400	AMD Athlon XP/ Athlon/Duron	S3 Graphics Unichrome	AGP 8x	Up to 64MB

To learn more about the integrated graphics included with a given chipset, refer to the appropriate section following the "[Chipsets](#)" heading on p. [253](#).

Although a serious 3D gamer will not be satisfied with the performance of most integrated chipsets (ATI's Radeon Xpress 200 IGPs being notable exceptions), business, home/office, and casual gamers will find that integrated chipset-based video on Pentium 4, Athlon XP, or Athlon 64 platforms are satisfactory in performance and provide cost savings compared with separate video cards. If you decide to buy a motherboard with an integrated chipset, I recommend that you select one that also supports an AGP 8x or PCI Express x16 video expansion slot. This enables you to add a faster video card in the future if you decide you need it.

Video Adapter Components

All video display adapter cards contain certain basic components, such as the following:

- Video BIOS.
- Video processor/video accelerator.
- Video memory.
- Digital-to-analog converter (DAC). Formerly a separate chip, the DAC is usually incorporated into the video processor/accelerator chip on recent chipsets. The DAC is not necessary on a purely digital subsystem (digital video card and display), but because most display subsystems have an analog VGA video card, an analog display, or both, video cards will continue to have DAC features for some

time to come.

- Bus connector.
- Video driver.

[Figure 13.14](#) indicates the locations of many of these components on a typical PCI Express x16 video card. Note that the acronym GPU refers to the graphics processing unit.

Figure 13.14. A typical example of a high-end video card based on the NVIDIA GeForce 7800 GTX, a GPU optimized for gaming and dual-display support.

- | | |
|--|---|
| 1. TV-out (S-video) | 5. Copper heatsinks over GDDR3 memory chips |
| 2. DVI-out (can be converted to VGA-out) | 6. Connector to system power supply |
| 3. Fan power connector | 7. Cooling fan over GPU |
| 4. PCI Express x16 slot connector | 8. Connector for MIO (SLI bridge) |

Virtually all video adapters on the market today use chipsets that include 3D acceleration features. The following sections examine these components and features in greater detail.

The Video BIOS

Video adapters include a BIOS that is similar in construction but completely separate from the main system BIOS. (Other devices in your system, such as SCSI adapters, might also include their own BIOS.) If you turn on your monitor first and look quickly, you might see an identification banner for your adapter's video

BIOS at the very beginning of the system startup process.

Similar to the system BIOS, the video adapter's BIOS takes the form of a ROM (read-only memory) chip containing basic instructions that provide an interface between the video adapter hardware and the software running on your system. The software that makes calls to the video BIOS can be a stand-alone application, an operating system, or the main system BIOS. The programming in the BIOS chip enables your system to display information on the monitor during the system POST and boot sequences, before any other software drivers have been loaded from disk.

◀◀ See "[BIOS Basics](#)," p. [412](#).

The video BIOS also can be upgraded, just like a system BIOS, in one of two ways. The BIOS uses a rewritable chip called an EEPROM (electrically erasable programmable read-only memory) that you can upgrade with a utility the adapter manufacturer provides. On very old cards, you might be able to completely replace the chip with a new one again, if supplied by the manufacturer and if the manufacturer did not hard solder the BIOS to the printed circuit board. Most recent video cards use a surface-mounted BIOS chip rather than a socketed chip. A BIOS you can upgrade using software is referred to as a *flash* BIOS, and most current-model video cards that offer BIOS upgrades use this method. However, most vendors now prefer to update drivers rather than perform BIOS updates to fix card problems.

Video BIOS upgrades (sometimes referred to as *firmware* upgrades) are sometimes necessary in order to use an existing adapter with a new operating system, or when the manufacturer encounters a significant bug in the original programming. Occasionally, a BIOS upgrade is necessary because of a major revision to the video card chipset's video drivers. As a general rule, the video BIOS is a component that falls into the "if it ain't broke, don't fix it" category. Try not to let yourself be tempted to upgrade just because you've discovered that a new BIOS revision is available. Check the documentation for the upgrade, and unless you are experiencing a problem with the upgrade addresses, leave it alone.

◀◀ See "[Video Adapter BIOS](#)," p. [538](#).

The Video Processor

The video processor (also known as the video chipset, video graphics processor, or GPU) is the heart of any video adapter and essentially defines the card's functions and performance levels. Two video adapters built using the same chipset often have many of the same capabilities and deliver comparable performance. Also, the software drivers that operating systems and applications use to address the video adapter hardware are written primarily with the chipset in mind. You often can use a driver intended for an adapter with a particular chipset on any other adapter using the same chipset. Of course, cards built using the same chipset can differ in the amount and type of memory installed, so performance can vary.

Since the first VGA cards were developed, several main types of processors have been used in video adapters; these technologies are compared in [Table 13.11](#).

Table 13.11. Video Processor Technologies

Processor Type	Where Video Processing Takes Place	Relative Speed	Relative Cost	How Used Today
Frame-buffer	Computer's CPU.	Very slow	Very low	Obsolete; mostly ISA video cards
Graphics coprocessor	Video card's own processor.	Very fast	Very high	CAD and engineering workstations
Graphics accelerator	Video chip draws lines, circles, shapes; CPU sends commands to draw them.	Fast	Low to moderate	All mainstream video cards; is combined with 3D GPU on current cards
3D graphics processor (GPU)	Video card's 3D GPU (in accelerator chipset) renders polygons and adds lighting and shading effects as needed.	Fast 2D and 3D display	Most price ranges depending on chipset, memory, and RAMDAC speed	All mainstream video cards

Identifying the Video and System Chipsets

Before you purchase a system or a video card, you should find out which chipset the video card or video circuit uses or, for systems with integrated chipset video, which integrated chipset the system uses. This allows you to have the following:

- Better comparisons of card or system to others
- Access to technical specifications
- Access to reviews and opinions
- Better buying decisions
- Choice of card manufacturer or chipset manufacturer support and drivers

Because video card performance and features are critical to enjoyment and productivity, find out as much as you can before you buy the system or video card by using the chipset or video card manufacturer's website and third-party reviews. Poorly written or buggy drivers can cause several types of problems, so be sure to check periodically for video driver updates and install any that become available. With video cards, support after the sale can be important. So, you should check the manufacturer's website to see whether it offers updated drivers and whether the product seems to be well supported.

The Vendor List on the disc has information on most of the popular video chipset manufacturers, including how to contact them. You should note that NVIDIA (the leading video chipset vendor) makes only chipsets, whereas ATI (the #2 video vendor) makes branded video cards and supplies chipsets to vendors. This means a wide variety of video cards use the same chipset; it also means that you are likely to find variations in card performance, software bundles, warranties, and other features between cards using the same chipset.

Video RAM

Most video adapters rely on their own onboard memory that they use to store video images while processing them; although the AGP specification supports the use of system memory for 3D textures, this feature is seldom supported now that video cards routinely ship with as much as 256MB or more onboard memory and with the move away from AGP to PCI Express x16 video cards. Many low-cost systems with onboard video use the universal memory architecture (UMA) feature to share the main system memory. In any case, the memory on the video card or borrowed from the system performs the same tasks.

The amount of memory on the adapter or used by integrated video determines the maximum screen resolution and color depth the device can support. You often can select how much memory you want on a particular video adapter; for example, 128MB, 256MB, and 512MB are common choices today. Although adding more memory is not guaranteed to speed up your video adapter, it can increase the speed if it enables a wider bus (for example, from 128 bits wide to 256 bits wide) or provides nondisplay memory as a cache for commonly displayed objects. It also enables the card to generate more colors and higher resolutions and, for AGP cards, allows 3D textures to be stored and processed on the card, rather than in slower main memory.

Many types of memory have been used with video adapters. These memory types are summarized in [Table 13.12](#).

Table 13.12. Memory Types Used in Video Display Adapters

Memory Type	Definition	Relative Speed	Usage
FPM DRAM	Fast Page-Mode RAM	Slow	Low-end ISA cards; obsolete
VRAM ^[1]	Video RAM	Fast	Expensive; obsolete
WRAM ^[1]	Window RAM	Fast	Expensive; obsolete
EDO DRAM	Extended Data Out DRAM	Moderate	Low-end PCI-bus
SDRAM	Synchronous DRAM	Fast	Low-end PCI/AGP
MDRAM	Multibank DRAM	Fast	Little used; obsolete
SGRAM	Synchronous Graphics DRAM	Very fast	High-end PCI/AGP; replaced by DDR SDRAM
DDR SDRAM	Double-Data Rate SDRAM	Very fast	High-end AGP
DDR-II SDRAM	DDR SDRAM, 4-bit per-cycle memory fetch	Extremely fast	High-end AGP, PCI Express
GDDR-3 SDRAM	Modified DDR SDRAM	Extremely fast	High-end AGP, PCI Express

^[1] VRAM and WRAM are dual-ported memory types that can read from one port and write data through the other port. This improves performance by reducing wait times for accessing the video RAM compared to FPM DRAM and EDO DRAM.

Note

To learn more about memory types used on older video cards (FPD DRAM, VRAM, WRAM, EDO DRAM, and MDRAM), see [Chapter 15](#) of *Upgrading and Repairing PCs, 12th Edition*, available in electronic form on the disc packaged with this book.

SGRAM, SDRAM, DDR, DDR2 SDRAM, and GDDR3 SDRAM which are derived from popular motherboard memory technologies have replaced VRAM, WRAM, and MDRAM as high-speed video RAM solutions. Their high speeds and low production costs have enabled even inexpensive video cards to have 64MB or more of high-speed RAM onboard.

SDRAM

Synchronous DRAM (SDRAM) is the same type of RAM used on many current systems based on processors such as the Pentium III, Pentium 4, Athlon, and Duron. The SDRAMs found on video cards are usually surface-mounted individual chips; on a few early models, a small module containing SDRAMs might be plugged in to a proprietary connector. This memory is designed to work with bus speeds up to 200MHz and provides performance just slightly slower than SGRAM. SDRAM is used primarily in older AGP 2x/4x low-end video cards and chipsets such as NVIDIA's GeForce2 MX and ATI's Radeon VE.

SGRAM

Synchronous Graphics RAM (SGRAM) was designed to be a high-end solution for very fast video adapter designs. SGRAM is similar to SDRAM in its capability to be synchronized to high-speed buses up to 200MHz, but it differs from SDRAM by including circuitry to perform block writes to increase the speed of graphics fill or 3D Z-buffer operations. Although SGRAM is faster than SDRAM, most video card makers have dropped SGRAM in favor of even faster DDR SDRAM in their newest products.

DDR SDRAM

Double Data Rate SDRAM (also called DDR SDRAM) is the most common video RAM technology on recent video cards. It is designed to transfer data at speeds twice that of conventional SDRAM by transferring data on both the rising and falling parts of the processing clock cycle. Today's mid-range and low-end video cards based on chipsets such as NVIDIA's GeForce FX and ATI's Radeon 9xxx and X300/600 series use DDR SDRAM for video memory.

DDR2 SDRAM

The second generation of DDR SDRAM fetches 4 bits of data per cycle, instead of 2 as with DDR SDRAM. This doubles performance at the same clock speed. The first video chipset to support DDR2 was NVIDIA's GeForce FX, which became the top of NVIDIA's line of GPUs in late 2002.

GDDR3 SDRAM

GDDR3 SDRAM, which began appearing on NVIDIA's high-end graphics cards in early 2004 and is used by ATI's X800 and higher series of AGP and PCI-Express cards, is based on DDR2 memory, but with two major

differences:

- GDDR3 separates reads and writes with a single-ended unidirectional strobe, whereas DDR2 uses differential bidirectional strobes. This method enables much higher data transfer rates.
- GDDR3 uses an interface technique known as *pseudo-open drain*, which uses voltage instead of current. This method makes GDDR3 memory compatible with GPUs designed to use DDR or DDR2 memory.

◀◀ For more information about DDR, DDR2, and GDDR3, see [Chapter 6](#), "Memory," p. [471](#).

Video RAM Speed

Video RAM speed is typically measured in MHz, and video card makers often match different memory speeds with different versions of the same basic GPU, as with NVIDIA's GeForce 6800 (300MHz DDR) and GeForce 6800 Ultra (550MHz DDR) memory. Faster memory and faster GPUs produce better gaming performance, but at a higher cost. However, if you are primarily concerned about business or productivity application performance, you can save money by using a video card with a slower GPU and slower memory.

Unless you dig deeply into the technical details of a particular 3D graphics card, determining whether a particular card uses SDRAM, DDR SDRAM, DDR2, SGRAM, or GDDR3 can be difficult. Because none of today's 3D accelerators feature upgradeable memory, I recommend that you look at the performance of a given card and choose the card with the performance, features, and price that's right for you.

RAM Calculations

The amount of memory a video adapter needs to display a particular resolution and color depth is based on a mathematical equation. A location must be present in the adapter's memory array to display every pixel on the screen, and the resolution determines the number of total pixels. For example, a screen resolution of 1024x768 requires a total of 786,432 pixels.

If you were to display that resolution with only two colors, you would need only 1 bit of memory space to represent each pixel. If the bit has a value of 0, the dot is black, and if its value is 1, the dot is white. If you use 24 bits of memory space to control each pixel, you can display more than 16.7 million colors because 16,777,216 combinations are possible with a 4-digit binary number ($2^{24}=16,777,216$). If you multiply the number of pixels necessary for the screen resolution by the number of bits required to represent each pixel, you have the amount of memory the adapter needs to display that resolution. Here is how the calculation works:

$$\begin{aligned}
 1024 \times 768 &= 786432 \text{ pixels} \times 24 \text{ bits per pixel} \\
 &= 18,874,368 \text{ bits} \\
 &= 2,359,296 \text{ bytes} \\
 &= 2.25\text{MB}
 \end{aligned}$$

As you can see, displaying 24-bit color (16,777,216 colors) at 1024x768 resolution requires exactly 2.25MB of RAM on the video adapter. Because most adapters support memory amounts of only 256KB, 512KB, 1MB, 2MB, or 4MB, you would need to use a video adapter with at least 4MB of RAM onboard to run your system using that resolution and color depth.

To use the higher-resolution modes and greater numbers of colors common today, you would need much more memory on your video adapter than the 256KB found on the original IBM VGA. [Table 13.13](#) shows the memory requirements for some of the most common screen resolutions and color depths used for 2D graphics operations, such as photo editing, presentation graphics, desktop publishing, and web page design.

Table 13.13. Video Display Adapter Minimum Memory Requirements for 2D Operations

Resolution	Color Depth	Max. Colors	Memory Required	Memory Used
640x480	16-bit	65,536	1MB	614,400 bytes
640x480	24-bit	16,777,216	1MB	921,600 bytes
640x480	32-bit	4,294,967,296	2MB	1,228,800 bytes
800x600	16-bit	65,536	1MB	960,000 bytes
800x600	24-bit	16,777,216	2MB	1,440,000 bytes
800x600	32-bit	4,294,967,296	2MB	1,920,000 bytes
1024x768	16-bit	65,536	2MB	1,572,864 bytes
1024x768	24-bit	16,777,216	4MB	2,359,296 bytes
1024x768	32-bit	4,294,967,296	4MB	3,145,728 bytes
1280x1024	16-bit	65,536	4MB	2,621,440 bytes
1280x1024	24-bit	16,777,216	4MB	3,932,160 bytes
1280x1024	32-bit	4,294,967,296	8MB	5,242,880 bytes
1400x1050	16-bit	65,536	4MB	2,940,000 bytes
1400x1050	24-bit	16,777,216	8MB	4,410,000 bytes
1400x1050	32-bit	4,294,967,296	8MB	5,880,000 bytes
1600x1200	16-bit	65,536	4MB	3,840,000 bytes
1600x1200	24-bit	16,777,216	8MB	5,760,000 bytes
1600x1200	32-bit	4,294,967,296	8MB	7,680,000 bytes

As you can see from [Table 13.13](#), any current graphics card or integrated graphics solution has more than enough memory to provide true color (24-bit or 32-bit) rendition at any popular resolution. Current video cards and integrated graphics solutions provide much more memory than the amounts listed in [Table 13.13](#) because of the additional memory needs of 3D operation.

3D video cards require more memory for a given resolution and color depth because the video memory

must be used for three buffers: the front buffer, back buffer, and Z-buffer. The amount of video memory required for a particular operation varies according to the settings used for the color depth and Z-buffer. Triple buffering allocates more memory for 3D textures than double buffering but can slow down performance of some games. The buffering mode used by a given 3D video card usually can be adjusted through its properties sheet.

[Table 13.14](#) lists the memory requirements for 3D cards in selected modes.

Table 13.14. Video Display Adapter Memory Requirements for 3D Operations

Resolution	Color Depth	Z-Buffer Depth	Buffer Mode	Actual Memory Used	Onboard Video Memory Size Required
640x480	16-bit	16-bit	Double	1.76MB	2MB
			Triple	2.34MB	4MB

Note

Although 3D adapters typically operate in a 32-bit mode (refer to [Table 13.13](#)), this does not necessarily mean they can produce more than the 16,277,216 colors of a 24-bit true-color display. Many video processors and video memory buses are optimized to move data in 32-bit words, and they actually display 24-bit color while operating in a 32-bit mode, instead of the 4,294,967,296 colors you would expect from a true 32-bit color depth.

Although current integrated graphics solutions feature 3D support, the performance they offer is limited by several factors, including

- *Lack of memory.* Most integrated 3D implementations do not provide more than 128MB of RAM. For best 3D performance, you should use a video card with 256MB of RAM or more. Some high-end cards now support up to 512MB of RAM.
- *Narrow data bus.* Because integrated graphics solutions share video memory with the processor, they use the same data bus as the processor. In a single-channel-based system, this restricts the data bus to 64 bits. A dual-channel system has a 128-bit data bus, but today's fastest 3D video cards have up to a 512-bit data bus. The wider the data bus, the faster graphics data can be manipulated.
- *Lack of full DirectX 9 support.* Most integrated graphics solutions support only some DirectX 9 features or support DirectX 9 with slow software emulation rather than with hardware.

For these reasons, you are likely to be disappointed (and lose a lot of games!) if you play 3D games using integrated graphics. To enjoy 3D games and give yourself a fighting chance of winning, opt for a mid-range to high-end 3D video card based on a current ATI or NVIDIA chipset with 256MB of RAM or more. If your budget permits, you might also consider using a dual-card solution from ATI or NVIDIA that allows you to use two high-end video cards to double your graphics processing performance.

See "[Dual-GPU Scene Rendering](#)," p. [916](#).

Note

If your system uses integrated graphics and you have less than 256MB of RAM, you might be able to increase your available graphics memory by upgrading system memory (system memory is used by the integrated chipset). Most recent Intel chipsets with integrated graphics automatically detect additional system memory and adjust the size of graphics memory automatically. Refer to [Table 13.9](#) for details.

Why Won't Windows Display More Than 256 Colors?

If you have a video card with 1MB or more of video memory, but the Windows Display Settings properties sheet won't allow you to select a color depth greater than 256 colors, Windows might have misidentified the video card during installation or the video driver installation might be corrupted. To see which video card Windows recognizes, click the Advanced Properties button, and then click the Adapter tab if necessary. Your adapter type might be listed either by the video card's brand name and model or by the video card's chipset maker and chipset model.

If the card model or chipset appears to be incorrect or not specific enough, click Change and see what other drivers your system lists that appear to be compatible, or use a utility program provided by your video card/chipset maker to identify your card and memory size. Then, manually select the correct driver if necessary. If the video card model or chipset appears to be correct, open the System properties sheet, locate the Device Manager, and remove the display adapter listing. Restart the computer and Windows will redetect the video card/chipset and install the correct driver.

Video Bus Width

Another issue with respect to the memory on the video adapter is the width of the bus connecting the graphics chipset and memory on the adapter. The chipset is usually a single large chip on the card that contains virtually all the adapter's functions. It is wired directly to the memory on the adapter through a local bus on the card. Most of the high-end adapters use an internal memory bus that is 256 or 512 bits wide. This jargon can be confusing because video adapters that take the form of separate expansion cards also plug in to the main system bus, which has its own speed rating. When you read about a 128-bit or 256-bit video adapter, you must understand that this refers to the local video bus and that the bus connecting the adapter to the system is actually the PCI, AGP, or PCI-Express bus on the system's motherboard.

◀◀ See "[System Bus Types, Functions, and Features](#)," p. [352](#).

The Digital-to-Analog Converter

The digital-to-analog converter on a video adapter (commonly called a RAMDAC) does exactly what its name describes. The RAMDAC is responsible for converting the digital images your computer generates into analog signals the monitor can display. The speed of the RAMDAC is measured in MHz; the faster the conversion process, the higher the adapter's vertical refresh rate. The speeds of the RAMDACs used in today's high-performance video adapters range from 300MHz to 500MHz. Most of today's video card chipsets include the RAMDAC function inside the 3D accelerator chip, but some dual-displaycapable video cards use a separate RAMDAC chip to allow the second display to work at different refresh rates than the primary display. Systems that use integrated graphics include the RAMDAC function in the North Bridge or GMCH chip portion of the motherboard chipset.

The benefits of increasing the RAMDAC speed include higher vertical refresh rates, which allows higher resolutions with flicker-free refresh rates (72Hz/85Hz or above). Typically, cards with RAMDAC speeds of 300MHz or above display flicker-free (75Hz or above) at all resolutions up to 1920x1200. Of course, as discussed earlier in this chapter, you must ensure that any resolution you want to use is supported by both your monitor and video card.

The Bus

You've learned in this chapter that certain video adapters were designed for use with certain system buses. Earlier bus standards, such as the IBM MCA, ISA, EISA, and VL-Bus, have all been used for VGA and other video standards. Because of their slow performances, all are now obsolete; current video cards use the PCI, AGP, or PCI-Express bus standard.

In current and forthcoming systems, PCI Express x16 is the standard video card slot design, replacing the long-time standard AGP 8x. Some systems can support both types of video cards, enabling you to move to PCI Express x16 at your own pace. PCI video cards are limited in quantity and performance and are sold primarily as upgrades for systems with integrated video that lack AGP or PCI Express slots.

◀◀ See "[The PCI Bus](#)," p. [372](#).

◀◀ See "[PCI-Express](#)," p. [376](#).

◀◀ See "[Accelerated Graphics Port](#)," p. [378](#).

AGP Video Cards

The Accelerated Graphics Port (AGP), an Intel-designed dedicated video bus introduced in 1997, delivers a maximum bandwidth up to 16 times larger than that of a comparable PCI bus. AGP has been the mainstream high-speed video standard for several years but is now being replaced by the more versatile and faster PCI Express x16 standard.

The AGP slot is essentially an enhancement to the existing PCI bus; however, it's intended for use only with video adapters and provides them with high-speed access to the main system memory array. This enables the adapter to process certain 3D video elements, such as texture maps, directly from system memory rather than having to copy the data to the adapter memory before the processing can begin. This saves time and eliminates the need to upgrade the video adapter memory to better support 3D functions. Although AGP version 3.0 provides for two AGP slots, this feature has never been implemented in practice. Systems with AGP have only one AGP slot.

Note

Although the earliest AGP cards had relatively small amounts of onboard RAM, most recent and all current implementations of card-based AGP use large amounts of on-card memory and use a memory aperture (a dedicated memory address space above the area used for physical memory) to transfer data more quickly to and from the video card's own memory. Integrated chipsets featuring built-in AGP do use system memory for all operations, including texture maps. Ironically, the memory aperture used by AGP cards can actually cause out-of-memory errors with Windows 9x and Windows Me on systems with more than 512MB of RAM. See Microsoft Knowledge Base document #253912 for details at <http://support.microsoft.com>.

Although AGP was introduced during the same time period in which Windows NT 4.0 and Windows 95 were the current versions of Windows, those versions of Windows do not support AGP's Direct Memory Execute (DIME) feature. DIME uses main memory instead of the video adapter's memory for certain tasks to lessen the traffic to and from the adapter. Windows 98/Me and Windows 2000/XP support this feature. However, with the large amounts of memory found on current AGP video cards, this feature is seldom implemented.

Four speeds of AGP are available: 1X, 2X, 4X, and 8X (see [Table 13.15](#) for details). Most current AGP video cards support AGP 8x and can fall back to AGP 4x or 2x on systems that don't support AGP 8x.

Table 13.15. AGP Speeds and Technical Specifications

AGP Speed	AGP Specification	Clock Speed	Transfer Rate	Slot Voltages
1x	1.0	66MHz	266MBps	3.3V
2x	1.0	133MHz	533MBps	3.3V, 1.5V ^[1]
4x	2.0	266MHz	1066MBps	1.5V
8x	3.0	533MHz	2133MBps	1.5V ^[2]

^[1] *Varies with card implementation.*

^[2] *Uses 0.8V internal signaling.*

Because of the bandwidth AGP 3.0 requires, systems featuring this version of AGP also support DDR333 or faster memory, which is significantly faster than DDR266 (also known as PC2100 memory). AGP 3.0 was announced in 2000, but support for the standard required the development of motherboard chipsets that were not introduced until mid-2002. Almost all current motherboard chipsets with AGP support feature AGP 8x support; however, differences in GPU design, memory bus design, and core and memory clock speed mean (as always) that AGP 8x cards with faster and wider memory and faster GPU speeds provide faster performance than AGP 8x cards with slower and narrower components.

Although some systems with AGP 4x or 8x slots use a universal slot design that can handle 3.3V or 1.5V AGP cards, others do not. If a card designed for 3.3V (2x mode) is plugged in to a motherboard that supports only 1.5V (4x mode) signaling, the motherboard will be damaged.

◀◀ See "[Accelerated Graphics Port](#)," p. [378](#).

Caution

Be sure to check AGP compatibility before you insert an older (AGP 1x/2x) card into a recent or current system. Even if you can physically insert the card, a mismatch between the card's required voltage and the AGP slot's voltage output can damage the motherboard. Check the motherboard manual for the card types and voltage levels supported by the AGP slot.

Some AGP cards can use either 3.3V or 1.5V voltage levels by adjusting an onboard jumper. These cards typically use an AGP connector that is notched for use with either AGP 2x or AGP 4x slots, as pictured in [Chapter 4](#), "Motherboards and Buses." Be sure to set these cards to use 1.5V before using them in motherboards that support only 1.5V signaling, such as motherboards based on the Intel 845 or 850 chipsets.

PCI Express Video Cards

PCI Express, which has largely replaced AGP in new systems, began to show up in high-performance systems in mid-2004 and has filtered down to almost all systems that use discrete video cards or have integrated video that can be upgraded. Despite the name, PCI Express uses a high-speed bidirectional serial data transfer method, and PCI Express channels (also known as *lanes*) can be combined to create wider and faster expansion slots (each lane provides 250MBps data rate in each direction). Unlike PCI, PCI Express slots do not compete with each other for bandwidth. PCI Express graphics cards use 16 lanes (x16) to enable speeds of 4GBps in each direction; when PCI Express is used for other types of cards, fewer lanes are used.

PCI, AGP, and x16 PCI Express have some important differences, as [Table 13.16](#) shows.

Table 13.16. High-Speed Video Card Bus Specifications

Feature	PCI	AGP	PCI Express
Theoretical maximum	133MBps ^[1]	533MBps throughput (2X) 1066MBps throughput (4X) ^[2] 2133MBps throughput (8X) ^[2]	250MBps/lane ^[3] 4GBps (x16) ^[3]
Slots ^[2]	4/5 (typical)	1	1/more ^[4]

^[1] At 33MHz bus speed and 32 bits.

^[2] Most current systems support AGP 4X/8X only.

^[3] In each direction; multiply by 2 for bidirectional throughput.

^[4] *Typical PCI Express implementations include one x16 slot for video and two or more x1 slots for other add-on cards, as well as legacy PCI slots. Systems that support NVIDIA's SLI or ATI's CrossFire dual PCI Express video card technologies have two PCI Express video slots running at x8 or x16 speed.*

The Video Driver

The software driver is an essential, and often problematic, element of a video display subsystem. The driver enables your software to communicate with the video adapter. You can have a video adapter with the fastest processor and the most efficient memory on the market but still have poor video performance because of a badly written driver.

Video drivers generally are designed to support the processor on the video adapter. All video adapters come equipped with drivers the card manufacturer supplies, but often you can use a driver the chipset maker created as well. Sometimes you might find that one of the two provides better performance than the other or resolves a particular problem you are experiencing.

Most manufacturers of video adapters and chipsets maintain websites from which you can obtain the latest drivers; drivers for chipset-integrated video are supplied by the system board or system vendor. A driver from the chipset manufacturer can be a useful alternative, but you should always try the adapter manufacturer's driver first. Before purchasing a video adapter, you should check out the manufacturer's site and see whether you can determine how up to date the available drivers are. At one time, frequent driver revisions were thought to indicate problems with the hardware, but the greater complexity of today's systems means that driver revisions are a necessity. Even if you are installing a brand-new model of a video adapter, be sure to check for updated drivers on the manufacturer's website for best results.

Note

Although most devices work best with the newest drivers, video cards can be a notable exception. Both NVIDIA and ATI now use unified driver designs, creating a single driver installation that can be used across a wide range of graphics chips. However, in some cases, older versions of drivers sometimes work better with older chipsets than the newest drivers do. If you find that system performance or stability, especially in 3D gaming, drops when you upgrade to the newest driver for your 3D graphics card, revert to the older driver.

The video driver also provides the interface you can use to configure the display your adapter produces. On a Windows 9x/Me/2000/XP system, the Display Control Panel identifies the monitor and video adapter installed on your system and enables you to select the color depth and screen resolution you prefer. The driver controls the options that are available for these settings, so you can't choose parameters the hardware doesn't support. For example, the controls would not allow you to select a 1024x768 resolution with 24-bit color if the adapter had only 1MB of memory.

When you click the Advanced button on the Settings page, you see the Properties dialog box for your particular video display adapter. The contents of this dialog box can vary, depending on the driver and the capabilities of the hardware. Typically, on the General page of this dialog box, you can select the size of the fonts (large or small) to use with the resolution you've chosen. Windows 98/Me/2000 (but not Windows XP) also add a control to activate a convenient feature. The Show Settings Icon on Task Bar check box activates a tray icon that enables you to quickly and easily change resolutions and color depths without having to open the Control Panel. This feature is often called QuickRes. The Adapter page displays detailed information about your adapter and the drivers installed on the system, and it enables you to set the

refresh rate for your display; with Windows XP, you can use the List All Modes button to view and choose the resolution, color depth, and refresh rate with a single click. The Monitor page lets you display and change the monitor's properties and switch monitor drivers if necessary. In Windows XP, you can also select the refresh rate on this screen.

If your adapter includes a graphics accelerator, the Performance page contains a Hardware Acceleration slider you can use to control the degree of graphic display assistance provided by your adapter hardware. In Windows XP, the Performance page is referred to as the Troubleshoot page.

Setting the Hardware Acceleration slider to the Full position activates all the adapter's hardware acceleration features. The necessary adjustments for various problems can be seen in [Table 13.17](#) for Windows XP and in [Table 13.18](#) for other versions of Windows.

Table 13.17. Using Graphics Acceleration Settings to Troubleshoot Windows XP

Acceleration Setting	When to Use	Effect of Setting	Long-Term Solution
Left ^[*]	The display works in Safe or VGA but is corrupted in other modes.	There's no acceleration.	Update display, DirectX, and mouse drivers.
One click from left ^[*]	2D and 3D graphics driver problems; mouse driver problems.	It disables all but basic acceleration.	Update display, DirectX, and mouse drivers.
Two clicks from left ^[*]	3D acceleration problems.	It disables DirectX, DirectDraw, and Direct 3D acceleration (mainly used by 3D games).	Update DirectX drivers.
Two clicks from right ^[*]	Display driver problems.	It disables cursor and drawing accelerations.	Update display drivers.
One click from right ^[*]	Mouse pointer corruption.	It disables mouse and pointer acceleration.	Update mouse drivers.
Right	Normal operation.	It enables full acceleration.	N/A

^[*] Disable write combining, which is a method for speeding up screen display, whenever you select any setting other than full acceleration to improve stability. Reenable write combining after you install updated drivers and retry.

Table 13.18. Using Graphics Acceleration Settings to Troubleshoot Other Windows Versions

Mouse Pointer Location

	When to Use	Effects of Setting	Long-Term Solution
Left	Display works in Safe or VGA mode, but it is corrupted in other modes.	It disables all acceleration.	Update display and mouse drivers.
One click from left	2D and 3D graphics driver problems, mouse driver problems.	Basic acceleration only.	Update display and mouse drivers.
One click from right	Mouse pointer corruption.	It disables mouse pointer acceleration.	Update mouse drivers.
Right	Normal operation.	Full acceleration.	N/A

If you're not certain of which setting is the best for your situation, use this procedure: Move the slider one notch to the left to address mouse display problems by disabling the hardware's cursor support in the display driver. This is the equivalent of adding the **SWCursor=1** directive to the **[Display]** section of the **System.ini** file in Windows 9x/Me.

If you are having problems with 2D graphics in Windows XP only, but 3D applications work correctly, move the slider to the second notch from the right to disable cursor drawing and acceleration.

Moving the slider another notch (to the third notch from the right in Windows XP or the second notch from the right in earlier versions) prevents the adapter from performing certain bit-block transfers; it disables 3D functions of DirectX in Windows XP. With some drivers, this setting also disables memory-mapped I/O. This is the equivalent of adding the **Mmio=0** directive to the **[Display]** section of **System.ini** and the **SafeMode=1** directive to the **[Windows]** section of **Win.ini** (and the **SWCursor** directive mentioned previously) in Windows 9x/Me.

Moving the slider to the None setting (the far left) adds the **SafeMode=2** directive to the **[Windows]** section of the **Win.ini** file in Windows 9x/Me. This disables all hardware acceleration support on all versions of Windows and forces the operating system to use only the device-independent bitmap (DIB) engine to display images, rather than bit-block transfers. Use this setting when you experience frequent screen lockups or receive invalid page fault error messages.

Note

If you need to disable any of the video hardware features listed earlier, this often indicates a buggy video or mouse driver. If you download and install updated video and mouse drivers, you should be able to revert to full acceleration. You should also download an updated version of DirectX for your version of Windows.

In most cases, another tab called Color Management is also available. You can select a color profile for your monitor to enable more accurate color matching for use with graphics programs and printers.

Video cards with advanced 3D acceleration features often have additional properties; these are discussed later in this chapter.

Multiple Monitors

Macintosh systems pioneered multiple-monitor support long before Windows, but starting with Windows 98, all current Windows versions also offer the ability to use multiple monitors on a single system. Windows 98/Me support up to 9 monitors (and video adapters), each of which can provide a different view of the desktop. Windows 2000 and Windows XP support up to 10 monitors and video adapters. When you configure a Windows 98/Me or Windows 2000/XP system to use multiple monitors, the operating system creates a virtual desktop that is, a display that exists in video memory that can be larger than the image actually displayed on a single monitor. You use the multiple monitors to display various portions of the virtual desktop, enabling you to place the windows for different applications on separate monitors and move them around at will.

Unless you use multiple-head video cards, each monitor you connect to the system requires its own video adapter. So, unless you have nine bus slots free, the prospects of seeing a nine-screen Windows display are slim, for now. However, even two monitors can be a boon to computing productivity. For example, you can leave an email client or web browser maximized on one monitor and use the other monitor for additional programs.

On a multimonitor Windows system, one display is always considered to be the primary display. The primary display can use any PCI or AGP VGA video adapter that uses a Windows minidriver with a linear frame buffer and a packed (nonplanar) format, meaning that most of the brand-name adapters sold today are eligible. Additional monitors are called secondaries and are much more limited in their hardware support. To install support for multiple monitors, be sure you have only one adapter installed first; then reboot the system, and install each additional adapter one at a time. [Table 13.19](#) lists the multiple-monitor support articles available for Windows 98 and newer versions on the Microsoft support website (<http://support.microsoft.com>).

Table 13.19. Multiple-Monitor Support Articles from the Microsoft Knowledge Base

Article Subject	Windows Versions Supported	Article Number
Video card chipsets with multiple-monitor support	Windows 98	182708
Enabling multiple-monitor support	Windows 98	179602
Troubleshooting multiple displays	Windows 98/Me	182930
Setting up and troubleshooting multiple monitors	Windows 2000	238886
Video card chipsets with multiple-monitor support	Windows XP	296538
Supported display adapters for multiple monitors/ DualView	Windows XP	307397
DualView	Windows XP	283674

It's important that the computer correctly identifies which of the video adapters is the primary one. This is a function of the system BIOS, and if the BIOS on your computer does not let you select which device should be the primary VGA display, it decides based on the order of the PCI slots in the machine. You should, therefore, install the primary adapter in the highest-priority PCI slot. In some cases, an AGP adapter might be considered secondary to a PCI adapter. Depending on the BIOS used by your system, you might need to check in various places for the option to select the primary VGA display. For example, the AMI BIOS used by the MSI KT4 Ultra motherboard for Socket A processors lists this option, which it calls Primary Graphics Adapter, in the PCI/PnP menu. In contrast, the Intel/AMI BIOS used by the Intel D865PERL motherboard lists this option, which it calls Primary Video Adapter, in the Video Configuration menu.

◀◀ See "[The PCI Bus](#)," p. [372](#).

After the hardware is in place, you can configure the display for each monitor from the Display control panel's Settings page. The primary display is always fixed in the upper-left corner of the virtual desktop, but you can move the secondary displays to view any area of the desktop you like. You can also set the screen resolution and color depth for each display individually. Windows XP also supports DualView, an enhancement to Windows 2000's multiple-monitor support. DualView supports the increasing number of dual-head video cards as well as notebook computers connected to external displays. With systems supporting DualView, the first video port is automatically assigned to the primary monitor. On a notebook computer, the primary display is the built-in LCD panel.

Note

Many recent notebook computers that have integrated graphics do not support DualView; however, most recent notebook computers that use a discrete graphics chip do support DualView. To determine whether your notebook computer supports DualView, open its Display properties sheet and click the Settings tab. If two monitor icons are visible, your computer supports DualView. You can activate secondary monitor support after you attach a monitor to the external VGA port.

Even if your BIOS enables you to specify the primary video card and you use video cards that are listed as compatible, determining exactly which display cards will work successfully in a multimonitor configuration can be difficult. Consequently, you should check with your video card or chipset maker for the latest information on Windows 2000 or Windows XP and multiple-monitor support issues.

Because new chipsets, updated drivers, and combinations of display adapters are a continuous issue for multiple-monitor support when separate video cards are used, I recommend the following online resources:

- <http://www.realtimesoft.com/ultramon> is the home of the UltraMon multiple-monitor support enhancement program (\$39.95); an extensive database of user-supplied multiple-monitor configurations for Windows 98/Me, Windows 2000/XP, and Linux; product reviews; and tips
- <http://www.digitalroom.net> (click Tech Articles and then Multiple Monitor Guide); excellent tips on multiple-monitor setups and links to other resources

Multiple-monitor support can be enabled through either of the following:

- Installation of a separate AGP or PCI graphics card for each monitor you want to use
- Installation of a single AGP or PCI graphics card that can support two or more monitors

A card that supports multiple monitors (also called a multiple-head or dual-head card) saves slots inside your system and eliminates the headaches of driver and BIOS updates or system reconfiguration sometimes necessary when using two or more video cards for multiple-monitor capability. Most recent video cards with multiple-monitor support feature a 15-pin analog VGA connector for CRTs, a DVI-I digital/analog connector for digital LCD panels, and a TV-out connector for S-video or composite output to TVs and VCRs. Thus, you can connect any of the following to these cards:

- One analog LCD panel or CRT display *and* one digital LCD panel
- Two analog LCD panel or CRT displays (when the DVI-ItoVGA adapter is used)
- One analog LCD panel or CRT display *and* one TV
- One digital LCD panel *and* one TV

If the card has two DVI-I ports, in addition to using any of the preceding options, you can use two digital LCD panels.

The major video chipsets that support multiple CRT and LCD displays are listed in [Table 13.20](#).

Table 13.20. Major Multiple-Head Video Chipsets and Cards

Brand	Chipset	Bus Type(s) Supported	Number of Monitors Supported

^[1] ATI sells video cards using these chipsets under the ATI brand and also supplies chipsets to third-party vendors

[7] *Some video cards based on this chipset might not support multiple monitors All-in-One; includes TV tuner and other AV features*

[2] *Matrox is the only vendor using its chipsets; this table lists Matrox card models*

[3] *Features a separate accelerator chip for each display, enabling the independent selection of the refresh rate and the resolution under Windows 2000*

[4] *Features a separate RAMDAC chip for each display, enabling the independent selection of the refresh rate and the resolution under Windows 2000*

[6] *Upgradeable to three-monitor support*

[5] *NVIDIA does not manufacture video cards; it sells chipsets only*

As [Table 13.20](#) notes, some video cards that use a chipset capable of multiple-monitor support might not provide the additional DVI or VGA connector necessary to enable that support. Be sure to check the specifications for a particular graphics card to ensure that it supports the display combinations you need. [Table 13.20](#) does not include video chipsets that support TV-out or video in-video out (VIVO) but do not support a second CRT or LCD display.

Caution

Some vendors whose cards provide a single VGA or DVI-I port (DVI-I ports can be converted to VGA with an adapter) and a TV-out port refer to such cards as "supporting multiple monitors." [Table 13.20](#) lists only chipsets or cards that support two or more CRT or LCD displays.

Adding Multiple-Monitor Support to Laptops and Desktops with Integrated Graphics

Matrox's DualHead2Go external multiple-display device enables you to split the existing single VGA signal coming from compatible laptops or desktops with integrated graphics into two separate displays that can host their own applications, just as if your system had a dual-head-compatible graphics card installed.

The DualHead2Go device and driver software transforms the video signal coming from your computer's integrated video into an ultra wide-screen signal by using Extended Display Identification Data (EDID) and splits it into two parts that can be transmitted to different screens. Each display connected to the DualHead2Go device can display a separate program, or you can stretch a single program across both displays. See [Figure 13.15](#) for examples.

Figure 13.15. Using the Matrox DualHead2Go device to host separate applications (top) or to stretch a single application across two windows (bottom). Photos courtesy Matrox Graphics.

To determine whether your system is compatible with DualHead2Go, download and run the Matrox DualHead2Go System Compatibility Tool from <http://www.matrox.com/graphics/offhome/dh2go/try.cfm>. See the compatibility list at <http://www.matrox.com/graphics/offhome/support/dh2go/compatibility.cfm>.

3D Graphics Accelerators

Since the late 1990s, 3D acceleration once limited to exotic add-on cards designed for hardcore game players has become commonplace in the PC world. Although mainstream business users are not likely to encounter 3D imaging until Windows Vista (previously code-named Longhorn) is released in 2006, full-motion 3D graphics are used in sports, first-person shooters, team combat, driving, and many other types of PC gaming. Because even low-cost integrated chipsets offer some 3D support and 3D video cards are now in their ninth generation of development, virtually any user of a recent-model computer has the ability to enjoy 3D lighting, perspective, texture, and shading effects in her favorite games. The latest 3D sports games provide lighting and camera angles so realistic that a casual observer could almost mistake the computer-generated game for an actual broadcast, and the latest 3D accelerator chips enable fast PCs to compete with high-performance dedicated game machines, such as Sony's PlayStation 2, Nintendo's GameCube, and Microsoft's Xbox 360, for the mind and wallet of the hard-core game player.

Note

At a minimum, Windows Vista requires graphics hardware that supports DirectX 7 3D graphics; however, for maximum functionality of its 3D AeroGlass GUI, graphics hardware that supports DirectX 9 or greater is required.

How 3D Accelerators Work

To construct an animated 3D sequence, a computer can mathematically animate the sequences between keyframes. A keyframe identifies specific points. A bouncing ball, for example, can have three keyframes: up, down, and up. Using these frames as a reference point, the computer can create all the interim images between the top and bottom. This creates the effect of a smoothly bouncing ball.

After it has created the basic sequence, the system can then refine the appearance of the images by filling them in with color. The most primitive and least effective fill method is called *flat shading*, in which a shape is simply filled with a solid color. *Gouraud shading*, a slightly more effective technique, involves the assignment of colors to specific points on a shape. The points are then joined using a smooth gradient between the colors.

A more processor-intensive, and much more effective, type of fill is called *texture mapping*. The 3D application includes patterns or textures in the form of small bitmaps that it tiles onto the shapes in the image, just as you can tile a small bitmap to form the wallpaper for your Windows desktop. The primary difference is that the 3D application can modify the appearance of each tile by applying perspective and shading to achieve 3D effects. When lighting effects that simulate fog, glare, directional shadows, and others are added, the 3D animation comes very close indeed to matching reality.

Until the late 1990s, 3D applications had to rely on support from software routines to convert these abstractions into live images. This placed a heavy burden on the system processor in the PC, which has a significant impact on the performance not only of the visual display, but also of any other applications the computer might be running. Starting in the period from 1996 to 1997, chipsets on most video adapters began to take on many of the tasks involved in rendering 3D images, greatly lessening the load on the system processor and boosting overall system performance.

There have been roughly nine generations of 3D graphics hardware on PCs, as detailed in [Table 13.21](#).

Table 13.21. Brief 3D Acceleration History

Generation	Dates	Technologies	Example Product/Chipset
1st	19961997	3D PCI card with passthrough to 2D graphics card; OpenGL and GLIDE APIs	3dfx Voodoo
2nd	19971998	2D/3D PCI card	ATI Rage, NVIDIA RIVA 128
3rd	1999	2D/3D AGP 1x/2x card	3dfx Voodoo 3, ATI Rage Pro, NVIDIA TnT2
4th	19992000	DirectX 7 API, AGP 4x	NVIDIA GeForce 256, ATI Radeon
5th	2001	DirectX 8 API, programmable vertex and pixel shaders	NVIDIA GeForce 3, NVIDIA GeForce 4 Ti
6th	20012002	DirectX 8.1 API	ATI Radeon 8500, ATI Radeon 9000
7th	20022003	DirectX 9 API, AGP 8x	ATI Radeon 9700, NVIDIA GeForce FX 5900
8th	20042005	PCI Express, DirectX 9.0c	ATI X800, NVIDIA GeForce 6800
9th	2004present	DualGPU rendering with PCI Express x8, x16	ATI X1K, NVIDIA GeForce 7800; ATI CrossFire, NVIDIA nForce SLI motherboard chipsets and compatible cards

With virtually every recent graphics card on the market featuring DirectX 8.x or greater capabilities, you don't need to spend a fortune to achieve a reasonable level of 3D graphics. Many cards in the \$75\$200 range use lower-performance variants of current high-end GPUs, or they might use the previous year's leading GPU. These cards typically provide more-than-adequate performance for 2D business applications. Most current 3D accelerators also support dual-display and TV-out capabilities, enabling you to work and play at the same time.

However, keep in mind that the more you spend on a 3D accelerator card, the greater the onboard memory and faster the accelerator chip you can enjoy. Current high-end video cards featuring NVIDIA or ATI's top graphics chips, 256MB512MB of video memory, and PCI Express x16 interfaces sell for \$300\$500 each. These cards are aimed squarely at hardcore gamers for whom money is no object, and some support dual-card technologies such as NVIDIA's SLI or ATI's CrossFire, which split rendering chores across the GPUs in both video cards for faster game display than with a single card.

Mid-range cards costing \$200\$300 are often based on GPUs that use designs similar to the high-end products but might have slower memory and core clock speeds or a smaller number of rendering pipelines. These cards provide a good middle ground for users who play games fairly often but can't cost-justify high-end cards. Most of these cards are available in either PCI Express x16 or the older AGP 8x form factor.

Before purchasing a 3D accelerator adapter, you should familiarize yourself with some of the terms and concepts involved in the 3D image generation process.

The basic function of 3D software is to convert image abstractions into the fully realized images that are then displayed on the monitor. The image abstractions typically consist of the following elements:

- *Vertices*. Locations of objects in three-dimensional space, described in terms of their x, y, and z

coordinates on three axes representing height, width, and depth.

- *Primitives*. The simple geometric objects the application uses to create more complex constructions, described in terms of the relative locations of their vertices. This serves not only to specify the location of the object in the 2D image, but also to provide perspective because the three axes can define any location in three-dimensional space.
- *Textures*. Two-dimensional bitmap images or surfaces designed to be mapped onto primitives. The software enhances the 3D effect by modifying the appearance of the textures, depending on the location and attitude of the primitive. This process is called *perspective correction*. Some applications use another process, called *MIP mapping*, which uses different versions of the same texture that contain varying amounts of detail, depending on how close the object is to the viewer in the three-dimensional space. Another technique, called *depth cueing*, reduces the color and intensity of an object's fill as the object moves farther away from the viewer.

Using these elements, the abstract image descriptions must then be rendered, meaning they are converted to visible form. Rendering depends on two standardized functions that convert the abstractions into the completed image that is displayed onscreen. The standard functions performed in rendering are

- *Geometry*. The sizing, orienting, and moving of primitives in space and the calculation of the effects produced by the virtual light sources that illuminate the image
- *Rasterization*. The converting of primitives into pixels on the video display by filling the shapes with properly illuminated shading, textures, or a combination of the two

A modern video adapter that includes a chipset capable of 3D video acceleration has special built-in hardware that can perform the rasterization process much more quickly than if it were done by software (using the system processor) alone. Most chipsets with 3D acceleration perform the following rasterization functions right on the adapter:

- *Scan conversion*. The determination of which onscreen pixels fall into the space delineated by each primitive
- *Shading*. The process of filling pixels with smoothly flowing color using the flat or Gouraud shading technique
- *Texture mapping*. The process of filling pixels with images derived from a 2D sample picture or surface image
- *Visible surface determination*. The identification of which pixels in a scene are obscured by other objects closer to the viewer in three-dimensional space
- *Animation*. The process of switching rapidly and cleanly to successive frames of motion sequences
- *Antialiasing*. The process of adjusting color boundaries to smooth edges on rendered objects

Typical 3D Techniques

Typical 3D techniques include

- *Fogging*. Fogging simulates haze or fog in the background of a game screen and helps conceal the sudden appearance of newly rendered objects (buildings, enemies, and so on).
- *Gouraud shading*. Interpolates colors to make circles and spheres look more rounded and smooth.
- *Alpha blending*. One of the first 3D techniques, alpha blending creates translucent objects onscreen, making it a perfect choice for rendering explosions, smoke, water, and glass. Alpha blending also can be used to simulate textures, but it is less realistic than environment-based bump mapping.
- *Stencil buffering*. Stencil buffering is a technique useful for games such as flight simulators in which a static graphic elementsuch as a cockpit windshield frame, which is known as a heads-up display (HUD) and used by real-life fighter pilotsis placed in front of dynamically changing graphics (such as scenery, other aircraft, sky detail, and so on). In this example, the area of the screen occupied by the cockpit windshield frame is not re-rendered. Only the area seen through the "glass" is re-rendered, saving time and improving frame rates for animation.
- *Z-buffering*. The Z-buffer portion of video memory holds depth information about the pixels in a scene. As the scene is rendered, the Z-values (depth information) for new pixels are compared to the values stored

in the Z-buffer to determine which pixels are in "front" of others and should be rendered. Pixels that are "behind" other pixels are not rendered. This method increases speed and can be used along with stencil buffering to create volumetric shadows and other complex 3D objects. Z-buffering was originally developed for computer aided drafting (CAD) applications.

- *Environment-based bump mapping.* Environment-based bump mapping (standard starting in DirectX 6) introduces special lighting and texturing effects to simulate the rough texture of rippling water, bricks, and other complex surfaces. It combines three separate texture maps (for colors; for height and depth; and for environment, including lighting, fog, and cloud effects).

This creates enhanced realism for scenery in games and can also be used to enhance terrain and planetary mapping, architecture, and landscape-design applications. This represents a significant step beyond alpha blending.

- *Displacement mapping.* Special grayscale maps called displacement maps have long been used for producing accurate maps of the globe. Microsoft DirectX 9 supports the use of grayscale hardware displacement maps as a source for accurate 3D rendering. GPUs that fully support DirectX 9 in hardware support displacement mapping.

Advanced 3D Filtering and Rendering

To improve the quality of texture maps, several filtering techniques have been developed, including MIP mapping, bilinear filtering, trilinear filtering, and anisotropic filtering. These techniques and several other advanced techniques found in recent 3D GPUs are explained here:

- *Bilinear filtering.* Improves the image quality of small textures placed on large polygons. The stretching of the texture that takes place can create blockiness, but bilinear filtering applies a blur to conceal this visual defect.
- *MIP mapping.* Improves the image quality of polygons that appear to recede into the distance by mixing low-res and high-res versions of the same texture; a form of antialiasing.
- *Trilinear filtering.* Combines bilinear filtering and MIP mapping, calculating the most realistic colors necessary for the pixels in each polygon by comparing the values in two MIP maps. This method is superior to either MIP mapping or bilinear filtering alone.

Note

Bilinear and trilinear filtering work well for surfaces viewed straight-on but might not work so well for oblique angles (such as a wall receding into the distance).

- *Anisotropic filtering.* Some video card makers use another method, called anisotropic filtering, for more realistically rendering oblique-angle surfaces containing text. This technique is used when a texture is mapped to a surface that changes in two of three spatial domains, such as text found on a wall down a roadway (for example, advertising banners at a raceway). The extra calculations used take time, and for that reason, it can be disabled. To balance display quality and performance, you can also adjust the sampling size: Increase the sampling size to improve display quality, or reduce it to improve performance.
- *T-buffer.* This technology eliminates aliasing (errors in onscreen images due to an undersampled original) in computer graphics, such as the "jaggies" seen in onscreen diagonal lines; motion stuttering; and inaccurate rendition of shadows, reflections, and object blur. The T-buffer replaces the normal frame buffer with a buffer that accumulates multiple renderings before displaying the image. Unlike some other 3D techniques, T-buffer technology doesn't require rewriting or optimization of 3D software to use this enhancement. The goal of T-buffer technology is to provide a movie-like realism to 3D-rendered animations. The downside of enabling antialiasing using a card with T-buffer support is that it can dramatically impact the performance of an application. This technique originally was developed by now-defunct 3dfx. However, this technology is incorporated into Microsoft DirectX 8.0 and above.
- *Integrated transform and lighting (T&L).* The 3D display process includes transforming an object from one

frame to the next and handling the lighting changes that result from those transformations. T&L is a standard feature of DirectX starting with version 7. The NVIDIA GeForce 256 and original ATI Radeon were the first GPUs to integrate the T&L engines into the accelerator chip, a now-standard feature.

- *Full-screen antialiasing.* This technology reduces the jaggies visible at any resolution by adjusting color boundaries to provide gradual, rather than abrupt, color changes. Whereas early 3D products used antialiasing for certain objects only, recent accelerators from NVIDIA and ATI use various types of highly optimized FSAA methods that allow high visual quality at high frame rates.
- *Vertex skinning.* Also referred to as vertex blending, this technique blends the connection between two angles, such as the joints in an animated character's arms or legs.
- *Keyframe interpolation.* Also referred to as vertex morphing, this technique animates the transitions between two facial expressions, allowing realistic expressions when skeletal animation can't be used or isn't practical. See the ATI website for details.
- *Programmable vertex and pixel shading.* Programmable vertex and pixel shading became a standard part of DirectX starting with version 8.0. However, NVIDIA introduced this technique with the GeForce3's nfiniteFX technology, enabling software developers to customize effects such as vertex morphing and pixel shading (an enhanced form of bump mapping for irregular surfaces that enables per-pixel lighting effects), rather than applying a narrow range of predefined effects. The NVIDIA GeForce4 Ti's nfiniteFXII pixel shader is DirectX 8 compatible and supports up to four textures, whereas its dual vertex shaders provide high-speed rendering up to 50% faster than the GeForce3. The ATI Radeon 8500 and 9000's version, SmartShader, is supported by DirectX 8.1. DirectX 8.1 supports more complex programs than nfiniteFX and provides comparable quality to nfiniteFXII. ATI 9700, 9800, and 9500 support DirectX 9's floating-point pixel shaders and more complex vertex shader. NVIDIA GeForce FX cards also support DirectX 9 pixel and vertex shaders, but they add more features. NVIDIA's 6xxx and 7xxx series and ATI's X1K (X1xxx) series support DirectX 9.0c Shader Model 3.0.
- *Floating-point calculations.* Microsoft DirectX 9 supports floating-point data for more vivid and accurate color and polygon rendition. ATI uses standard DirectX 9 floating-point data; NVIDIA's GeForce FX uses additional-precision data; and NVIDIA's 6xxx series and 7xxx series further increase precision beyond standard DirectX 9 requirements.

[Table 13.22](#) shows when various 3D rendering features were added to DirectX versions from 6.0 to 9.0c.

Table 13.22. 3D Rendering in DirectX 6.09.0

Feature	DirectX 6.0	DirectX 7.0	DirectX 8.x	DirectX 9.0
3D sky effects	No	Yes	Yes	Yes
Smoke and fog effects (volumetric effects)	No	Limited	Yes	Yes
Dynamic refraction	No	No	Limited	Yes
Transform and lighting methods	Fixed function in software	Fixed function in hardware	Vertex Shader 1.1; Pixel Shader 1.x	Vertex Shader 2.0, 3.0 (9.0c); Pixel Shader 2.0, 3.0 (9.0c)
Bump mapping	No	No	Yes	Yes
Texture resolutions	128x128,256x256	256x256	512x512	512x512
Displacement map resolutions	Low	Medium	Medium to high with bump mapping	High with bump mapping

Appearance of water	Poor	Fair	Good	Excellent
---------------------	------	------	------	-----------

Single- Versus Multiple-Pass Rendering

Various video card makers handle application of these advanced rendering techniques differently. The current trend is toward applying the filters and basic rendering in a single pass rather than in multiple passes. Video cards with single-pass rendering and filtering typically provide higher frame-rate performance in 3D-animated applications and avoid the problems of visible artifacts caused by errors in multiple floating-point calculations during the rendering process.

Hardware Acceleration Versus Software Acceleration

Compared to software-only rendering, hardware-accelerated rendering provides faster animation. Although most software rendering would create more accurate and better-looking images, software rendering is too slow. Using special drivers, these 3D adapters can take over the intensive calculations needed to render a 3D image that software running on the system processor formerly performed. This is particularly useful if you are creating your own 3D images and animation, but it is also a great enhancement to the many modern games that rely extensively on 3D effects. Note that motherboard-integrated video solutions, such as those listed in [Tables 13.9](#) and [13.10](#), typically have significantly lower 3D performance than even low-end GPUs because they use the CPU for more of the 3D rendering than 3D video adapter chipsets do.

To achieve greater performance, many of the latest 3D accelerators run their accelerator chips at very high speeds, and some even allow overclocking of the default RAMDAC frequencies. Just as CPUs at high speeds produce a lot of heat, so do high-speed video accelerators. Both the chipset and the memory are heat sources, so most mid-range and high-end 3D accelerator cards feature a fan to cool the chipset. Also, most current high-end 3D accelerators use finned passive heatsinks to cool the memory chips and make overclocking the video card easier (refer to [Figure 13.14](#)).

Software Optimization

It's important to realize that the presence of an advanced 3D-rendering feature on any given video card is meaningless unless game and application software designers optimize their software to take advantage of the feature. Although various 3D standards exist (OpenGL and DirectX), video card makers provide drivers that make their games play with the leading standards. Because some cards do play better with certain games, you should read the reviews in publications such as *Maximum PC* to see how your favorite graphics card performs with them. Typically, it can take several months or longer after a new version of DirectX or OpenGL is introduced before 3D games take full advantage of the 3D rendering features provided by the new API.

Some video cards allow you to perform additional optimization by adjusting settings for OpenGL, Direct 3D, RAMDAC, and bus clock speeds, as well as other options. Note that the bare-bones 3D graphics card drivers provided as part of Microsoft Windows usually don't provide these dialog boxes. Be sure to use the drivers provided with the graphics card or download updated versions from the graphics card vendor's website. Although you can sometimes use generic drivers provided by the GPU vendor, you should use drivers that have been specifically developed for your card to ensure that your card's particular features are fully supported.

Note

If you want to enjoy the features of your newest 3D card immediately, be sure to purchase the individual retail-packaged version of the card from a hardware vendor. These packages typically come with a sampling of games (full and demo versions) designed or compiled to take advantage of the card with which they're sold. The lower-cost OEM or "white box" versions of video cards are sold

without bundled software, come only with driver software, and might differ in other ways from the retail advertised product. Some even use modified drivers, use slower memory or RAMDAC components, or lack special TV-out or other features. Some 3D card makers use different names for their OEM versions to minimize confusion, but others don't. Also, some card makers sell their cards in bulk packs, which are intended for upgrading a large organization with its own support staff. These cards might lack individual documentation or driver CDs and also might lack some of the advanced hardware features found on individual retail-pack video cards.

Application Programming Interfaces

Application programming interfaces (APIs) provide hardware and software vendors a means to create drivers and programs that can work quickly and reliably across a wide variety of platforms. When APIs exist, drivers can be written to interface with the API rather than directly with the operating system and its underlying hardware.

Currently, the leading game APIs include SGI's OpenGL and Microsoft's Direct3D (part of DirectX). OpenGL and Direct3D are available for virtually all leading graphics cards. At one time, a third popular game API was Glide, an enhanced version of OpenGL that is restricted to graphics cards that use 3Dfx chipsets, which are no longer on the market.

OpenGL

The latest version of OpenGL is version 2.0, released on September 7, 2004. The OpenGL Shading Language, an optional feature of the previous version (OpenGL 1.5), is now a core feature of OpenGL 2.0. OpenGL 2.0 also supports programmable vertex and fragment shaders, multiple render targets, improved textures, and other enhancements.

Although OpenGL is a popular gaming API, it is also widely used in 3D rendering for specialized business applications, including mapping, life sciences, and other fields. To learn more about OpenGL, see the OpenGL website at www.opengl.org. OpenGL support is provided by the video card or chipset vendor through driver updates.

Microsoft DirectX

Direct3D is part of Microsoft's comprehensive multimedia API, DirectX. Although DirectX 8.0, 8.1, and 9.0 all provide support for higher-order surfaces (converting 3D surfaces into curves), vertex shaders, and pixel shaders, significant differences exist between DirectX 8.0/8.1 and 9.0 in how these operations are performed.

The difference between DirectX 8.0 (used by NVIDIA) and DirectX 8.1 (used by ATI and Matrox) involves the pixel shader portion of the 3D rendering engine. DirectX 8.1's pixel shader can handle more texture maps (6 versus 4) and more texture instructions (8 versus 4) than DirectX 8.0. DirectX 8.1 also handles integer data with 48-bit precision, versus DirectX 9.0's 32-bit precision. However, both pale in comparison to DirectX 9.0's pixel shader, which handles up to 16 texture maps, up to 32 texture instructions, and up to 64 color instructions and uses floating-point data at 128-bit precision.

To create higher-order surfaces, DirectX 9 supports continuous *tessellation* (the process of converting a surface into small triangles using floating-point math for greater precision) and displacement mapping in addition to the n-patches method used by DirectX 8.0 and 8.1.

DirectX 9.0's vertex shader is capable of handling many more complex commands than the DirectX 8.x shader: 1,024 instructions versus 128 and up to 256 constants versus 96. DirectX 9.0 also supports flow control.

The latest version of DirectX is version 9.0c. DirectX 9.0c supports improved pixel and vertex shading (65,535 instructions with 32-bit floating-point precision), dynamic branching, and vertex texture lookups through its support for Shader Model 3.0. (DirectX 9.0 supports only Shader Model 2.0.) Currently, NVIDIA 6xxx and 7xxx GPUs and ATI's X1K series support DirectX 9.0c (and thus Shader Model 3.0), whereas ATI's first-generation PCI Express cards (X850X300) use Shader Model 2.0.

Note

DirectX provides backward compatibility to support games and other programs written for earlier DirectX versions. Thus, installing the latest version of DirectX enables you to play games that require it while maintaining compatibility with older games.

For more information about DirectX or to download the latest version, see Microsoft's DirectX website at www.microsoft.com/windows/directx.

Note

DirectX 9.x is for Windows 98 and later versions (98SE, Me, 2000, and XP) only. However, Microsoft still provides DirectX 8.0a for Windows 95 users.

Dual-GPU Scene Rendering

In [Table 13.21](#), I placed the development of dual PCI Express graphics card solutions as the ninth generation of 3D acceleration. The ability to connect two cards together to render a single display more quickly isn't exactly new: The long-defunct 3dfx Voodoo 2 offered an option called *scan-line interfacing (SLI)*, which pairs two Voodoo 2 cards together on the PCI bus with each card writing half the screen in alternating lines. With 3dfx's version of SLI, card number one wrote the odd-numbered screen lines (one, three, five, and so on), while card number two wrote the even-numbered screen lines (two, four, six, and so on). While popular and effective, use of SLI with Voodoo 2 was an expensive proposition that only a handful of deep-pocketed gamers took advantage of.

A few companies also experimented with using multiple GPUs on a single card to gain a similar performance advantage, but these cards never became popular. However, the idea of doubling graphics performance via multiple video cards has proven too good to abandon entirely, even after 3dfx went out of business.

NVIDIA SLI

When NVIDIA bought what was left of 3dfx, it inherited the SLI trademark and, in mid-2004, reintroduced the concept of using two cards to render a screen under the same acronym. However, NVIDIA's version of SLI has a different meaning and much more intelligence behind it.

NVIDIA uses the term *SLI* to refer to scalable link interface. The *scaling* refers to load-balancing, which adjusts how much of the work each card performs to render a particular scene, depending on how complex the scene is. To enable SLI, the following components are needed:

- *A PCI Express motherboard with an SLI-compatible chipset and two PCI Express video slots designed for SLI operation.* Motherboards based on the NVIDIA nForce 4 SLI, SLI x16, and nForce Professional chipsets are the first to support SLI operation. Versions are available for Pentium 4, Pentium D, and Athlon 64

processors.

- Two NVIDIA-based video cards in the GeForce 7800, 6800, or 6600 series with SLI support. A special bridge device known as a *multipurpose I/O (MIO)* is used to connect the cards to each other. The MIO is supplied with SLI-compatible motherboards.

Note

Originally, you needed to use two identical cards for NVIDIA SLI. With the introduction of NVIDIA ForceWare v81.85 or higher driver versions, this is no longer necessary. Just as with the ATI CrossFire multi-GPU solution, the cards need to be from the same GPU family (two 7800, two 6800, or two 6600 cards), but they don't need to be from the same manufacturer. You can obtain updated drivers from your video card maker or from the NVIDIA website (www.nvidia.com).

For best results, SLI should be used with games that have been optimized for SLI. More than 60 games feature in-box SLI support, but you can download customized game profiles from NVIDIA's official SLI website: www.slizone.com. You can enable or disable SLI rendering and load balancing through the NVIDIA configuration software installed during the cards' installation process.

[Figure 13.16](#) illustrates a typical SLI hardware configuration. Note the MIO device connecting the cards to each other.

Figure 13.16. How NVIDIA SLI looks in a typical installation.

ATI CrossFire

ATI's CrossFire multi-GPU technology uses three methods to speed up display performance: alternate frame rendering; *supertiling*, which divides the scene into alternating sections and uses each card to render parts of the scene; and load-balancing scissor operation (similar to SLI's load-balancing). The ATI Catalyst driver uses alternate frame rendering for best performance, but automatically switches to one of the other modes for games that don't work with alternate frame rendering.

To achieve better image quality than with a single card, CrossFire offers various SuperAA (antialiasing) modes, which blend the results of antialiasing by each card. CrossFire also improves anisotropic filtering by blending the filtering performed by each card.

To use CrossFire, you need the following components:

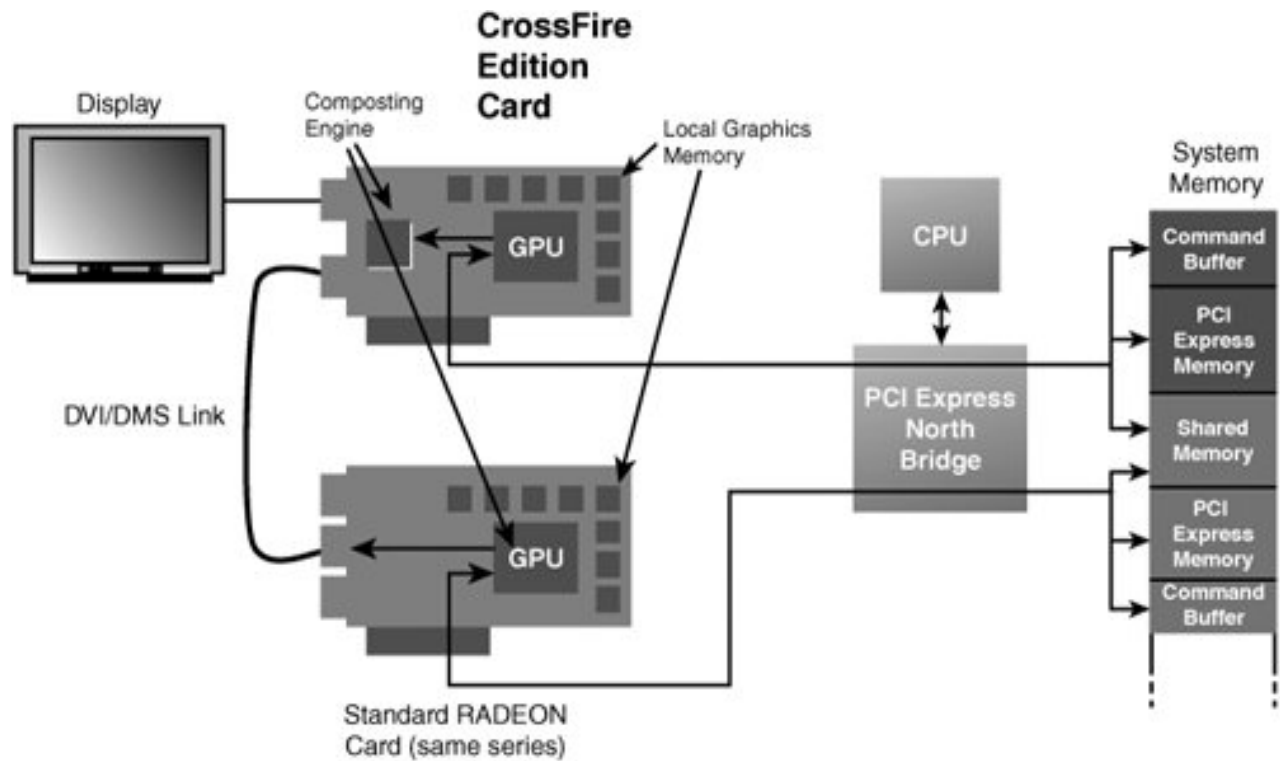

- A PCI Express motherboard with a CrossFire-compatible chipset and two PCI Express video slots designed for CrossFire operation. Motherboards based on the ATI XPress 200 chipsets are the first to support CrossFire operation.
- A supported combination of ATI CrossFire-supported cards.

For CrossFire support for the X800, X850, and X1800 series, ATI has developed special CrossFire Edition cards that contain the composting engine (an Xilinx XC3S400 chip) and use a proprietary DMS-59 port for interconnecting the cards. One of these cards can be paired with a standard Radeon card from the same series. For example, you can pair an X800 CrossFire Edition with an existing X800XL. To connect these cards, a special external patch cable is used to connect the cards via the CrossFire Edition's DMS port and the DVI port on the standard card. The slower X1300 and X1600 series no longer use a special CrossFire Edition card as a master. You can pair any two X1300 or any two X1600 cards together on a CrossFire motherboard and the PCI Express bus is used to transfer information between the cards. The X1800 solution supports higher refresh rates at 1600x1200 than the X800 or X850.

CrossFire can be disabled to permit multimonitor operation. [Figure 13.17](#) illustrates how the X800/X850/X1800 cards implement CrossFire.

Figure 13.17. How data flows in a typical ATI CrossFire implementation using X800, X850, or X1800 cards.

[\[View full size image\]](#)

For more information about CrossFire, see the ATI website at www.ati.com.

3D Chipsets

Virtually every mainstream video adapter in current production features a 3D accelerationcompatible chipset. With several generations of 3D adapters on the market from the major vendors, keeping track of the latest products can be difficult. [Table 13.23](#) lists the major 3D chipset manufacturers, the various chipsets they make, and the major features of each chipset.

Table 13.23. 3D Video Chipset Manufacturers and Products

Manufacturer: ATI								
GPU (Codename)	DirectX Version	Hard- ware T&L	Rendering Pipelines	Programmable Vertex Shader Pipelines	Memory Bus	Mfr. Process	Interface	Notes
Radeon (R100/Rage 6C)	7	Yes	2	N/A	128-bit	.18 micron	AGP 4x, PCI

SiS315	7	Yes	2	N/A	64-bit, 128-bit	.15 micron	AGP 4x	
Xabre 80	8.1	Yes	4	2	64-bit, 128-bit	.15 micron	AGP 4x	
Xabre 200, 400	8.1	Yes	4	2	128-bit	.15 micron	AGP 8x	Dual-display (400);
Xabre 600	8.1	Yes	4	2	128-bit	.13 micron	AGP 8x	Dual-display; faster version of Xabre 400

Manufacturer: XGI

GPU/Card (Codename)	DirectX Version	Hard- ware T&L	Rendering Pipelines	Programmable Vertex Shader Pipelines	Memory Bus	Mfr. Process	Interface	Notes
Volari V8, V8 Ultra (V8 Duo: 2-chip version)	9.0	Yes	8 (16)	2 (4)	128-bit (256-bit)	.13 micron	AGP 8x	Dual-display
Volari V5, V5 Ultra (V5 Duo: 2-chip version)	9.0	Yes	4 (8)	2 (4)	128-bit (256-bit)	.13 micron	AGP 8x	Dual-display

Manufacturer: AGI

GPU/Card (Codename)	DirectX Version	Hard- ware T&L	Rendering Pipelines	Programmable Vertex Shader Pipelines	Memory Bus	Mfr. Process	Interface	Notes
------------------------	--------------------	----------------------	------------------------	---	---------------	-----------------	-----------	-------

Volari V3	8.1	Yes	2	1	64-bit; 128-bit)	.13 micron	AGP 8x	Up to four displays; based on Trident XP4
Volari V3XT	9	Yes	2	1	64-bit	.13 micron	AGP 8x or PCI	
Volari 8300	9	Yes	4	4	64-bit	.13 micron	PCI Express x16	32MB onboard; uses up to 96MB of system RAM

AIW: Indicates ATI GPUs also used in the ATI All-in-Wonder series of TV-tuner/capture graphics cards.

CrossFire Edition: Card version that can be paired with a standard Radeon in the same series on a CrossFire-enabled motherboard.

PCIe: PCI Express x16.

PCinema: Indicates NVIDIA GPUs also used in Personal Cinema TV-tuner/capture graphics cards.

XGI: Spinoff of SiS's graphics chip division; later acquired Trident's graphics subsidiary.

SiS no longer manufactures 3D graphics chips; it spun off its multimedia division as XGI (see the next section for XGI products).

Professional graphics workstation cards and chipsets from vendors such as 3DLabs (www.3dlabs.com), ATI, and NVIDIA are not listed in [Table 13.23](#) because these cards are not found in standard desktop computers. See the vendors' websites for details about these products.

Note

See [Chapter 15](#) in both *Upgrading and Repairing PCs, 12th Edition* and *13th Edition* on this book's disc for more information about older chipsets from current manufacturers and for chipsets from manufacturers who no longer produce 3D graphics hardware.

Note

[Table 13.23](#) is designed to be a reference to recent and current GPUs (and graphics cards) from current vendors. Only GPUs that meet fourth-generation (DirectX 7) or newer standards are included. Refer to [Table 13.21](#) for the criteria I use to describe each 3D generation. Because most graphics card vendors now use the GPU name as part of the product name, [Table 13.23](#) does not include product examples. See *Upgrading and Repairing PCs, 15th Anniversary Edition*, available in electronic form on the disc packaged with this book, for a table matching older graphics card GPUs and product names.

Be sure to use this information in conjunction with application-specific and game-specific tests to help you choose the best card/chipset solution for your needs. Consult the chipset vendors' websites for the latest information about third-party video card sources using a specific chipset.

Most chipsets in [Table 13.23](#) feature some level of dual-display support, typically offering VGA, DVI-I, and TV-out. See the details for a particular video card to determine which features it implements as well as its memory size and other particulars.

[← PREV](#)[NEXT →](#)

Upgrading or Replacing Your Video Card

With today's video cards offering sophisticated 3D graphics supporting DirectX 8.x and 9.x, multiple-monitor support at most price points, and massive amounts of display memory (up to 512MB!), it makes little sense to add most upgrades to an existing video card. The component-level upgrades that can be added generally include

- TV tuners, permitting you to watch cable or broadcast TV on your monitor
- Video capture devices, allowing you to capture still or moving video to a file

In many cases, a single device provides both features. However, if you need better 3D performance or features, more memory, or support for DVI digital displays, you need to replace your video card.

TV Tuner and Video Capture Upgrades

With a few notable exceptions, such as ATI's Radeon All-in-Wonder and NVIDIA's Personal Cinema series or cards with VIVO (video-in/video-out ports), most video cards don't have TV tuner or video capture upgrade features built in. New cards with these features tend to be either in the middle to high range of their manufacturers' price structures or less expensive but of poor quality.

These features are exciting if you are already into video editing, want to add video to your website, or are trying to create CD- or DVD-based archives of your home video. If you have an up-to-date video card with acceptable 2D and 3D performance and at least 128MB of video RAM, compare the price of the addons to the price of a new card with these features. You'll probably find the add-ons to be less expensive. If your card has less than 128MB of video RAM and you play 3D games, I recommend replacing it with a new card with these features. Look at sample video captures before making your decision because all video capture solutions require image compression with at least some loss of quality. If you have a digital camcorder with IEEE 1394 (also called FireWire or i.LINK) ports, you should purchase an IEEE 1394 interface board to use high-quality pure digital video that needs no conversion.

Note

Although ATI's All-in-Wonder Radeon 8500 DV includes an IEEE 1394a (FireWire 400) port, more recent All-in-Wonder boards don't include this port. However, a wide variety of multifunction PCI cards include IEEE 1394a ports, including high-end sound cards from Hercules and Creative Labs and combination Hi-Speed USB (USB 2.0)/IEEE 1394a cards from many vendors. Many recent systems also include a 1394a or 1394b port.

The USB port can be used to connect TV tuner and video-capture options compatible with any manufacturer's video card from vendors such as Dazzle, Hauppauge, and others. Because the wide variety of TV and computer hardware on the market can cause compatibility problems with USB TV/capture devices, be sure to check review sites such as <http://reviews.cnet.com> and <http://www.epinions.com>. For best image capture quality, look for products designed for Hi-Speed USB (USB 2.0) and connect them to a

If HDTV is in your future, look for products compatible with HDTV, such as an HDTV tuner (some plug in to an empty PCI slot, and others plug in to a USB 2.0 port). HDTV tuners enable you to watch HDTV broadcasts on any monitor connected to your PC, including large-screen monitors and projectors. Some of the major vendors of HDTV cards include ATI Technologies, Hauppauge Computer Works, and Sasem Co, Ltd.

Warranty and Support

Because a video card can go through several driver changes during its effective lifetime (about three years or two operating-system revisions), buying a video card from a major manufacturer usually assures you of better support during the card's lifetime. If you buy a card that uses widely available chipsets (such as NVIDIA's or ATI's), you might be able to try a different vendor's version of drivers or use the chipset vendor's "generic" drivers if you don't get satisfactory support from your card vendor.

Keep in mind that using generic drivers (chipset level) or a different brand of drivers can cause problems if your original card's design was tweaked from the chipset maker's reference design. Look at the vendor's technical support forums or third-party discussions on newsgroups, computer information websites such as ZDNet, or magazine websites to get a feel for the stability, reliability, and usefulness of a vendor's support and driver services. These sources generally also provide alternatives in case of difficulties with a specific brand or chipset. If you use Windows Me, Windows 2000, or Windows XP, make sure you use WHQL-certified drivers for best results. These drivers have been passed by Microsoft's Windows Hardware Quality Labs and might be available through Windows Update or from the vendor's own website.

Note

With the rise in popularity of Linux, many graphics card and GPU vendors now provide downloadable Linux drivers. Be sure to check compatibility carefully because some vendors customize drivers for different Linux distributions or might provide drivers that work with only certain Linux kernels or XFree86 drivers.

Comparing Video Cards with the Same Chipset

Many manufacturers create a line of video cards with the same chipset to sell at different pricing points. Why not save some dollars and get the cheapest model? Why not say "price is no object" and get the most expensive one? When you're faced with various cards in the "chipsetX" family, look for differences such as those shown in [Table 13.24](#).

Table 13.24. Comparing Video Cards with the Same Chipset

Feature	Effect on You
1. Personalized Recommendations	Helps you discover new products and services tailored to your interests.
2. Targeted Advertising	Shows you relevant ads, reducing clutter and increasing the chances of finding what you need.
3. Streamlined Navigation	Makes it easier to find what you're looking for, saving time and frustration.
4. Enhanced Security	Protects your personal information and transactions, giving you peace of mind.
5. Improved Customer Support	Provides timely assistance and resolves issues, ensuring a smooth shopping experience.

RAMDAC speed	Most current high-end 3D GPUs integrate 400MHz or faster RAMDACs to provide flicker-free resolutions beyond 1280x1024. However, less-expensive cards and older designs often incorporate a slower RAMDAC, which reduces maximum and flicker-free resolutions. If you use a 17" or larger monitor, this could be an eye-straining problem.
Amount of RAM	Although AGP video cards can use AGP memory (a section of main memory borrowed for texturing), performing as much work as possible on the card's own memory is still faster. PCI and PCI Express cards must perform all functions within their own memory. Less expensive cards in a chipset family often have lower amounts of memory onboard, and graphics cards haven't featured expandable memory for several years. Buy a card with enough memory for your games or applications today and tomorrow; at least 64MB or more for business and 128MB or more for gaming, 3D graphics, and video-related work. If you plan to upgrade to Windows Vista (introduced in late 2006), consider a video card with 256MB or more and DirectX 9 hardware support to enable you to use the optional Aero Glass GUI feature.
Memory type	Virtually all video cards on the market today use SDRAM or its faster variants (SGRAM, DDR SDRAM, GDDR2, or GDDR3 SDRAM). Any of these provide you with high performance in business applications, although DDR, GDDR2, or GDDR3 SDRAM is preferable when running high-resolution, high-quality 3D games faster.
Core clock speed	Many suppliers adjust the recommended speed of graphics controllers in an effort to provide users with maximum performance. Sometimes the supplier can choose to exceed the rated specification of the graphics chip. Be cautious: Current controller chips are large and can overheat. An overclocked device in an open system with great airflow might work, or it might fail in a period of months from overstress of the circuitry. If you have questions about the rated speed of a controller, check the chip supplier's website. Many reputable companies do use overclocked parts, but the best vendors supply large heatsinks or powered fans to avoid overheating. Some vendors even provide on-card temperature monitoring.
RAM speed (MHz rating)	Just as faster system RAM improves overall computer performance, faster video card RAM improves video card performance. The higher the MHz rating, the faster the memory.
TV-out	Once a rare feature, most video cards at all price points now feature TV-out, enabling you to display DVD movies or video games on a big-screen TV. Most use the S-video port, which can be adapted to composite video if your TV or VCR does not have an S-video port. Some of the latest models have hardware-based MPEG-2 compression for higher video quality in less disk space. Some of the latest video cards are now using a VIVO port to support either RCA or S-video inputs on VCRs and TVs.
Multimedia features	The ATI All-in-Wonder series provides TV-in, TV-out, and full-power graphics support in a single slot. An adapter for component video is available from ATI for interfacing with bigscreen televisions. If you prefer NVIDIA graphics, look for GeForce FX-based cards that include the Personal Cinema breakout box and software bundle. Even though All-in-Wonder versions of ATI's most recent GPUs are available, NVIDIA's Personal Cinema products are not currently available in the GeForce 6 or 7 series.

The speed of the RAMDAC is not the same as the core clock speed of a given graphics card. Even though most current GPUs incorporate the RAMDAC in the GPU, the RAMDAC and the GPU core run at different speeds.

Video Output Devices

When video technology first was introduced, it was based on television. However, a difference exists between the signals used by a television and those used by a computer. In the United States, the National Television System Committee (NTSC) established color TV standards in 1953. Some other countries, such as Japan, followed this standard. Many countries in Europe, though, developed more sophisticated standards, including Phase Alternate Line (PAL) and Sequential Couleur Avec Mémoire (SECAM). [Table 13.25](#) shows the differences among these standards.

Table 13.25. Television Versus Computer Monitors

Standard	Year Est.	Country	Lines	Rate
<i>Television</i>				
NTSC	1953 (color) 1941 (b&w)	U.S., Japan	525	60 fields/sec
PAL	1941	Europe ^[1]	625	50 fields/sec
SECAM	1962	France	625	25 fields/sec
HDTV ^[2]		Various countries	1080i 720p	25 fields/sec 60 frames/sec
<i>Computer</i>				
VGA	1987	U.S.	640x480 ^[3]	72Hz

Field = 1/2 (.5 frame)

^[1] *England, Holland, and West Germany.*

^[2] *Various analog and digital HDTV standards have been introduced around the world, starting in France in 1948 (SECAM 755i, a now-discontinued analog version); Japan's analog MUSE 1035i is the oldest system (1979present) in use. The U.S. standards (both digital) are listed above; other countries use various analog and digital standards.*

^[3] *VGA is based on more lines and uses pixels (480) versus lines; genlocking is used to lock pixels into lines and synchronize computers with TV standards.*

A video-output (or VGA-to-NTSC) adapter enables you to display computer screens on a TV set or record

them onto videotape for easy distribution. These products fall into two categories: those with genlocking (which enables the board to synchronize signals from multiple video sources or video with PC graphics) and those without. Genlocking provides the signal stability necessary to obtain adequate results when recording to tape, but it isn't necessary for using a television as a video display.

VGA-to-NTSC converters are available as internal expansion boards, external boxes that are portable enough to use with a laptop for presentations on the road, and TV-out ports on the rear of most video cards using chipsets from NVIDIA, ATI, and others. Indeed, many laptop and notebook systems these days come equipped with a built-in VGA-to-NTSC converter.

The converter does not replace your existing video adapter but instead connects to the adapter using an external cable. In addition to VGA input and output ports, a video output board has a video output interface for S-video and composite video (via an adapter).

Most VGA-to-TV converters support the standard NTSC television format and might also support the European PAL format. The resolution these devices display on a TV set or record on videotape often is limited to straight VGA at 640x480 pixels, although some TV-out ports on recent video cards can also display 800x600 resolution. The converter also might contain an antiflicker circuit to help stabilize the picture because VGA-to-TV products, as well as TV-to-VGA solutions, often suffer from a case of the jitters.

To connect your PC to an HDTV monitor, use a DVI-D cable for best picture quality, or use the VGA port if your system lacks DVI support.

Video Capture Devices

You can capture individual screen images or full-motion video for reuse in several ways, including

- 3D accelerator cards with TV-in ports
- TV tuner cards
- USB-based devices such as TV tuner/capture devices
- Webcams with video input ports

These units capture still or moving images from NTSC video sources, such as camcorders and VCRs. Although image quality is limited by the input signal, the results are still good enough for presentations and desktop publishing applications. These devices work with VGA cards set for 24-bit or 32-bit color and usually accept video input from VHS, Super VHS, and Hi-8 devices. As you might expect, however, Super VHS and Hi-8 video sources give better results, as do configurations using more than 256 colors. For the best results, use DV camcorders equipped with IEEE 1394 (i.LINK/FireWire) connectors; these can output high-quality digital video direct to your computer without the need to perform an analog-to-digital conversion. If your computer doesn't include an IEEE 1394a or 1394b port, you must install an IEEE 1394 add-in card if you want to capture output from a DV camcorder.

Tip

If you need to convert existing analog video tape to digital format and you also have a DV camcorder (which interfaces via the IEEE 1394 port), check the documentation for your camcorder to see whether it can be used as a passthrough device for analog video. DV camcorders that support passthrough enable you to capture analog video via the 1394 port for better image quality than if you used a USB-based capture device.

Desktop Video Boards

You can also capture NTSC (television) signals to your computer system for display or editing. In other words, you can literally watch TV in a window on your computer. When capturing video, you should think in terms of digital versus analog. The biggest convenience of an analog TV signal is efficiency; it is a compact way to transmit video information through a low-bandwidth pipeline. The disadvantage is that although you can control how the video is displayed, you can't edit it.

Actually capturing and recording video from external sources and saving the files onto your PC requires special technology. To do this, you need a device called a *video capture board* (also called a TV tuner, video digitizer, or video grabber).

Note

In this context, the technical nomenclature again becomes confusing because the term *video* here has its usual connotation; that is, it refers to the display of full-motion photography on the PC monitor. When evaluating video hardware, be sure to distinguish between devices that capture still images from a video source and those that capture full-motion video streams.

Today, video sources come in two forms:

- Analog
- Digital

Analog video can be captured from traditional sources such as broadcast or cable TV, VCRs, and camcorders using VHS or similar tape standards. This process is much more demanding of storage space and system performance than still images are. Here's why:

The typical computer screen was designed to display mainly static images. The storing and retrieving of these images requires managing huge files. Consider this: A single, full-screen color image in an uncompressed format can require as much as 2MB of disk space; a 1-second video would therefore require 45MB. Likewise, any video transmission you want to capture for use on your PC must be converted from an analog NTSC signal to a digital signal your computer can use. On top of that, the video signal must be moved inside your computer at 10 times the speed of the conventional ISA bus structure. You need not only a superior video card and monitor, but also an excellent expansion bus, such as PCI or AGP.

Considering that full-motion video can consume massive quantities of disk space, it becomes apparent that data compression is all but essential. Compression and decompression apply to both video and audio. Not only does a compressed file take up less space, it also performs better simply because less data must be processed. When you are ready to replay the video/audio, the application decompresses the file during playback. In any case, if you are going to work with video, be sure that your hard drive is large enough and fast enough to handle the huge files that can result.

Compression/decompression programs and devices are called *codecs*. Two types of codecs exist: hardware-dependent codecs and software (or hardware-independent) codecs. Hardware codecs typically perform better; however, they require additional hardware either an add-on card or a high-end video card with hardware codecs built in. Software codes do not require hardware for compression or playback, but they

typically do not deliver the same quality or compression ratio. Following are two of the major codec algorithms:

- *JPEG (Joint Photographic Experts Group)*. Originally developed for still images, JPEG can compress and decompress at rates acceptable for nearly full-motion video (30fps). JPEG still uses a series of still images, which makes editing easier. JPEG is typically lossy (meaning that a small amount of the data is lost during the compression process, slightly diminishing the quality of the image), but it can also be lossless. JPEG compression functions by eliminating redundant data for each individual image (intraframe). Compression efficiency is approximately 30:1 (20:140:1).
- *MPEG (Motion Picture Experts Group)*. MPEG by itself compresses video at approximately a 30:1 ratio, but with precompression through oversampling, the ratio can climb to 100:1 and higher, while retaining high quality. Thus, MPEG compression results in better, faster videos that require less storage space. MPEG is an interframe compressor. Because MPEG stores only incremental changes, it is not used during editing phases.

If you will be capturing or compressing video on your computer, you'll need software based on standards such as Microsoft's DirectShow (the successor to Video for Windows and ActiveMovie), Real Network's Real Producer series, or Apple's QuickTime Pro. Players for files produced with these technologies can be downloaded free from the vendors' websites.

To play or record video on your multimedia PC (MPC), you need some extra hardware and software:

- Video system software, such as Apple's QuickTime for Windows or Microsoft's Windows Media Player.
- A compression/digitization video adapter that enables you to digitize and play large video files.
- An NTSC-to-VGA adapter that combines TV signals with computer video signals for output to a VCR. Video can come from a variety of sources: TV, VCR, video camera, laserdisc player, or DVD player. When you record an animation file, you can save it in a variety of file formats: AVI (Audio Video Interleave), MOV (Apple QuickTime format), or MPG (MPEG format).

Depending on the video-capture product you use, you have several choices for capturing analog video. The best option is to use component video. Component video uses three RCA-type jacks to carry the luminance (Y) and two chrominance (PR and PB) signals; this type of connector commonly is found on DVD players and high-end conventional and HDTV television sets. However, home-market video capture devices usually don't support component video. A typical professional capture device designed for component video, such as Pinnacle Systems' DC2000DV, retails for about \$2,000.

The next best choice, and one that is supported by many home-market video-capture devices, is the S-video (S-VHS) connector. This cable transmits separate signals for color (chroma) and brightness (luma). Otherwise, you must use composite video, which mixes luma and chroma. This results in a lower-quality signal, and the better your signal, the better your video quality will be.

You also can purchase devices that display only NTSC (TV) signals on your computer. The built-in digital movie editing features found in Windows XP and Windows Vista, the increasing popularity of computer/TV solutions, and broadband Internet connections make onscreen full-motion video an increasingly common part of the computing experience. Because of the growing importance of onscreen full-motion video, more and more recent CPUs have added features to enhance playback including SSE, SSE2, and SSE3 instructions in the most recent processors from AMD and Intel. Computers that use Windows XP Media Center Edition are ready out of the box to capture and digitally record video from TV for playback later, functioning as a personal video recorder (PVR). In addition, many graphics cards with TV-in, such as ATI's Radeon-based All-in-Wonder series and NVIDIA's Personal Cinema FX, also include PVR software. A remote control and onscreen program guide is often included to make TV viewing and recording even easier.

[Table 13.26](#) provides a breakdown of some common video cards and capture devices supporting key features. This table is not inclusive and is meant to serve only as a reference example.

Table 13.26. Video Capture Devices

Device Type	Example
Video card with TV tuner and PVR	ATI All-in-Wonder series, NVIDIA Personal Cinema FX
PCI TV-tuner and PVR	ATI-TV Wonder VE, HDTV Wonder
USB TV-tuner and PVR	Hauppauge WinTV-PVR-USB2
USB port video capture	Dazzle Digital Video Creator series
PCI video capture card	Broadway Pro DVD
IEEE 1394 (FireWire)	AVerMedia DVD EzMaker

[Figure 13.18](#) shows a typical video adapter incorporating TV tuner and video-in and video-out features: the ATI All-in-Wonder X800 XT. This example features an AGP 8x interface, but other All-in-Wonder cards also support PCI Express x16.

Figure 13.18. ATI's All-in-Wonder X800 XT is a mid-range video accelerator with integrated TV and FM tuners, dual-display capabilities, and video-capture/PVR features. A multihead AV output cable, AV input breakout box, and remote control are also included. *Photos courtesy of ATI Technologies.*

[\[View full size image\]](#)

Each type of device has advantages and potential disadvantages. [Table 13.27](#) provides a summary that will help you decide which solution is best for you.

Table 13.27. Multimedia Device Comparison

Device Type	Pros	Cons
Graphics card with built-in TV tuner and capture	Convenience; single-slot solution	Upgrading requires card replacement.
TV-tuner card	Allows upgrade to existing graphics cards; might be movable to newer models	Might not work with all current chipsets.

USB port attachment	Easy installation and transfer between different computers; USB 2.0-compatible devices fast enough for high-quality video	Must use USB 2.0 (Hi-Speed (USB) port for adequate
Dedicated PCI interface card	Fast frame rate for realistic video; works any graphics card	High resource requirements (IRQ and so on) on some models; requires internal installation.
IEEE 1394 (FireWire) connection to digital video	No conversion from analog to digital needed; all-digital image is very high quality without compressions artifacts (blocky areas) in video; fast throughput	Requires IEEE 1394 port, IEEE 1394 digital video source; card requires internal installation; some cards don't include capture/editing software purchased separately works with card.

Troubleshooting Video Capture Devices

[Table 13.28](#) provides some advice for troubleshooting problems with video capture devices. Note that IRQ conflicts can be an issue with both parallel port and add-on card devices and that low-bandwidth devices such as parallel port or USB devices might not be capable of supporting full-motion video capture except in a small window.

Table 13.28. Troubleshooting Video Capture Devices

Device Type	Problem	Solutions
TV tuners (built-in graphics card or add-on)	No picture.	Check cabling; set signal source correctly in software; update software.
All devices	Video capture is jerky.	Frame rate is too low. Increasing it might require capturing video in a smaller window; use fastest parallel port setting you can; use faster CPU and increase RAM to improve results.
All devices	Video playback has pauses, dropped frames.	Hard disk might be pausing for thermal recalibration; use AV-rated SCSI hard drives, UDMA EIDE drives, or SATA drives; install correct busmastering EIDE drivers for motherboard chipset and make sure UDMA mode is enabled for ATA/IDE ports to improve speed. Reinstall video playback software. Update device drivers.

USB devices	Device can't be detected or doesn't work properly.	Use Windows 98/Me/2000/XP; if you use a USB hub, be use a USB hub, be sure it's self-powered; make sure USB 2.0 port is configured to operate in Hi-Speed mode; use USB 2.0-compatible devices; update drivers.
Interface cards (all types)	Card can't be detected or doesn't work.	Check for IRQ conflicts in Windows Device Manager; move doesn't work. card to different slot if possible. Make sure additional power is provided for card if card requires it.
IEEE 1394 cards	Card can't be detected or doesn't work.	Make sure power connector is attached to card if card has 4-pin power jack. Make sure correct drivers are installed.
All devices	Capture or installation problems.	Use the newest drivers available; check manufacturers' website website for updates, FAQs, and so on. Check cables.

Adapter and Display Troubleshooting

Solving most graphics adapter and monitor problems is fairly simple, although costly, because replacing the adapter or display is the normal procedure. However, before you take this step, be sure you have exhausted all your other options. One embarrassingly obvious fix to monitor display problems that is often overlooked by many users is to adjust the controls on the monitor, such as contrast and brightness. Although most monitors today have a control panel on the front of the unit, other adjustments might be possible as well.

Some NEC monitors, for example, have a focus adjustment screw on the left side of the unit. Because the screw is deep inside the case, the only evidence of its existence is a hole in the plastic grillwork on top of it. To adjust the monitor's focus, you must stick a long-shanked screwdriver about 2" into the hole and feel around for the screw head. This type of adjustment can save you both an expensive repair bill and the humiliation of being ridiculed by the repair technician. Always examine the monitor case, documentation, and manufacturer's website or other online services for the locations of adjustment controls. Most recent CRT and LCD monitors use front-mounted controls with onscreen display (OSD).

A defective or dysfunctional adapter or display usually is replaced as a single unit rather than being repaired. Except for specialized CAD or graphics workstation-oriented adapters, virtually all of today's adapters cost more to service than to replace, and the documentation required to service the hardware properly is not always available. You usually can't get schematic diagrams, parts lists, wiring diagrams, and other documents for most adapters or monitors. Also, virtually all adapters now are constructed with surface-mount technology that requires a substantial investment in a rework station before you can remove and replace these components by hand. You can't use a \$25 pencil-type soldering iron on these boards!

Servicing monitors is a slightly different proposition. Although a display often is replaced as a whole unit, some displays—particularly 20" or larger CRTs or most LCD panels—might be cheaper to repair than to replace. If you decide to repair the monitor, your best bet is to either contact the company from which you purchased the display or contact one of the companies that specializes in monitor depot repair. If your CRT monitor has a 15" diagonal measurement or less, consider replacing it with a unit that is 17" or larger because repair costs on small monitors come close to replacement costs and large monitors aren't much more expensive these days.

Depot repair means you send in your display to repair specialists who either fix your particular unit or return an identical unit they have already repaired. This usually is accomplished for a flat-rate fee; in other words, the price is the same no matter what they have done to repair your actual unit.

Because you usually get a different (but identical) unit in return, they can ship out your repaired display immediately upon receiving the one you sent in, or even in advance in some cases. This way, you have the least amount of downtime and can receive the repaired display as quickly as possible. In some cases, if your particular monitor is unique or one they don't have in stock, you must wait while they repair your specific unit.

Troubleshooting a failed monitor is relatively simple. If your display goes out, for example, a swap with another monitor can confirm that the display is the problem. If the problem disappears when you change the display, the problem is almost certainly in the original display or the cable; if the problem remains, it is likely in the video adapter or PC itself.

Many of the better quality, late-model monitors have built-in self-diagnostic circuitry. Check your monitor's manual for details. Using this feature, if available, can help you determine whether the problem is really in the monitor, in a cable, or somewhere else in the system. If self diagnostics produce an image onscreen, look to other parts of the video subsystem for your problem.

The monitor cable can sometimes be the source of display problems. A bent pin in the connector that plugs in to the video adapter can prevent the monitor from displaying images, or it can cause color shifts. Most of the time, you can repair the connector by carefully straightening the bent pin with sharp-nosed pliers. A loose cable or DVI/VGA adapter can also cause color shifts; tighten the cable and adapter securely.

If the pin breaks off or the connector is otherwise damaged, you can sometimes replace the monitor cable. Some monitor manufacturers use cables that disconnect from the monitor and video adapter, whereas others are permanently connected. Depending on the type of connector the device uses at the monitor end, you might have to contact the manufacturer for a replacement.

If you narrow down the problem to the display, consult the documentation that came with the monitor or call the manufacturer for the location of the nearest factory repair depot. Third-party depot repair service companies are also available that can repair most displays (if they are no longer covered by a warranty); their prices often are much lower than factory service. Check the Vendor List on the disc for several companies that do depot repair of computer monitors and displays.

Caution

You should *never* attempt to repair a CRT monitor yourself. Touching the wrong component can be fatal. The display circuits can hold extremely high voltages for hours, days, or even weeks after the power is shut off. A qualified service person should discharge the cathode ray tube and power capacitors before proceeding.

For most displays, you are limited to making simple adjustments. For color displays, the adjustments can be quite formidable if you lack experience. Use the OSD controls to adjust color, brightness, picture size, and other settings. To quickly adjust an LCD, try the auto-tune feature available on many models. Even factory service technicians often lack proper documentation and service information for newer models; they usually exchange your unit for another and repair the defective one later. Never buy a display for which no local factory repair depot is available.

If you have a problem with a display or an adapter, it pays to call the manufacturer, who might know about the problem and make repairs available. Sometimes, when manufacturers encounter numerous problems with a product, they might offer free repair, replacements, or another generous offer that you would never know about if you did not call.

Remember, also, that many of the problems you might encounter with modern video adapters and displays are related to the drivers that control these devices rather than to the hardware. Be sure you have the latest and proper drivers before you attempt to have the hardware repaired; a solution might already be available.

Troubleshooting Monitors

Problem

No picture.

Solution

If the LED on the front of the monitor is yellow or flashing green, the monitor is in power-saving mode. Move the mouse or press Alt+Tab on the keyboard and wait up to 1 minute to wake up the system if the system is turned on.

If the LED on the front of the monitor is green, the monitor is in normal mode (receiving a signal), but the brightness and contrast are set incorrectly; adjust them.

If no lights are lit on the monitor, check the power and power switch. Check the surge protector or power director to ensure that power is going to the monitor. Replace the power cord with a known-working spare if necessary. Retest. Replace the monitor with a known-working spare to ensure that the monitor is the problem.

Check data cables at the monitor and video card end.

Problem

Jittery picture quality.

Solution

LCD monitors. Use display-adjustment software or onscreen menus to reduce or eliminate pixel jitter and pixel swim.

All monitors. Check cables for tightness at the video card and the monitor (if removable):

- Remove the extender cable and retest with the monitor plugged directly into the video card. If the extended cable is bad, replace it.
- Check the cables for damage; replace as needed.
- If problems are intermittent, check for interference. (Microwave ovens near monitors can cause severe picture distortion when turned on.)

CRT monitors. Check refresh-rate settings; reduce them until acceptable picture quality is achieved:

- Use onscreen picture adjustments until an acceptable picture quality is achieved.
- If problems are intermittent and can be "fixed" by waiting or gently tapping the side of the monitor, the monitor power supply is probably bad or has loose connections internally. Service or replace the monitor.

Troubleshooting Video Cards and Drivers

Problem

Display works in DOS (command-prompt mode) but not in Windows.

Solution

If you have an acceptable picture quality in MS-DOS mode (system boot) but no picture in Windows, most likely you have an incorrect or corrupted video driver installed in Windows. Boot Windows 9x/Me in Safe Mode (which uses a VGA driver), boot Windows 2000/XP in Enable VGA mode, or install the VGA driver and restart Windows. If Safe Mode or VGA Mode works, get the correct driver for the video card and reinstall.

If you have overclocked your card with a manufacturer-supplied or third-party utility, you might have set the speed too high. Restart the system in Safe Mode, and reset the card to run at its default speed. If you have adjusted the speed of AGP/PCI slots in the BIOS setup program, restart the system, start the BIOS setup program, and reset the AGP and PCI slots to run at the normal speed.

Problem

Can't replace built-in video card with add-on PCI, AGP, or PCI Express video card.

Solution

Check with the video card and system vendor for a list of acceptable replacement video cards. Try another video card with a different chipset. Check the BIOS or motherboard for jumper or configuration settings to disable built-in video. Place the add-on card in a different PCI slot. Be sure the card is fully inserted into the slot.

Problem

Can't select desired color depth and resolution combination.

Solution

Verify that the card is properly identified in Windows and that the card's memory is working properly. Use diagnostic software provided by the video card or chipset maker to test the card's memory. If the hardware is working properly, check for new drivers. Use the vendor's drivers rather than the ones provided with Windows.

Problem

Can't select desired refresh rate.

Solution

Verify that the card and monitor are properly identified in Windows. Obtain updated drivers for the card and monitor.

Problem

Can't adjust OpenGL or Direct3D (DirectX) settings.

Solution

Install the graphic card or chipset vendor's latest drivers instead of using the drivers included with Microsoft Windows. Standard Microsoft drivers often don't include 3D or other advanced dialog boxes.

Problem

Can't enable secondary monitor.

Solution

If you are using a dual-head graphics card, make sure the secondary monitor has been enabled in the manufacturer's driver. This can require you to open the Advanced settings for your driver. If you are using two video cards in an SLI (NVIDIA) or CrossFire (ATI) configuration, you must disable SLI or CrossFire before you can enable additional monitors. If you are using an AGP and a PCI video card in separate slots, check the BIOS configuration for primary VGA BIOS. Change the current setting and restart the system. Update video card drivers.

Problem

Can't enable SLI operation.

Solution

Make sure the MIO (SLI bridge) device is properly installed between your video cards (refer to [Figure 13.14](#)). If you are not using identical video cards, you must use NVIDIA ForceWare v81.85 or new drivers to enable SLI operation. Make sure both cards use the same GPU family (both must use a 7800-series GPU or a 6800-series GPU, and so on). Make sure SLI operation is enabled in the ForceWare driver.

Problem

Can't enable CrossFire operation.

Solution

If you use the Radeon X800, X850, or X1800 cards, make sure you have paired up a CrossFire Edition and standard Radeon card from the same GPU family. Also, make sure you have properly connected the CrossFire Edition and standard card to each other via the DMS and DVI ports. Update ATI CATALYST display drivers to the latest production version. Be sure you have enabled CrossFire in your display driver.

DisplayMate

DisplayMate is a unique diagnostic and testing program designed to thoroughly test your video adapter and display. It is somewhat unique in that most conventional PC hardware diagnostics programs do not emphasize video testing the way this program does.

I find it useful not only in testing whether a video adapter is functioning properly, but also in examining video displays. You easily can test the image quality of a display, which allows you to make focus, centering, brightness and contrast, color level, and other adjustments much more accurately than before. If you are purchasing a new monitor, you can use the program to evaluate the sharpness and linearity of the display and to provide a consistent way of checking each monitor you are considering. If you use projection systems for presentations as I do in my PC hardware seminars you will find it invaluable for setting up and adjusting the projector.

DisplayMate also can test a video adapter thoroughly. It sets the video circuits into each possible video mode so you can test all its capabilities. It even helps you determine the performance level of your card, both with respect to resolution and colors as well as speed. You can then use the program to benchmark the performance of the display, which enables you to compare one type of video adapter system to another. The Video Edition also supports various types of multimedia projectors and TVs used in home theater and presentation environments.

See the Vendor List on the disc for more information on DisplayMate (formerly Sonera) Technologies, or visit www.displaymate.com.

Some video-card vendors supply a special version of DisplayMate for use in diagnostics testing.

Chapter 14. Audio Hardware

Since the first edition of this book was published in 1988, a lot has happened to audio hardware. Although rudimentary audio capabilities were part of the original IBM PC of 1981 and its many successors, audio was used on early computers for troubleshooting rather than for creative tasks. Computers used beeps for little other than to signal problems such as a full keyboard buffer or errors during the power on self test (POST) sequence. The Macintosh, first introduced in 1984, included high-quality audio capabilities in its built-in hardware, but PCs did not gain comparable audio capabilities until the first add-on sound cards from companies such as Ad Lib and Creative Labs were developed in the late 1980s.

Thanks to competition among many companies, we now enjoy widely supported *de facto* hardware and software standards for audio. Audio hardware has gone from being an expensive, exotic add-on to being an assumed part of virtually any system configuration.

Today's PC audio hardware might take one of the following forms:

- An audio adapter on a PCI expansion card that you install into a bus slot in the computer.
- An AC'97 sound codec chip located on the motherboard, using sound chips from companies such as Crystal, Analog Devices, Sigmatel, ESS, or others.
- Hardware that's integrated into the motherboard's main chipset. Intel, SiS, NVIDIA, Aopen, and VIA have all released products in this category at one point or another.

Regardless of their location, the audio features use jacks for speakers and a microphone. In addition, many of them provide dedicated jacks for MIDI hardware (older cards usually provided an analog game port for joysticks). As you will see later in this chapter, many mid-range and high-end audio adapters also support sophisticated digital audio input and output. On the software side, the audio adapter requires the support of a driver that you install either directly from an application or in your computer's operating system. This chapter focuses on the audio products found in today's PCs, their uses, and how you install and operate them.

Early PC Audio Adapters

When the first audio adapters were introduced in the late 1980s by companies such as AdLib, Roland, and Creative Labs, they were aimed squarely at a gaming audience, were not compatible with each other, and often cost more than \$100.

Note

About the same time as the release of the Creative Labs Game Blaster, hardware supporting the Musical Instrument Digital Interface (MIDI) became available for the PC. At this time, however, such hardware was used only in very specialized recording applications. As MIDI support became a more common feature in musical instruments, though, it also became a more affordable PC add-on.

The Game Blaster, which was compatible with only a handful of games, was soon replaced by the Sound Blaster, which was compatible with the AdLib sound card and the Creative Labs Game Blaster card, enabling it to support games that specified one sound card or the other. The Sound Blaster included a built-in microphone jack, stereo output, and a MIDI port for connecting the PC to a synthesizer or other electronic musical instrument. This established a baseline of features that would be supported by virtually all other sound cards and onboard sound features up to the present. Finally, the audio adapter had the potential for uses other than games. The follow-up Sound Blaster Pro featured improved sound when compared to the original Sound Blaster. The Sound Blaster Pro and its successors eventually triumphed over earlier rivals to become de facto standards for PC sound reproduction.

Note

Unlike de jure standards such as the IEEE-1394 port, which is an official standard of the IEEE organization, de facto standards are those that develop informally due to the widespread acceptance of the market leader's products in a particular segment of the marketplace. The Sound Blaster Pro is just one of many examples of a de facto standard: IBM's VGA card became a de facto baseline standard for video, and HP and Apple's different printer languages (HP PCL and Adobe PostScript) became de facto standards for printers.

Limitations of Sound Blaster Pro Compatibility

Through the mid-1990s, while MS-DOS was the standard gaming platform, many users of nonCreative Labs sound cards struggled with the limitations of their hardware's imperfect emulation of the Sound Blaster Pro. Unfortunately, some cards required two separate sets of hardware resources, using one set of IRQ, DMA, and I/O port addresses for native mode and a second set for Sound Blaster Pro compatibility. Others worked well within Windows or within an MS-DOS session running with Windows in the background but required the user to install a DOS-based Terminate and Stay Resident (TSR) driver program to work in MS-DOS itself.

However, the rise of 32-bit Windows games has made audio support very simple by comparison. Windows

applications use the operating system's drivers to interface with hardware, relieving the software developer from needing to write different code for different sound cards, 3D graphics cards, and so on. For 3D sound and gaming graphics, Microsoft Windows uses a technology called DirectX, which was first introduced in December 1995; the current version is DirectX 9.0c.

DirectX and Audio Adapters

Microsoft's DirectX is a series of application program interfaces (APIs) that sit between multimedia applications and hardware. Unlike MS-DOS applications that required developers to develop direct hardware support for numerous models and brands of audio cards, video cards, and game controllers, Windows uses DirectX to "talk" to hardware in a more direct manner than normal Windows drivers do. This improves program performance and frees the software developer from the need to change the program to work with different devices. Instead, a game developer must work with only the DirectX sound engine, DirectX 3D renderer, and DirectX modem or network interface routines.

►► For more information about DirectX and sound hardware, see "[3D Audio](#)," p. [963](#).

Thanks to DirectX, sound card and chipset developers are assured that their products will work with recent and current versions of Windows. However, if you still enjoy playing MS-DOSbased games, current audio adapters, chipsets, and integrated audio solutions still might present a compatibility challenge to you because of fundamental hardware differences between the ISA expansion slots used by classic Creative Labs and other sound cards and PCI slots, chipsets, and integrated audio. The only way to ensure audio compatibility with these legacy programs is to use a Sound Blaster Procompatible ISA sound card (if you can obtain one) on a system running DOS 6.x, possibly with Windows 3.x as well, depending on the nature of the application.

►► For more information about using PCI sound hardware with MS-DOS games, see "[Legacy \(MS-DOS and Gameport\) Game Support Issues](#)," p. [953](#).

PC Multimedia History

Virtually every computer on the market today is equipped with some type of audio adapter and a 0CD-ROM or CD-ROMcompatible drive such as a CD-RW or DVD drive. Computers equipped with an audio adapter and a CD-ROMcompatible drive are often referred to as *multimedia* PCs after the old MPC-1, MPC-2, and MPC-3 standards that were used to rate early multimedia computers. Since 1996, all computers with onboard sound and a CD-ROM or compatible optical drive have exceeded MPC-3 standards by increasingly huge margins.

Note

For more information about the MPC series of multimedia standards, see the section "Multimedia" in [Chapter 20](#) of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the disc accompanying this book.

Because the MPC specifications reflect multimedia's past, users who want to know what comes next need to turn somewhere else for guidance. Microsoft and Intel have jointly produced a series of PC System Design Guides. Although the PC System Design Guide's last version is known as PC 2001 and no further updates are planned, it and its predecessor (PC 99) are still useful references for multimedia hardware and software design and are still widely followed by the industry. For example, most I/O ports on recent systems use the PC 99 color-coding standard.

Note

You can download the PC 2001 and earlier PC System Design Guides from Microsoft's website at <http://www.microsoft.com/whdc/system/platform/pcdesign/desguide/pcguides.mspx>.

Updated Microsoft-specific system design information is available at <http://www.microsoft.com/whdc/system/platform/pcdesign/desguide/default.mspx>.

Although virtually every computer is a "multimedia PC" today, the features of the audio adapter or onboard audio solution in your system will help determine how satisfied you will be with the wide range of specialized uses for multimedia-equipped systems.

Later in this chapter, you learn more about the features you need to specify to ensure your audio adapterregardless of typeis ready to work for you.

Audio Adapter Features

To make an intelligent purchasing decision, you should be aware of some audio adapter basic components and the features they provide, as well as the advanced features you can get on better audio adapters. The following sections discuss the features you should consider while evaluating audio adapters for your PC.

Basic Connectors

Most audio adapters have the same basic external connectors. These 1/8" minijack connectors provide the means of passing sound signals from the adapter to speakers, headphones, and stereo systems, and of receiving sound from a microphone, CD player, tape player, or stereo. The four types of connectors your audio adapter should have at a minimum are shown in [Figure 14.1](#). Note that computers with onboard audio also feature some or all of these jacks.

Figure 14.1. The basic input and output connectors that most audio adapters have in common.

[\[View full size image\]](#)

The jacks shown in [Figure 14.1](#) are usually labeled, but when setting up a computer on or under a desk, the labels on the back of the PC can be difficult to see. One of the most common reasons a PC fails to produce any sound is that the speakers are plugged into the wrong socket. To avoid this problem, many consumer-oriented audio cards color-code the jacks according to specifications found in the PC 99 Design Guide available from the Microsoft website. The color-coding can vary on some audio adapters (or not be present at all). Regardless, the basic set of connections included on most audio cards is as follows:

- *Stereo line, or audio, out connector (lime green)*. The line-out connector is used to send sound signals from the audio adapter to a device outside the computer. You can hook up the cables from the line-out connector to stereo speakers, a headphone set, or your stereo system. If you hook up the PC to your stereo system, you can have amplified sound.
- *Stereo line, or audio, in connector (light blue)*. With the line-in connector, you can record or mix sound signals from an external source, such as a stereo system or VCR, to the computer's hard disk.
- *Rear out or speaker/headphone connector (no standard color)*. Older sound cards often provided an amplified jack supplying up to 4 watts of power for use with unpowered speakers or headphones along with the line-out connector. Today, you are more likely to find this jack used for rear speakers in four-speaker setups. The rear out jack often is disabled by default; check your audio adapter

properties or setup program to see whether you need to enable this port when you connect rear speakers.

Note

If you have only a single speaker/line-out connector, you must carefully adjust your mixer volume control and the volume control on your amplified speakers to find the best quality sound. Don't use powered speakers with an already-amplified sound if you can avoid it.

- *Microphone, or mono, in connector (pink)*. The mono-in connector is used to connect a microphone for recording your voice or other sounds to disk. This microphone jack records in mononot in stereoand is therefore not suitable for high-quality music recordings. Many audio adapter cards use Automatic Gain Control (AGC) to improve recordings. This feature adjusts the recording levels on-the-fly. A 600ohm10,000ohm dynamic or condenser microphone works best with this jack. Some inexpensive audio adapters use the line-in connector instead of a separate microphone jack.
- *Game port (gold)*. The game port (also called the joystick connector) is a 15-pin, D-shaped connector that can connect to any standard joystick or game controller. Sometimes the joystick port can accommodate two joysticks if you purchase an optional Y-adapter. Many computers already contain a joystick port as part of a multifunction I/O circuit on the motherboard or an expansion card. If this is the case, you must note which port your operating system or application is configured to use when connecting the game controller. Some of the latest sound cards and systems with onboard sound omit this connector or put this connector on an optional bracket because most recent game controllers support USB connectors.
- *MIDI connector (gold)*. Audio adapters typically use the same joystick port as their MIDI connector. Two of the pins in the connector are designed to carry signals to and from a MIDI device, such as an electronic keyboard. In most cases, you must purchase a separate MIDI connector from the audio adapter manufacturer that plugs into the joystick port and contains the two round, 5-pin DIN connectors used by MIDI devices, plus a connector for a joystick. However, high-end sound cards might use 5-pin MIDI ports connected to a daughtercard or a breakout box (see [Figure 14.3](#), later in this chapter). Because their signals use separate pins, you can connect the joystick and a MIDI device at the same time. You need this connector only if you plan to connect your PC to external MIDI devices. You can still play the MIDI files found on many websites by using the audio adapter's internal synthesizer.

Note

Some recent systems with onboard audio lack the joystick/MIDI connector, but you can use digital game controllers that feature a USB connector to attach your game controllers to the USB port. And, as mentioned earlier, you can attach MIDI devices through the same USB connector with a suitable interface box.

In addition to the external connections, most sound cards feature at least one (and possibly multiple) internal CD-audio connectors. Most audio adapters have an internal 4-pin connector you can use to plug an internal optical drive directly into the audio adapter, using a small round cable. This connection enables the drive to send analog audio signals from the disc directly to the audio adapter, so you can play the sound through the computer's speakers. Some sound cards use a different connector than the CD-ROM, whereas others use the same type of connector as the CD-ROM (see [Figure 14.2](#)).

Figure 14.2. Typical CD-ROM analog audio cables.

Figure 14.3. The Sound Blaster Audigy 2 ZS Platinum (left) includes the Audigy 2 ZS Drive internal, front-panel breakout box (right) to support the Audigy 2 ZS's many features.

- 1. 6-channel digital out
- 2. Line in
- 3. Microphone in
- 4. Line out 1 (front/headphones; used with all analog speakers)
- 5. Line out 2 (rear; used with 4.1, 5.1, 6.1, 7.1 analog speakers)
- 6. Line out 3 (center/subwoofer; used with 5.1, 6.1, 7.1 analog speakers)

- 7. SB1394 ports (one each on the card bracket and on the Audigy drive)
- 8. Connection between Audigy 2 card and Audigy 2 Drive breakout box
- 9. Optical in/out
- 10. Coaxial SPDIF in/out
- 11. Headphone out
- 12. Line in/Mic IN
- 13. Left/right Aux in
- 14. MIDI in/out

Note

See [Figure 14.10](#), later in this chapter, for an example of a typical sound card with analog and digital audio cables attached.

To play audio CDs, you have two choices: The playback can be either analog or digital. Analog playback is supported via an analog audio cable connected between the drive and sound card. This cable does not carry data from the CD-ROM to the system bus; it connects the analog audio output of the CD-ROM drive directly to the audio amplifier in the sound card. With many drives and sound cards especially on older systems if you don't connect an analog audio cable between the drive and card, you might be unable to play music CDs or hear some game audio.

Most newer drives and cards support digital playback as well as the standard direct analog connection. If your drive and card support digital playback, open the Control Panel in Windows, click the Multimedia icon, and then select the CD Music tab. You should see settings for changing the default drive for playing CD

music and a box you can check to enable digital CD audio for that drive. If the box is grayed out (meaning you can't check it), digital audio is not supported for that drive or card.

Using digital audio enables multiple drives to play audio CDs. Typically, a sound card has only a single analog audio connector, so if you have multiple optical drives, only one can have an analog audio connection to the sound card for playing audio CDs. If you want to play audio CDs on multiple drives, you must either enable digital CD audio for those drives or purchase a CD audio Y-cable. By either enabling digital audio or installing an analog audio cable, you should be able to play audio CDs with any given CD/DVD drive.

Note

Many recent versions of audio player programs, such as Windows Media Player, can perform digital audio playback without using the two-wire digital audio cable between the CD-ROM drive and sound card. Instead, these programs read the CD music tracks and convert them on-the-fly into digital form.

Connectors for Advanced Features

Many of the newest sound cards and motherboards with onboard sound are designed for advanced gaming, DVD audio playback, and sound production uses and have additional connectors to support these uses, such as the following:

- *MIDI in and MIDI out.* Some advanced sound cards don't require you to convert the game port (joystick port) to MIDI interfacing by offering these ports on a separate external connector. This permits you to use a joystick and have an external MIDI device connected at the same time. Typical location: external device.
- *SPDIF (also called SP/DIF) in and SPDIF out.* The Sony/Philips Digital Interface receives digital audio signals directly from compatible devices without converting them to analog format first. Typical location: external device. (SPDIF interfaces are also referred to by some vendors as "Dolby Digital" interfaces.)

Note

SPDIF connectors use cables with the standard RCA jack connector but are designed to work specifically at an impedance of 75ohms the same as composite video cables. Thus, you can use RCA-jack composite video cables with your SPDIF connectors. Although audio cables are also equipped with RCA jacks, their impedance is different, making them a less desirable choice.

- *CD SPDIF.* Connects compatible CD-ROM drives with SPDIF interfacing to the digital input of the sound card. Typical location: side of audio card. The cable used resembles the cable shown in [Figure 14.2](#), but it uses only two wires. See [Figure 14.10](#), later in this chapter, for an example of a typical sound card using a CD SPDIF cable.
- *TAD in.* Connects internal modems with Telephone Answering Device support to the sound card for sound processing of voice messages. Typical location: side of audio card.

- *Digital DIN out.* This supports multispeaker digital speaker systems, such as those produced by Cambridge for use with the SoundBlaster Live! series. Typical location: external device.
- *Optical SPDIF in/out.* This supports home theater and digital speaker systems with optical inputs. Typical locations: rear of card or external device.
- *Aux in.* Provides input for other sound sources, such as a TV tuner card. Typical location: side of audio card.
- *I2S in.* This enables the sound card to accept digital audio input from an external source, such as two-channel decoded AC-3 from DVD decoders and MPEG-2 Zoom Video. Typical location: side of audio card.
- *USB port.* This enables the sound card to connect to USB speakers, game controllers, and other types of USB devices. The Hercules Game Theater XP series, the first sound card with built-in USB ports, supports USB 1.1 only. Typical location: external breakout box.
- *IEEE 1394.* This enables the sound card to connect to IEEE 1394-compatible DV camcorders, scanners, hard drives, and other devices. The Creative Labs Sound Blaster Audigy, Audigy 2 series, and Hercules Digifire 7.1 all feature one or more IEEE 1394 ports. Typical location: card bracket or external cable or breakout box.

Sometimes these additional connectors are found on the card itself, or sometimes they are attached to an internal or external breakout box, daughtercard, or external rack. Among others, the Platinum family of Audigy and X-Fi sound cards from Creative are two-piece units. Although details vary from card to card, most two-piece models feature a PCI-based sound card with basic I/O ports and a separate internal or external component with additional and more advanced I/O ports. The Creative X-Fi Platinum, for example, routes its additional connections to an internal breakout box that fits into an unused 5 1/4" drive bay (see [Figure 14.3](#)). The Audigy 2 ZS Platinum Pro, on the other hand, uses an external breakout box with the same connection options.

[Figure 14.4](#) shows Chaintech's AV-710 audio adapter card with the internal connectors common on today's 3D sound cards.

Figure 14.4. Chaintech's AV-710 is a typical example of a mid-range 3D sound card with 7.1 audio support.

Adding Advanced Sound Features Without Replacing Onboard Audio

Traditionally, audio card upgrades have been designed specifically for users of desktop computers, leaving the growing number of notebook computer users out in the cold if they decided that the bare-bones features of their integrated audio weren't sufficient. However, several companies have recently developed USB-based audio processors that can be used by both notebook and desktop computers.

When you consider a USB-based solution, keep in mind that, unlike a normal sound card upgrade, you don't need to disable your existing onboard sound or remove a sound card. USB-based audio can coexist with existing sound cards. Typically, as with most hardware, the most recently installed hardware in a category becomes the default, but you can switch back to the original audio hardware through the Windows Control Panel Sound properties sheet.

Beyond the ability to add audio to almost any recent system, USB-based audio is particularly appealing if your current sound card or onboard audio doesn't support 5.1 or 7.1 audio, can't digitize sound at 24-bit/96KHz rates, or lacks digital outputs. [Table 14.1](#) lists the major features of current and recent USB-based audio products.

Table 14.1. USB-Based Audio Processors

Manufacturer	Product	Output Quality	Recording Quality	Speaker Support	Notes
Audiotrak	MAYA EX	16-bit/48KHz	16-bit/48KHz	Up to 5.1	Dolby Digital AC-3
Audiotrak	MAYA EX7	16-bit/48KHz	16-bit/48KHz	Up to 7.1	Dolby Digital AC-3
Creative Labs	Sound Blaster Extigy	24-bit/96KHz	16-bit/48KHz	Up to 5.1	Dolby Digital AC-3
Creative Labs	Sound Blaster MP3+	16-bit/48KHz	16-bit/48KHz	2.1	Optical SPDIF input/output
Creative Labs	Audigy 2 NX	24-bit/96KHz	24-bit/96KHz	Up to 7.1	Dolby Digital AC-3, EX; supports Hi-Speed USB
Hercules	Gamesurround MUSE Pocket	16-bit/48KHz	16-bit/48KHz	Up to 5.1	No SPDIF connector
M-Audio	Sonica	24-bit/96KHz	N/A	Up to 5.1	Dolby Digital AC-3 with optical output only
M-Audio	Sonica Theater	24-bit/96KHz	24-bit/96KHz	Up to 7.1	Dolby Digital AC-3
Philips	PSC805 Aurilium	24-bit/96KHz	N/A	Up to 5.1	Dolby Digital AC-3; supports Hi-Speed USB
TerraTec	Aureon 5.1 USB	16-bit/48KHz	16-bit/48KHz	Up to 5.1	Dolby Digital AC-3
Creative Labs	Audigy 2 ZS Notebook	24-bit/192KHz	24-bit	Up to 7.1	

The connectors and controls on the Creative Labs Sound Blaster Audigy 2 NX are shown in [Figure 14.5](#).

Figure 14.5. The Sound Blaster Audigy 2 NX expands bare-bones onboard audio by adding advanced I/O and sampling features similar to those found on the Sound Blaster Audigy 2 series.

Before you purchase a new sound card or USB-based audio solution for a desktop computer, you should check your system or motherboard documentation to see whether you already have six-channel audio onboard. If your motherboard features six-channel (5.1) or better audio output but the only ports built in to the rear of the motherboard are for a normal stereo (2.0/2.1) configuration, you need to add a header cable to the motherboard similar to the one shown in [Figure 14.6](#). If the motherboard did not ship with the header cable, contact the vendor.

Figure 14.6. The built-in ports on the ATX port cluster (left) support stereo output, but the header cable (center) adds support for four-channel and six-channel audio and digital sound.

- | | |
|------------------------|---|
| 1. Microphone in | 5. Speaker out (center/subwoofer) |
| 2. Line in | 6. Coaxial SPDIF digital audio out |
| 3. Speaker out (front) | 7. Optical SPDIF digital audio out |
| 4. Speaker out (rear) | 8. Header cable connection to motherboard |

Volume Control

With virtually all recent sound cards, the volume is controlled through a Windows Control Panel speaker icon that can also be found in the system tray (near the onscreen clock). If you're switching from a bare-bones stereo sound card to a more sophisticated one featuring Dolby Digital 5.1, 6.1, or 7.1 output or input, you will need to use the mixing options in the volume control to select the proper sources and appropriate volume levels for incoming and outgoing audio connected to the card or a breakout box. Keep in mind that if you are sending sound to an external audio receiver, you will need to adjust the volume on that device as well.

If the PC speakers are amplified but you aren't hearing any sound, remember to check that the power is on, the volume control on the speakers is turned up, and the correct speakers are selected and properly connected. If the sound card has a thumbwheel volume control (as some older ones do), make sure it is turned up as well.

MIDI Support Features

At one time, when evaluating audio adapters, you had to decide whether to buy a monophonic or stereophonic card. Today, all audio adapters are stereophonic and can play music using the MIDI standard, which plays scores using either synthesized instruments or digital samples stored on the audio adapter or in RAM.

Stereophonic cards produce many voices concurrently and from two sources. A voice is a single sound produced by the adapter. A string quartet uses four voices, one for each instrument. On the other hand, a polyphonic instrument, such as a piano, requires one voice for each note of a chord. Thus, fully reproducing the capabilities of a pianist requires 10 voicesone for each finger. The more voices an audio adapter is capable of producing, the better the sound fidelity. The best audio adapters on the market today can produce up to 1,024 simultaneous voices.

Early audio adapters used FM synthesis for MIDI support; the Yamaha OPL2 (YM3812) featured 11 voices, whereas the OPL3 (YMF262) featured 20 voices and stereophonic sound. However, virtually all audio adapters today use recorded samples for MIDI support; audio adapters using this feature are referred to as *wavetable* adapters.

Wavetable audio adapters use digital recordings of real instruments and sound effects instead of imitations generated by an FM chip. When you hear a trumpet in a MIDI score played on a wavetable sound card, you hear the sound of an actual trumpet, not a synthetic imitation of a trumpet. The first cards featuring wavetable support stored 1MB of sound clips embedded in ROM chips on the card or on an optional daughtercard. However, with the widespread use of the high-speed PCI bus for sound cards and large amounts of RAM in computers, most soundcards now use a so-called "soft wavetable" approach, loading 2MB8MB of sampled musical instruments into the computer's RAM.

While early games supported only digitized audio samples (because most early sound cards had very poor MIDI support), late DOS games such as DOOM began to exploit the widespread wavetable-based MIDI support found on most mid-1990s and more recent sound cards. With all current sound hardware supporting wavetable MIDI and the improvements in DirectX 8.x and above for MIDI support, MIDI sound has become far more prevalent for game soundtracks. Many websites also offer instructions for patching existing games to allow MIDI support. Whether you play the latest games or like music, good MIDI performance is likely to be important to you.

The most important factor for high-performance MIDI is the number of hardware voices. Even the best sound cards, such as Creative Labs' Sound Blaster Audigy 2 series, support only 64 voices in hardware; the remainder of the voices required by a MIDI soundtrack must come from software. If your sound card supports only 32 MIDI voices in hardware or uses software synthesis only, consider replacing it with a newer model. Many of the models currently on the market support more than 500 simultaneous voices and 64 hardware voices for under \$50.

Data Compression

Virtually all audio adapters on the market today can easily produce CD-quality audio, which is sampled at 44.1KHz. At this rate, recorded files (even of your own voice) can consume more than 10MB for every minute of recording. To counter this demand for disk space, many audio adapters include their own data-compression capability. For example, the Sound Blaster series includes on-the-fly compression of sound files in ratios of 2: 1, 3: 1, and 4: 1.

Most manufacturers of audio adapters use an algorithm called Adaptive Differential Pulse Code Modulation

(ADPCM) compression (it's also called IMA-ADPCM), which was developed by the Interactive Multimedia Association (IMA) to reduce file size by more than 4:1. IMA-ADPCM compresses 16-bit linear samples down to 4 bits per sample. However, a simple fact of audio technology is that when you use such compression, you lose sound quality. Unfortunately, no standard exists for the use of ADPCM. For example, although both Apple and Microsoft support IMA-ADPCM compression, they implement it in different ways. Apple's standard AIFF and Microsoft's standard WAV file formats are incompatible with each other unless you use a media player that can play both.

When you install an audio adapter, several codecs (programs that perform compression and decompression) are installed. Typically, some form of ADPCM is installed along with many others. To see which codecs are available on your system, open the Windows Control Panel and open the Multimedia icon (Windows 9x), the Sounds and Multimedia icon (Windows 2000), or the Sounds and Audio Devices icon (Windows XP). In Windows 9x, click the Devices tab followed by the plus sign next to Audio Compression to see the installed codecs. In Windows 2000 and Windows XP, click the Hardware tab, followed by Audio Codecs and Properties. The codecs are listed in order of priority, highest to lowest. You can also change the priority if you prefer a different order of priority. If you create your own recorded audio for use on another computer, both computers must use the same codec. You can select which codec you want to use for recording sounds with most programs, including the Windows Sound Recorder.

The most popular compression standard is the Motion Pictures Experts Group (MPEG) standard, which works with both audio and video compression and is gaining support in the non-PC world from products such as DVD players. MPEG by itself provides a potential compression ratio of 30:1, and largely because of this, full-motion-video MPEG DVD and CD-ROM titles are now available. The popular MP3 sound compression scheme is an MPEG format, and it can be played back on most versions of the Windows Media Player, as well as by various other audio player programs and devices.

Multipurpose Digital Signal Processors

Many audio adapters use digital signal processors (DSPs) to add intelligence to the adapter, freeing the system processor from work-intensive tasks, such as filtering noise from recordings or compressing audio on-the-fly.

The Sound Blaster Audigy 2 ZS's CA0102-ICT programmable DSP, for example, supports hardware sound acceleration needed by the latest version of Microsoft DirectX/DirectSound 3D, which enables multiple sounds to be played at the same time to synchronize with the onscreen action in a video game. The DSP can be upgraded with software downloads to accommodate more simultaneous audio streams. The widespread use of DSPs in better-quality audio adapters enables you to upgrade them through software instead of the time-consuming, expensive process of physical replacement.

For additional examples of DSPs, see the section "[Who's Who in Audio](#)," later in this chapter.

Sound Drivers

As with many PC components, a software driver provides a vital link between an audio adapter and the application or operating system that uses it. Operating systems such as Windows 9x/Me and Windows 2000/XP include a large library of drivers for most of the audio adapters on the market (Windows NT 4.0 also supports some sound hardware but not as much as other versions of Windows). In most cases, these drivers are written by the manufacturer of the audio adapter and distributed only by Microsoft. You might find that the drivers that ship with the adapter are more recent than those included with the operating system. Although traditionally the best place to find the most recent drivers for a piece of hardware has been the manufacturer's own website or other online service, Windows Me, 2000, and XP prefer digitally signed drivers that have been certified by the Microsoft Hardware Quality Labs. You might find these drivers

available at the vendor's own website, but you can also download and install them automatically through Windows Update.

Any DOS applications you might still use do not typically include as wide a range of driver support as an operating system, but you should find that most games and other programs support the Sound Blaster adapters. If you are careful to buy an adapter that is compatible with Sound Blaster, you should have no trouble finding driver support for all your applications. Older ISA Sound Blaster cards provided hardware support for DOS games, but modern models (including the Sound Blaster Audigy and X-Fi series), as well as most comparable sound cards, require you to run software drivers to obtain Sound Blaster compatibility for DOS games. This software must be run before the game starts.

If your game program locks up when you try to detect the sound card during configuration, set the card type and settings manually. This is often a symptom of inadequate emulation for Sound Blaster by a third-party card. If you have problems, check the game developer's or audio adapter's website for patches or workarounds.

Choosing the Best Audio Adapter for Your Needs

Although sound features in computers have become commonplace, the demand for sophisticated uses for sound hardware have grown and demanded more and more powerful hardware. If your idea of a perfect multimedia PC includes any of the following, the plain-vanilla multimedia hardware found in many of today's PCs won't be sufficient:

- Realistic 3D and 360° sound for games
- Theater-quality audio for DVD movies
- Voice dictation and voice command
- Creating and recording MIDI, MP3, CD-Audio, and WAV audio files

[Table 14.2](#) summarizes the additional hardware features and software you'll need to achieve the results you want with your high-performance audio adapter. The following sections examine in detail these advanced uses and the features you'll need for each.

Table 14.2. Audio Adapter Intended Uses and Features Comparison

Intended Use	Features You Need	Additional Hardware	Additional Software
Gaming	Game or USB port; 3D sound; audio accelerator	4.1 or greater speaker configuration; game controller	Games
DVD movie playback	5.1 or greater analog or Dolby Digital AC-3 support	5.1 or greater speaker configuration	DVD player program with 5.1 or greater audio support
Voice dictation and voice command	Audio adapter equivalent or better than Sound Blaster 16 and supported by software	Microphone optimized for voice-recognition	Voice-dictation or voice-command software
Creating MIDI files	MIDI-in connector	MIDI keyboard	MIDI composing software
Creating digital music (MP3, WMA) files	Digital connection to CD or DVD drive	CD or DVD drive with digital audio extraction (DAE) support	MP3 or WMA ripping software
Creating WAV (uncompressed audio) files	Line-in/microphone jack	Microphone or other sound source	Sound recording program

Creating CD audio files	Line-in jack	External sound source (microphone, CD audio, or others)	Digital (WAV, MP3, or WMA) to CD audio track conversion program
-------------------------	--------------	---	---

The following sections discuss many of these special uses in detail.

Gaming

Thanks to the widespread availability of audio adapters, game playing has taken on a new dimension. Support for 3D and surround digitized sound and realistic MIDI music in current games has added a level of realism that would otherwise be impossible even with today's sophisticated graphics hardware. Gaming enthusiasts should choose audio solutions with support for four or more speakers and some form of directional sound, such as the Creative Labs EAX technology used in Sound Blaster Live! and the Audigy/Audigy 2 series or Sensaura 3D Positional Audio (3DPA) used by ESS, VideoLogic, Cirrus Crystal Logic, Analog Devices, C-Media, and NVIDIA. Most recent sound cards feature support for one or more of these standards, either through direct hardware support or through software emulation and conversion. As with 3D video cards (refer to [Chapter 13](#), "Video Hardware"), most cards today merely need to work with the 3D audio APIs included in the current revision of Microsoft's DirectX technology.

Any audio adapter built in the last few years will still work with today's games, thanks in large part to the Hardware Emulation Layer (HEL) built into DirectX. HEL emulates the features of newer hardware, such as 3D sound, on older hardware. However, as you can imagine, the task of emulating advanced performance on older hardware can slow down gameplay and doesn't produce sounds as realistic as those available with today's best audio adapters.

Sound Card Minimums for Gameplay

The replacement of the old ISA Sound Blaster Pro standard by PCI sound card standards has helped improve audio performance a great deal, but for the best gameplay with current and forthcoming titles, you need to consider sound cards with the following features:

- *3D audio support in the chipset.* 3D audio means you'll be able to hear sounds appear to move toward you, away from you, and at various angles corresponding to what's happening onscreen. Microsoft's DirectX, version 9.0b, includes support for 3D audio, but you'll have faster 3D audio performance if you use an audio adapter with 3D support built in. DirectX 9.0b works along with proprietary 3D audio APIs, such as Creative's EAX and EAX 2.0, Sensaura's 3D Positional Audio, and the A3D technology from now-defunct Aureal.
- *3D sound acceleration.* Sound cards using chipsets with this feature require very little CPU utilization, which speeds up overall gameplay. For best results, use a chipset that can accelerate a large number of 3D streams; otherwise, the CPU will be bogged down with managing 3D audio. This can slow down gameplay, particularly on systems with processors running under 1GHz or that are running at a high-resolution, high-color depth setting (1,024x768/32-bit).

Features such as these don't necessarily cost a ton of money; many of the mid-range audio adapters on the market (\$50-\$100 at retail) support these features. With new 3D audio chipsets available from a number of vendors, it might be time for you to consider an upgrade if you're heavily into 3D gaming. If you are a gaming enthusiast with money to spend, you should consider upgrading to Creative Labs Sound Blaster X-Fi series sound card. It is the most advanced card in its class, and with its surround sound upmixing, surround simulation, and 24-bit Crystalizer, it is an excellent choice for PC gaming.

Legacy (MS-DOS and Gameport) Game Support Issues

Support for the classic Sound Blaster Pro standard and 15-pin game port were once the primary requirements for a good gaming audio adapter. However, with the rise of great Windows-based games, the development of DirectX, and the replacement of game ports by USB ports, these are no longer issues for many users.

If you need to play MS-DOS games or work with game ports, see [Chapter 16](#) of *Upgrading and Repairing PCs, 15th Anniversary Edition* on the disc packaged with this book to learn about compatibility considerations.

DVD Movies on Your Desktop

You don't need a dedicated DVD player to enjoy the clarity, control, extra features, and excitement of DVD movies. DVD-ROM drives help bring the DVD movie experience to your PC, but having a DVD-ROM and a DVD movie player program is only part of what you need to bring the big screen to your desktop.

To get the most out of your desktop DVD experience, you need the following:

- *DVD playback software that supports Dolby Digital 5.1 or better output.* One of the best choices is Cyberlink's PowerDVD 6.x, available from www.gocyberlink.com.
- *An audio adapter that supports Dolby Digital input from the DVD drive and will output to Dolby Digital 5.1-compatible audio hardware.* Some will remix Dolby 5.1 to work on four-speaker setups if you don't have Dolby 5.1 hardware or will accept S/PDIF AC3 (Dolby Surround) input designed for a four-speaker system; some can also pass through Dolby Digital audio to speakers that can perform the Dolby Digital 5.1 decoding. Some high-end audio adapters now support 6.1 and 7.1 speaker configurations; these also work with Dolby Digital 5.1 sound.
- *Dolby Digital 5.1-compatible stereo receiver and speakers.* Most high-end sound cards with Dolby Digital 5.1 support connection to analog-input Dolby Digital 5.1 receivers, but some, such as the Creative Labs Sound Blaster Live!, X-Fi, and Audigy series and the Hercules Digifire 7.1, Game Theater XP 7.1, and Fortissimo III 7.1 support digital-input speaker systems. Depending on which types of speakers you are using and how they are attached, you might need to switch your mixer settings in Windows from analog to digital to hear sounds from your applications.

To learn more about speaker terminology and how to ensure your speaker configuration is correct, see the section "[Speakers](#)," later in this chapter.

Voice Dictation and Control

Voice dictation and voice control are a long-time dream of computer users, but unlike science-fiction movies in which the computer always understands the speaker, real-life applications for voice interfacing to computers haven't always been satisfying in practice.

Current vendors of voice-dictation software available in English include

- *ScanSoft.* Dragon NaturallySpeaking; IBM ViaVoice (www.nuance.com/)
- *Microsoft.* Microsoft Office XP and 2003 (www.microsoft.com)

Although the number of vendors of voice-dictation and control software is smaller than it was a few years ago, results are getting better, particularly if you

- Take time to train the software adequately.
- Use a computer with a 1GHz or faster processor and 256MB of RAM or greater.
- Use a microphone designed for speech recognition, preferably one that the software designer recommends.

Note

You can find an excellent summary of the current state of voice recognition, links to products and articles, as well as historical information at Itamar Even-Zohar's Page on Speech Recognition (<http://www.tau.ac.il/~itamarez/sr/index.html>).

For more information about voice recognition, see "Voice Dictation Software" in [Chapter 20](#) of *Upgrading and Repairing PCs, 12th Edition*, included on the disc accompanying this book.

Sound Producers

Sound producers are people who intend to create their own sound files. These can range from casual business users recording low-fidelity voice annotations to professional musicians and MIDI maniacs. These users need an adapter that can perform as much of the audio processing as possible itself, so as not to place an additional burden on the system processor. Adapters that use DSPs to perform compression and other tasks are highly recommended in this case. Musicians will certainly want an adapter with as many voices as possible and a wavetable synthesizer. Adapters with expandable memory arrays and the capability to create and modify custom wavetables are also preferable.

Many of the best sound cards for hardcore gamers also are suitable for sound producers by adding the appropriate sound-editing programs, such as Sound Forge, and by equipping the card with the appropriate connectors for SPDIF digital audio and MIDI interfaces. The Sound Blaster Audigy 2 ZS Platinum and Platinum Pro include internal (Platinum) and external (Platinum Pro) breakout boxes with these features. The Creative Labs Audigy 2 NX and other USB devices with 24-bit/96KHz sampling provide features similar to those found on the Audigy 2 ZS Platinum series, but can be added to any system with a USB port. Creative's latest card, the Sound Blaster X-Fi Elite Pro, is the next step and is a great sound card for sound producers. Capable of recording at 96KHz and with playback at up to 192KHz, the card includes three usage modes that allow you to customize your experience:

- *Creation mode*. This is ideal for music recording and creation.
- *Gaming mode*. This mode optimizes gaming performance and realism
- *Entertainment mode*. This is configured specifically for listening to music and watching movies.

Most other audio cards designed for sound production features add jacks to the traditional trio of connectors on the rear card bracket.

Playing and Creating Digitized Sound Files

You can use two basic types of files to store audio on your PC. One type is generically called a sound file and uses formats such as WAV, VOC, AU, and AIFF. Sound files contain waveform data, which means they are analog audio recordings that have been digitized for storage on a computer. Just as you can store graphic images at different resolutions, you can have sound files that use various resolutions, trading off sound quality for file size. The default sound resolution levels used by the Windows Sound Recorder are shown in [Table 14.3](#).

Table 14.3. Windows Default Sound File Resolutions

Format	Resolution	Frequency	Bandwidth	File Size
PCM	Telephone quality	11025Hz	8-bit mono	11KBps
	Radio quality	22050Hz	8-bit mono	22KBps
	CD quality	44100Hz	16-bit stereo	172KBps

If you have a sound card that supports DVD-quality (48000Hz, 16-bit stereo, 187KBps), you can also save sounds at that frequency with the Windows Sound Recorder, but you must select that setting manually. Note that the Windows Sound Recorder applet uses the Pulse Code Modulation (PCM) method for storing sounds as its default. PCM produces the highest quality of sound, but because it doesn't use any type of data compression, file sizes can be enormous.

Note

When you use the Windows Sound Recorder, you can reduce the size of the audio files you create by choosing a different format and sampling frequency and selecting stereo or mono recording. If you want to experiment with the results of various formats, save the audio at the highest quality setting using PCM, retrieve the original audio file, change one or more settings, and save the changes under a different name.

As you can see from [Table 14.3](#), the difference in file sizes between the highest and lowest audio resolution levels is substantial. CD-quality sound files can occupy enormous amounts of disk space. At this rate, just 60 seconds of audio would require more than 10MB of storage. For applications that don't require or benefit from such high resolution, such as voice annotation, telephone-quality audio is sufficient and generates much smaller files. To achieve a balance between high quality and smaller file sizes, you can convert conventional WAV files into compressed formats, such as MP3 or WMA audio files.

The other type of file is a MIDI file, which consists of a musical score that is played back by synthesized or sampled musical instruments incorporated into the sound card's MIDI support.

Note

To learn more about the differences between MP3, WMA, and MIDI files, see "Audio Compression and MIDI Files" in the Technical Reference located on the disc packaged with this book.

On a multimedia PC, it is often possible for two or more sound sources to require the services of the audio adapter at the same time. Any time you have multiple sound sources you want to play through a single set of speakers, a mixer is necessary.

Most audio adapters include a mixer that enables all the different audio sources, MIDI, WAV, line in, and CD to use the single line-out jack. Starting with Windows 95 through the latest Windows versions (XP Pro/XP Home), Windows uses a single mixer for both recording and playback features, instead of using separate mixers as with Windows 3.x. Normally, the adapter ships with software that displays visual sliders like you would see on an actual audio mixer in a recording studio. With these controls, you can set the relative volume of each of the sound sources.

Tip

Whenever you change from analog to digital speakers or add speakers to a two-speaker configuration, you must adjust the mixer controls to match your current speaker configuration. If you don't, you will be unable to hear anything through your speakers.

Audio Adapter Concepts and Terms

To fully understand audio adapters and their functions, you need to understand various concepts and terms. Terms such as 16-bit, CD quality, and MIDI port are just a few. Concepts such as sampling and digital-to-audio conversion (DAC) are often sprinkled throughout stories about new sound products. You've already learned about some of these terms and concepts; the following sections describe many others.

The Nature of Sound

To understand an audio adapter, you must understand the nature of sound. Every sound is produced by vibrations that compress air or other substances. These sound waves travel in all directions, expanding in balloon-like fashion from the source of the sound. When these waves reach your ear, they cause vibrations that you perceive as sound.

Two of the basic properties of any sound are its pitch and intensity.

Pitch is the rate at which vibrations are produced. It is measured in the number of hertz (Hz), or cycles per second. One cycle is a complete vibration back and forth. The number of Hz is the frequency of the tone; the higher the frequency, the higher the pitch.

Humans can't hear all possible frequencies. Very few people can hear sounds with frequencies less than 16Hz or greater than about 20KHz (kilohertz; 1KHz equals 1000Hz). In fact, the lowest note on a piano has a frequency of 27Hz, and the highest note has a frequency a little higher than 4KHz. Frequency-modulation (FM) radio stations can broadcast notes with frequencies as high as 15KHz.

The amazing compression ratios possible with MP3 files, compared to regular CD-quality WAV files, is due in part to the discarding of sound frequencies that are higher or lower than normal hearing range during the ripping process.

The intensity of a sound is called its *amplitude*. This intensity determines the sound's volume and depends on the strength of the vibrations producing the sound. A piano string, for example, vibrates gently when the key is struck softly. The string swings back and forth in a narrow arc, and the tone it sends out is soft. If the key is struck more forcefully, however, the string swings back and forth in a wider arc, producing a greater amplitude and a greater volume. The loudness of sounds is measured in decibels (db). The rustle of leaves is rated at 20db, average street noise at 70db, and nearby thunder at 120db.

Evaluating the Quality of Your Audio Adapter

The quality of an audio adapter is often measured by three criteria: frequency response (or range), total harmonic distortion, and signal-to-noise ratio.

The *frequency response* of an audio adapter is the range in which an audio system can record or play at a constant and audible amplitude level. Many cards support 30Hz20KHz. The wider the spread, the better the adapter.

The *total harmonic distortion* measures an audio adapter's linearity and the straightness of a frequency response curve. In layman's terms, the harmonic distortion is a measure of accurate sound reproduction.

Any nonlinear elements cause distortion in the form of harmonics. The smaller the percentage of distortion, the better. This harmonic distortion factor might make the difference between cards that use the same audio chipset. Cards with cheaper components might have greater distortion, making them produce poorer-quality sound.

The *signal-to-noise ratio* (*S/N* or *SNR*) measures the strength of the sound signal relative to background noise (hiss). The higher the number (measured in decibels), the better the sound quality. For example, the top-of-the-line Sound Blaster X-Fi Elite Pro delivers pristine 136dB SNR audio playback quality as compared to the Audigy 2 sound card (106db) or the older Sound Blaster Audigy (100db) and AWE64 (90db).

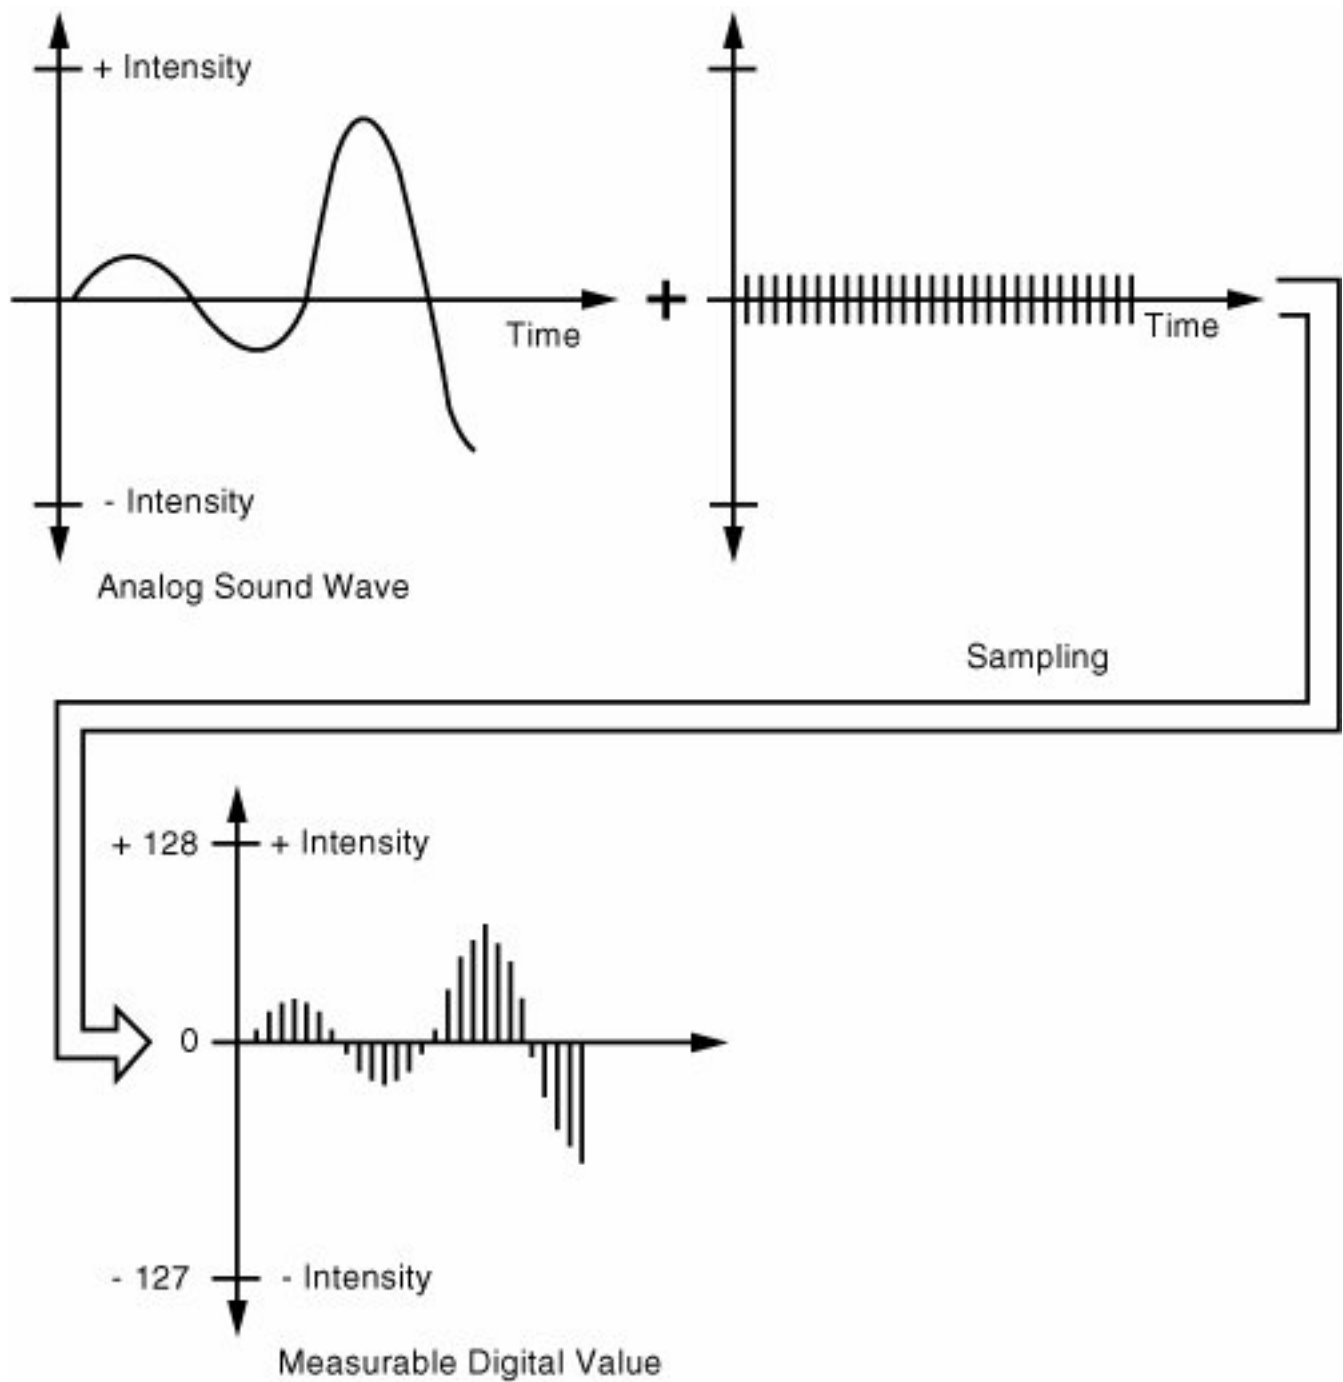

These factors affect all types of audio adapter use, from WAV file playback to speech recognition. Keep in mind that low-quality microphones and speakers can degrade the performance of a high-quality sound card.

Sampling

With an audio adapter, a PC can record waveform audio. Waveform audio (also known as sampled or digitized sound) uses the PC as a recording device (like a tape recorder). Small computer chips built into the adapter, called analog-to-digital converters (ADCs), convert analog sound waves into digital bits that the computer can understand. Likewise, digital-to-analog converters (DACs) convert the recorded sounds to an audible analog format.

Sampling is the process of turning the original analog sound waves into digital (binary) signals that the computer can save and later replay (see [Figure 14.7](#)). The system samples the sound by taking snapshots of its frequency and amplitude at regular intervals. For example, at time X the sound might be measured with an amplitude of Y. The higher (or more frequent) the sample rate, the more accurately the digital sound replicates its real-life source and the larger the amount of disk space needed to store it.

Figure 14.7. Sampling turns a changing sound wave into measurable digital values.

Originally, sound cards used 8-bit digital sampling that provided for only 256 values (2^8), which could be used to convert a sound. More recently, sound cards have increased the quality of digitized sound by using 16-bit (2^{16}) sampling to produce 65,536 distinct values. Today's highest-quality sound cards feature 24-bit sampling (2^{24}), which translates into more than 14.8 million possible digital values that can be matched to a given sound.

Note

For more information on the differences between 8-bit and 16-bit audio sampling, see "8-Bit Versus 16-Bit," in [Chapter 16](#) of *Upgrading and Repairing PCs, 13th Edition*, included on the disc accompanying this book.

You can experiment with the effects of various sampling rates (and compression technologies) by recording sound with the Windows Sound Recorder or a third-party application set to CD-quality sound. Save the sound and play it back at that highest-quality setting. Then convert the file to a lower-quality setting, and save the sound file again with a different name. Play back the various versions, and determine the lowest quality (and smallest file size) you can use without serious degradation to sound quality.

Who's Who in Audio

Because audio adapters have become common features in systems, many vendors have produced audio adapters, audio chips, integrated motherboard chipsets with audio features, and even specialized vacuum tube audio. This section examines some of these companies and their products.

As you've learned in other chapters, I believe it is very important to get all the technical information you can about your computer and its components. By knowing who makes the audio chip your computer depends on, you can find out what the hardware can do and be better able to find upgrades to the software drivers you need to get the most out of your audio hardware.

Chipset Makers Who Make Their Own Audio Adapters

Just as graphics card vendors are divided into two camps, chipset makers are divided into these two categories:

- Card and device makers who produce their own chipsets
- Card and device makers who use chipsets from other vendors

Audio adapter vendors fall into the same categories. One of the pioneers of the audio adapter business, Creative (formerly known as Creative Labs), has also been among the leaders in developing audio chips. Creative develops audio chips primarily for its own Sound Blasterbranded products, but it has sold some of its older Sound Blaster 16 products into OEM markets.

Creative's major audio chips have included the following:

- *Vibra-16*. This was used in the later Sound Blaster 16 cards; it doesn't support wavetable or 3D effects.
- *Ensoniq ES137x series (ES1370/71/73)*. These were used in the Sound Blaster PCI64 and PCI 128 series as well as the Ensoniq Audio PCI and Vibra PCI series. They support soft wavetable features, four speakers on some models and Microsoft Direct 3D but don't support 3D acceleration or EAX positional audio.
- *EMU-8000*. This audio chip was used by the AWE32/64 series and features 32-voice wavetable synthesis but no 3D acceleration. The AWE64 used software to generate 32 additional voices for a total of 64 voices.
- *EMU10K1*. This audio chip was at the heart of the Live! and Live 5.1 series sound cards as well as the PCI 512; it features 3D acceleration, EAX positional audio for one audio stream, a reprogrammable DSP, and soft wavetable support.
- *EMU10K2 (also known as Audigy)*. This is the audio chip at the heart of Creative Labs' Sound Blaster Audigy series sound cards; it features 3D acceleration, EAX HD positional audio for up to four audio streams, a reprogrammable DSP, and soft wavetable support. This chip supports professional-level 24-bit sampling at 96KHz and real-time sampling at Dolby Digitalquality 24-bit samples at 48KHz.
- *CA0102 (also known as Audigy 2)*. This audio chip is the one used by the Creative Labs Audigy 2 series. It's a development of the EMU10K2 chip, adding support for 24-bit 96KHz output, Dolby Digital EX 6.1 decoding and 6.1 sound in DirectX games, and 64 hardware polyphonic voices.
- *CA0185*. This audio chip is used by the Sound Blaster MP3+. It features 2.1 audio support for analog and digital speakers, 48KHz/16-bit playback and recording, and 3D acceleration.
- *CA0186*. This audio chip is used by the Audigy 2 NX. It features Dolby Digital EX 7.1 decoding, 7.1 sound in DirectX games, 96KHz/24-bit stereo output, and 3D audio acceleration.

- *CA0102-ICT (also known as Audigy 2 ZS)*. This audio chip is used by the Creative Labs Audigy 2 ZS series. It's a development of the CA0102 chip, adding support for Dolby Digital EX 7.1 decoding, Dolby ETS decoding, 7.1 sound in DirectX games, and 192KHz/24-bit stereo output.
- *Extreme Fidelity (X-Fi)*. This is the chip used in Creative's new X-Fi line of sound cards. The Creative X-Fi Xtreme Fidelity audio processor has over 51 million transistors capable of handling more than 10,000 MIPS. This is 24 times more powerful than its predecessor, the Sound Blaster Audigy 2 ZS.

Various other companies have produced their own sound chips in the past but no longer do so. The primary makers that fit in this category are

- *Aureal*. Its A3D technology was regarded by many as superior to Creative Labs' original EAX 3D positional audio, but the company was absorbed by Creative Labs in mid-2000. Because Creative's new EAX HD is superior to A3D, there will be no further development of this technology.
- *Yamaha*. Its OPL2 and OPL3 chips were among the best FM-synthesis chips used on older sound cards, and its MIDI performance in later models was outstanding. However, its emphasis is now on MIDI daughtercards and professional sound-recording cards such as the SW1000XG. Some of its retail and OEM products might still be available, though.
- *Philips*. Its ThunderBird Q3D (SAA7780) and ThunderBird Avenger (SAA7785) chips, jointly developed with QSound Labs, provided high-quality 3D acceleration for Philips's now-discontinued line of PCI-based sound cards. Some third-party sound cards also used the SAA7780 chip, but the six-channel SAA7785 was used only by Philips. See [Table 14.4](#) for details.

Table 14.4. Philips ThunderBird Audio Chips

Audio Chip	Sound Cards	3D Audio	Speaker Support	Other Features
ThunderBird Q3D (SAA7780)	Philips PSC702, PSC704; Aztech PCI-368DSP; I/O Magic MagicQuad 8; Labway Thunder	64 3D hardware streams; EAX and QSound	4.1	DOS Sound 3D Blaster emulation; wavetable MIDI
ThunderBird Avenger (SAA7785)	Philips PSC604, PSC605, PSC703, PSC705, PSC706	96 3D hardware streams; EAX and QSound	Dolby Digital 5.1	DOS Sound Blaster emulation; wavetable MIDI

Should you panic if your favorite audio adapter is an "orphan?" Not necessarily. If the audio adapter vendor provides good technical support and up-to-date drivers, you're okay for now. But, the next time an operating system update or new audio API shows up, you probably won't be able to take advantage of it unless you replace your audio adapter.

Major Sound Chip Makers

Most companies other than Creative depend on third parties to make their audio chips. Some of the major vendors include Aztech; Cirrus Logic/Crystal Semiconductor; ESS Technology; C-Media Electronics; ForteMedia, Inc.; and VIA Technologies.

Discontinued and Orphan Sound Chips and Sound Card Producers

The following sound chips are no longer being sold, and ongoing support is limited or no longer available. If you use an audio adapter based on one of these products, you might need to upgrade if you can't get drivers for new and forthcoming operating systems.

Discontinued products include

- *Oak Technology OTI-601 series*. Oak left the audio chipset business in early 1998.
- *Trident 4DWave-NX series*. This 3D audio chipset was used on some cards from smaller audio adapter vendors, such as Aztech, Jaton, and Hoontech.

Note

The former Diamond Multimedia division of S3 (later Sonic Blue, now out of business) sold sound cards using chips from various vendors, including ESS Technology, Aureala, and others. The current Diamond Multimedia product line of graphics cards and modems is sold and supported by Best Data Products.

Motherboard Chipsets with Integrated Audio

The Intel 810 chipset was the first mainstream chipset for a major CPU to integrate audio; it works with Celeron CPUs. Its inspiration might have been the Cyrix/National Semiconductor Media GX series, which used a trio of chips to substitute for the CPU, VGA video, onboard audio, memory, and I/O tasks.

Thanks to improvements in chipset design and faster CPU performance, today's best integrated chipsets can provide solid mid-range performance. Almost all recent chipsets from Intel, VIA, ALi, and SiS have integrated audio (see [Chapter 4](#), "Motherboards and Buses," for details). In almost every case, integrated audio supports the AC'97 audio standard.

AC'97 Integrated Audio

The phrase *AC'97 integrated audio* can be found in the descriptions of most recent systems. Because AC'97 can replace the need for a separate audio card but might not be a satisfactory replacement, you need to understand what it is and how it works.

AC'97 (often referred to as AC97) is an Intel specification that connects an audio codec (compression/decompression) architecture to a section of a South Bridge, an I/O Communications Hub chip called the AC-Link control, or an audio controller such as the VIA Envy24 series. The AC-Link control works with the CPU and an AC'97 digital signal processor (DSP) to create audio.

The AC'97 audio codec could be a physical chip on the motherboard, a chip on a small daughterboard called a *communications and networking riser (CNR)*, or a software program. Thus, a motherboard with AC'97 integrated sound support doesn't require the use of a separate audio card for sound playback. Sometimes AC'97 is also used to refer to audio chips on a sound card, but in this discussion we will use it to refer only to integrated audio. Sometimes motherboards also integrate an analog modem through an MC '97 codec chip, or they might have an AMC '97 (audio/modem) codec chip to combine both functions.

Note

Some low-cost sound cards and some USB-based audio products use AC'97 codec chips along with additional components instead of traditional single-chip audio solutions.

It's important to realize that, although most recent chipsets support AC'97 audio, this does not mean that every motherboard built on a particular chipset uses the same AC'97 codec, or even the same method of creating sound. In most cases, AC'97 is implemented through a small AC'97 codec chip on the motherboard (see [Figure 14.8](#)). It can be surface-mounted as shown in [Figure 14.8](#), but many vendors use a small socket instead.

Figure 14.8. The VIA VT1612A is a typical AC'97 2.2compliant codec chip. *Photo courtesy of VIA Technologies, Inc.*

A few motherboards use an AMR or a CNR riser card to implement AC'97 audio along with audio ports.

For various reasons, including audio codec features and price, different motherboard vendors might use different AC'97 codec chips on motherboards that use the same chipset.

For example, compare the following motherboards based on the Intel 865PE chipsets as listed in [Table 14.5](#).

Table 14.5. Sample AC'97 Codecs Used with Intel 865Based Motherboards

Vendor	Motherboard Model	AC'97 Codec Chip
--------	-------------------	------------------

FIC	P4-865PE Max II	Analog Devices AD1980
Soyo	Sy-P4I865PE Plus Dragon 2	C-Media 9739A
Giga-Byte	GA-8IPE1000-G	Realtek ALC850

Major vendors of AC'97 codecs include Analog Devices (SoundMAX), C-Media, Cirrus Logic (Crystal Audio), National Semiconductor, Realtek (includes former Avance Logic products), SigmaTel (STAC C-Major), VIA Technologies, and Wolfson Microelectronics plc.

Note

The drivers for a particular AC'97 codec chip are supplied by your motherboard vendor because they must be customized to the combination of codec and South Bridge/ICH chip your motherboard uses.

Although the AC'97 specification recommends a standard pinout, differences do exist between AC'97 codec chips. Some vendors of AC'97 chips provide technical information to help motherboard builders design sockets that can be used with different models of the AC'97 codec chip. However, in other cases, AC'97 codecs are surface-mounted to the motherboard.

The four versions of the AC'97 codec are as follows:

- *AC'97 1.0.* Has fixed 48KHz sampling rate and stereo output
- *AC'97 2.1.* Has options for variable sampling rate and multichannel output
- *AC'97 2.2.* Has AC'97 2.1 features plus optional S/PDIF digital audio and enhanced riser card support; released in September 2000
- *AC'97 2.3.* Has AC'97 2.1/2.2 features plus support for true Plug and Play detection of audio devices; released in July 2002

Note

Intel released Intel High Definition Audio in 2004 for delivering high-definition audio capable of playing back more channels at higher quality than AC'97 integrated audio formats. The hardware based on Intel HD Audio specifications is capable of delivering 192KHz/32-bit quality for eight channels.

Note

Audio solutions that use AC'97 2.3compliant codecs can detect whether you have connected a speaker to the microphone jack or a microphone to the speaker jack and warn you that the wrong jack is being used for the device. This helps eliminate one of the most common causes of audio failures.

Most recent motherboards with integrated audio support AC'97 2.2 or 2.3. To learn more about the AC'97 specifications, see the Intel Research and Development, Audio Codec site at www.intel.com/design/chipsets/audio/.

To determine whether a particular motherboard's implementation of AC'97 audio will be satisfactory, follow these steps:

1.

Determine which codec chip the motherboard uses. Read the motherboard manual or see which driver the motherboard uses for audio.

2.

Look up the chip's features and specifications. If you are not sure of the chip manufacturer, look up the part number with a search engine such as Google.

3.

Use a search engine to find reviews of the chip's sound quality and performance (typically found as part of a motherboard review).

4.

Look at the motherboard's features to determine whether it uses the full capabilities of the codec chip. Chips that support AC'97 2.1 can offer up to six-channel analog audio; those that support AC'97 2.2 can also offer S/PDIF digital audio. However, motherboard makers don't always provide the proper outputs.

5.

Analyze how you use audio. If you play a lot of 3D games, you're not likely to be satisfied with the performance of any integrated audio solution, no matter what its features might be. You can disable onboard audio with a BIOS setting if you prefer to install your own audio card.

For details on how to enable and disable onboard audio, see "[Peripheral Configuration](#)," p. [451](#).

A Open TubeSound

The Taiwan-based motherboard maker AOpen, part of the Acer Group, came up with a very interesting gimmick in June 2002 when it introduced the world's first PC motherboard with a vacuum tubebased audio amplifierthe AOpen AX4B-533 Tube. Although, the motherboard, which was based on the Intel 845E chipset and uses a Realtek ALC650 AC'97 audio codec chip, is no longer a current product, its unique design is still worth noting here. At first, many PC users wondered whether this was an April Fool's joke that showed up late. Why a vacuum tube? AOpen engineers pointed out that serious audio-philes have continued to use

vacuum-tube amplifiers because of their rich sound. They felt that audio-philes would pay a premium price for similar technology in the sound circuitry of a PC. AOpen used the following design features to bring the vacuum tube into the twenty-first century:

- *A switching mode power supply to provide adequate tube power.* Tubes fell out of favor in the late 1950s because they require more power than transistors and integrated circuits.
- *A dual-triode.* This design has one tube with two front stereo channels and is modeled after the design used by classic pre-amp circuits, which can also accept input from standard sound cards.
- *Frequency isolation wall (FIW) noise reduction.* This shields the tube circuitry from the normal EMI/RFI interference inside the computer.
- *High mean time between failure (MTBF) design for motherboard and tube circuitry.*

The additional circuitry used by the AX4B-533 Tube made it one of the most expensive motherboards using the 845E chipset (see [Figure 14.9](#)). However, it has received rave reviews from many computer publications and users for audio quality, performance, and (not least) the snob appeal of having the first motherboard on the block like it.

Figure 14.9. A close look at the A4XB-533's vacuum tube sound system.

The AX4B-533 Tube's audio quality is optimized for classical and jazz music listening. AOpen has now released additional vacuum-tube-based motherboards: the AX4GE Tube and AX4PE Tube for Pentium 4 processors and the AK79G Tube for Athlon XP processors. These motherboards are optimized for rock and pop music thanks to a slightly revised tube and amplifier design.

Tip

To compare these motherboards in more detail, see the AOpen TubeSound technology website at <http://usa.aopen.com/tech/techinside/Tube.htm>.

3D Audio

One of the biggest issues for serious game players when audio adapters are considered is how well they perform 3D audio tasks. This has been complicated by several factors, including the following:

- Differing standards for positional audio
- Hardware versus software processing of 3D audio
- DirectX support issues

Positional Audio

The underlying issue common to all 3D sound cards is that of positional audio, which refers to adjusting features such as reverberation; balance; and apparent sound "location" to produce the illusion of sound coming from in front of, beside, or even behind the user. One very important element in positional audio is HRTF (Head Related Transfer Function), which refers to how the shape of the ear and the angle of the listener's head changes the perception of sound. Because HRTF factors mean that a "realistic" sound at one listener's head angle might sound artificial when the listener turns to one side or the other, the addition of multiple speakers that "surround" the user, as well as sophisticated sound algorithms that add controlled reverberation to the mix, are making computer-based sound more and more realistic.

Creative Labs' Environmental Audio Extensions (EAX) has become the de facto standard for 3D audio since the demise of Aureal's A3D in mid-2000. There are five versions of EAX:

- EAX 1.0
- EAX 2.0
- EAX Advanced HD (also known as EAX 3.0)
- EAX 4.0 Advanced HD
- EAX 5.0 Advanced HD

EAX 1.0 introduced 26 presets designed to simulate the audio effects caused by typical building and natural environments along with the capability to adjust volume, reverberation, decay time, and damping. EAX 2.0 adds occlusions (how sound originating in one room is heard in another room) and obstructions (how sound is heard when an object blocks direct sound waves and only reflections can be heard).

EAX 1.0 and EAX 2.0 are supported both by Creative's Sound Blaster and Audigy series of sound cards but also by most recent third-party sound cards and integrated audio solutions, thanks to Creative's release of these standards to the industry.

EAX Advanced HD, introduced by the Sound Blaster Audigy, adds support for multienvironmenteach sound (up to four) can have its own environmental effects. It also adds environment morphing, environment panning, and environment reflection, three methods used to change environment sounds as the player moves through the game. Environmental filtering fine-tunes how sounds change from environment to environment. Audigy 2's version of EAX Advanced HD adds the capability to convert DirectX 3D audio (Direct3D) into 6.1 audio on systems with 6.1 speaker systems. EAX Advanced HD supports up to 32 channels of Direct 3D hardware voice acceleration.

EAX 4.0 Advanced HD, introduced by the Sound Blaster Audigy 2 ZS and also used with the Audigy 4, adds sound effects such as pitch and frequency shifting, automatic gain control compression, a wah-wah pedal, chorus, distortion, a whooshing effect (flanger), and a ring modulator. EAX 4.0 Advanced HD also adds a comb filter to remove audio artifacts, HRTF filters, cross-talk cancellation algorithms that support speaker types from headphones (2.0) up through 7.1, and 64 channels of Direct 3D hardware voice acceleration.

Sound Blaster introduced EAX 5.0 Advanced HD to exploit the full potential of the Creative X-Fi Xtreme Fidelity Audio Processor. It delivers double the voice count, giving you more detail and speed in your games and letting developers more easily add interactive music to games. EAX Advanced HD 5.0 adds a dedicated bass feed for each of the 128 voices, so gaming audio becomes more cinematic. A feature called Environment FlexiFX gives developers the freedom to use any of four simultaneous effects with any of the 128 voices.

Note

Audigy 2 cards (but not the low-end Audigy LS) can also use EAX 4.0 Advanced HD through a driver update.

The major alternative to EAX is Sensaura's 3D positional audio technology (3DPA). Most third-party sound cards support Sensaura 3DPA along with EAX 1.0/2.0. The full range of Sensaura 3DPA features include

- *Digital Ear*. HRTF filters.
- *Virtual Ear*. Customizes Digital Ear for the listener's ear size and positioning.
- *MacroFX*. Improves realism of close sound sources, such as a buzzing insect.
- *ZoomFX*. Improves realism of sounds from different sizes of objects, such as trains versus motorcycles.
- *EnvironmentFX*. Preset environments with adjustable properties.
- *XTC and MultiDrive*. Crosstalk cancellation for speaker systems up to 7.1.
- *Headphone Theater*. Simulates 5.1 audio for headset users.
- *GameCODA audio middleware*. Developed using Sensaura's core suite of technologies, it empowers PC, PlayStation 2, Xbox, and Nintendo Game Cube developers to easily integrate high-quality audio into their game titles.

Note

Some audio cards that use Sensaura 3DPDA technology might not support all the features, or they might require a software upgrade. Contact your audio card or motherboard vendor for details.

3D Audio Processing

A second important issue for game players is how the sound cards produce 3D audio. As with 3D video, there are two major methods:

- Host-based processing (which uses the CPU to process 3D, which can slow down overall system operation)

- Processing on the audio adapter (referred to as 3D acceleration)

Some 3D audio cards perform some or all of the processing necessary for 3D using the host's CPU, whereas others use a powerful DSP that performs the processing on the audio adapter itself. Cards that use host-based processing for 3D audio as well as systems that use AC'97 audio codecs for integrated 3D audio can cause major drops in frame rate (frames per second of animation displayed onscreen by a 3D game) when 3D sound is enabled on systems with processors running at speeds under 1GHz. However, cards with their own 3D audio processors onboard have little change in frame rate whether 3D sound is enabled or disabled. Many of the latest chips from major audio adapter and chipset vendors support 3D acceleration, but the number of 3D audio streams supported varies greatly by chip and it can sometimes be limited by problems with software drivers.

A good rule of thumb for realistic gaming is to have an overall average frame rate of at least 30fps (frames per second). With CPUs running at 1GHz or above, this is easy to achieve with any recent 3D audio card or recent onboard integrated audio solutions. However, gamers using older CPUs, such as those running slower than 1GHz, will find that cards using the host CPU for some of the 3D processing will have frame rates that fall below the desired average of 30fps, making for clumsy gameplay. To see the effect of enabling 3D sound on the speed of popular games, you can use the built-in frame-rate tracking feature found in many games or check online game-oriented hardware review sources, such as www.anandtech.com. Frame rates are closely related to CPU utilization; the more CPU attention your 3D audio card or integrated audio solution requires, the slower the frame rate will be.

As with 3D video, the main users of 3D sound are game developers, but business uses for ultra-realistic sound will no doubt follow.

DirectX Support Issues

The latest version of DirectX, DirectX 9.0c, is designed to give all sound cards with 3D support a major boost in performance compared to DirectX 8.x and earlier versions. Previous versions of DirectX supported 3D with DirectSound3D, but the performance of DirectSound3D was limited. Game programmers needed to test the audio adapter to see whether it supported DirectSound3D acceleration and then would either enable or disable 3D sounds based on the host hardware. Starting with DirectX 5.0, DirectSound3D works with third-party 3D acceleration features. Compared to DirectX 8.x, DirectX 9.0c improves 3D audio quality and performance. You can download it from the Microsoft DirectX website at www.microsoft.com/windows/directx.

Installing the Sound Card

Before you can install a sound card, you must open your computer. In almost all cases today, you will install a PCI audio adapter that supports Plug and Play configuration. Compared to the previous generation of ISA audio adapters, PCI audio adapters use fewer hardware resources, feature a lower CPU utilization rate, and provide better support for advanced 3D gaming APIs.

If you need to install an ISA audio adapter, see "Installing the Sound Card (Detailed Procedure)" in [Chapter 20](#) of *Upgrading and Repairing PCs, 11th Edition*, supplied in electronic form on the disc packaged with this book.

If your computer has integrated audio, in most cases you should disable it. You could have audio conflicts with AC'97 codec-based solutions and resource conflicts with solutions that emulate the Creative Labs Sound Blaster. Refer to [Chapter 5](#), "BIOS," for details.

If you have several empty bus slots from which to choose, install the audio adapter in the slot that is as far away as possible from the other cards in the computer. This reduces any possible electromagnetic interference; that is, it reduces stray radio signals from one card that might affect the sound card. The analog components on audio adapters are highly susceptible to interference, and even though they are shielded, they should be protected as well as is possible. Next, you must remove the screw that holds the metal cover over the empty expansion slot you've chosen. Remove your audio adapter from its protective packaging. When you open the bag, carefully grab the card by its metal bracket and edges. Do not touch any of the components on the card because any static electricity you might transmit can damage the card. Also, do not touch the gold-edge connectors. You might want to invest in a grounding wrist strap, which continually drains you of static build-up as you work on your computer.

Before you make your final decision about which slot to use for your audio adapter, take a careful look at the external cables you must attach to the card. Front and rear speakers, microphone, game controller, line in, S/PDIF, and other cables that attach to your system can interfere with (or be interfered by) existing cables already attached to your system. It's usually best to choose a slot that allows you to route the audio cables away from other cables. If you're installing a sound card that uses an internal 5 1/4" breakout box, be sure the ribbon cable from the drive bay used for the breakout box can comfortably reach the connector on the sound card. You might have to move a CD-ROM, CD-RW, or DVD drive to a different drive bay to free up a drive bay needed by the breakout box.

[Figure 14.10](#) shows a Creative Labs Audigy sound card after installation in a computer. The four-wire analog and two-wire digital cables to the CD-ROM drive are connected to the card, as is the ribbon cable to the Audigy Drive internal breakout box. However, the cable to the Audigy Drive's SB1394 (IEEE-1394a-compatible) port has not yet been connected to the card.

Figure 14.10. A Creative Labs Audigy sound card installed in a typical PC.

- | | |
|--|--------------------------------------|
| 1. Mounting screw | 5. SB1394 (IEEE-1394a) I/O connector |
| 2. TAD (telephone answering device) analog audio connector | 6. CD SPDIF digital audio cable |
| 3. CD audio analog cable | 7. Audigy Drive I/O cable |
| 4. Aux in analog audio connector | 8. Game port (joystick) header pins |

If your system has an internal CD-ROM drive with an analog audio cable, connect the audio cable to the adapter's CD Audio In connector, as shown in [Figure 14.10](#). This connector is a four-pin connector and is keyed so that you can't insert it improperly. Note that no true standard exists for this audio cable, so be sure you get the correct one that matches your drive and adapter. If you need to purchase one, you can find cables with multiple connectors designed for various brands of CD-ROM drives.

This will allow you to play music CDs through the sound card's speakers and to use analog ripping if you want to create MP3 files from your CDs.

Many recent CD-ROM and DVD drives also have a digital audio connector that supports a two-wire connector. Attach one end of the digital audio cable to the rear of the drive and the other end to the CD SPDIF or CD Digital Audio connector on the sound card (refer to [Figure 14.10](#)). This enables you to perform digital ripping if you want to create MP3 files from your CDs. Note that some ripping programs can also use digital signals received through the drive's data cable.

Next, insert the adapter's edge connector in the bus slot, but first touch a metal object, such as the inside of the computer's cover, to drain yourself of static electricity. When the card is firmly in place, attach the screw (refer to [Figure 14.10](#)) to hold the expansion card and then reassemble your computer.

Connecting PC Speakers and Completing the Installation

After the adapter card is installed, you can connect small speakers to the external speaker jack(s). Typically, sound cards provide 4 watts of power per channel to drive unpowered bookshelf speakers. If you are using speakers rated for less than 4 watts, do not turn up the volume on your sound card to the maximum; your speakers might burn out from the overload. You'll get better results if you plug your sound card into powered speakers—that is, speakers with built-in amplifiers. If your sound card supports a four-speaker system, check the documentation to see which jack is used for the front speakers and which for the rear speakers. To use the rear speakers for 3D audio, adjust the properties with the mixer control software supplied with your sound card.

Tip

If you have powered speakers but don't have batteries in them or have them connected to an AC adapter, don't turn on the speakers! Turning on the speakers without power will prevent you from hearing anything at all. Leave the speakers turned off and use the volume control built into your sound card's mixer software instead. Powered speakers sound better, but most small models can run without power in an emergency.

Some computer power supplies feature small jacks to provide power for computer speakers.

When the sound card installation is finished, you should have a speaker icon in the Windows System Tray. If the speaker icon (indicating the Volume Control) isn't visible, you can install it through the Control Panel's Add/Remove Programs icon. With Windows 9x/Me, select the Windows Setup tab and open the Multimedia section. Then, check the box labeled Volume Control. With Windows XP, open the Sounds and Audio Devices icon in Control Panel, click the Volume tab, and click the Place Volume icon in the taskbar box. In some cases you might be asked to insert the Windows CD-ROM if additional drivers are required to complete the installation.

If you use digital sound sources or output such as Dolby 5.1, CD digital, or S/PDIF, open the properties sheet for your mixer device and enable display of these volume controls.

Use the Volume Control to ensure your speakers are receiving a sound signal. The mixer sometimes defaults to Mute. You can usually adjust volume separately for wave (WAV) files, MIDI, microphone, and other components.

Using Your Stereo Instead of Speakers

Another alternative is to patch your sound card into your stereo system for greatly amplified sound and for support of advanced Dolby Digital sound for DVD playback. Check the plugs and jacks at both ends of the connection. Most stereos use pin plugs, also called RCA or phono plugs, for input. Although pin plugs are standard on some sound cards or breakout boxes, most use miniature 1/8" phono plugs, which require an adapter when connecting to your stereo system. For example, from Radio Shack you can purchase an audio cable that provides a stereo 1/8" miniplug on one end and phono plugs on the other. If you want to attach your sound card to Dolby 5.1 speakers, be sure you use cabling designed for the S/PDIF connectors on your sound card. Some might use RCA-type plugs, whereas others use an optical cable with a square end (also known as a Toslink connector).

Make sure that you get stereo not monoplugs, unless your sound card supports only mono. To ensure that you have enough cable to reach from the back of your PC to your stereo system, get a 6-ft. long cable.

Hooking up your stereo to an audio adapter is a matter of connecting the plugs into the proper jacks. If your audio adapter gives you a choice of output speaker/headphone and stereo line-out choose the stereo line-out jack for the connection. This will give you the best sound quality because the signals from the stereo line-out jack are not amplified. The amplification is best left to your stereo system. In some cases, you'll attach a special DIN plug to your audio adapter that has multiple connections to your stereo system.

Connect this cable output from your audio adapter to the auxiliary input of your stereo receiver, preamp, or integrated amplifier. If your stereo doesn't have an auxiliary input, other input options include in order of preference tuner, CD, or Tape 2. (Do not use phono inputs, however, because the level of the signals will be uneven.) You can connect the cable's single stereo miniplug to the sound card's stereo line-out jack, for example, and then connect the two RCA phono plugs to the stereo's Tape/VCR 2 Playback jacks.

The first time you use your audio adapter with a stereo system, turn down the volume on your receiver to prevent blown speakers. Barely turn up the volume control and then select the proper input (such as Tape/VCR 2) on your stereo receiver. Finally, start your PC. Never increase the volume to more than three-fourths of the way up. Any higher and the sound might become distorted.

Note

If your stereo speakers are not magnetically shielded, you might hear a lot of crackling if they are placed close to your computer. Try moving them away from the computer, or use magnetically shielded speakers.

Tricks for Using the Tape Monitor Circuit of Your Stereo

Your receiver might be equipped with something called a tape monitor. This outputs the sound coming from the tuner, tape, or CD to the tape-out port on the back; it then expects the sound to come back in on the tape-in port. These ports, in conjunction with the line-in and line-out ports on your audio adapter, enable you to play computer sound and the radio through the same set of speakers.

Here's how you do it:

1.

Turn off the tape monitor circuit on your receiver.

2.

Turn down all the controls on the sound card's mixer application.

3.

Connect the receiver's tape-out ports to the audio adapter's line-in port.

4.

Connect the audio adapter's line-out port to the receiver's tape-in ports.

5.

Turn on the receiver, select some music, and set the volume to a medium level.

6.

Turn on the tape monitor circuit.

7.

Slowly adjust the line-in and main-out sliders in the audio adapter's mixer application until the sound level is about the same as before.

8.

Disengage and re-engage the tape monitor circuit while adjusting the output of the audio adapter so that the sound level is the same regardless of whether the tape monitor circuit is engaged.

Start playing a WAV file.

10.

Slowly adjust up the volume slider for the WAV file in the audio adapter's mixer application until it plays at a level (slightly above or below the receiver) that is comfortable.

Now you can get sounds from your computer and the radio through the receiver's speakers.

Different connectors might be needed if you have digital surround speakers and newer PCI-based sound cards. Check your speakers and sound card before you start this project.

Troubleshooting Sound Card Problems

To operate, an audio adapter needs hardware resources, such as IRQ numbers, a base I/O address, and DMA channels that don't conflict with other devices. Most adapters come preconfigured to use the standard Sound Blaster resources that have come to be associated with audio adapters. However, problems occasionally arise even with Plug and Play adapters. Troubleshooting might mean that you have to change the settings used by your system BIOS for PnP devices, move the sound card to another slot, or even reconfigure the other devices in your computer. No one said life was fair.

Hardware (Resource) Conflicts

The most common problem for audio adapters (particularly if you still use ISA cards) is that they might conflict with other devices installed in your PC. You might notice that your audio adapter simply doesn't work (no sound effects or music), repeats the same sounds over and over, or causes your PC to freeze. This situation is called a device, or hardware, conflict. What are they fighting over? Mainly the same bus signal lines or channels (called resources) used for talking to your PC. The sources of conflict in audio adapter installations are generally threefold:

- *Interrupt Requests (IRQs)*. Hardware devices use IRQs to "interrupt" your PC's CPU and get its attention. PCI cards can share IRQs, but ISA cards and onboard legacy ports such as serial, parallel, and PS/2 mouse ports can't.
- *Direct Memory Access (DMA) channels*. DMA channels move information directly to your PC's memory, bypassing the system processor. DMA channels enable sound to play while your PC is doing other work. ISA sound cards and PCI sound cards emulating the Sound Blaster standard require DMA settings; PCI sound cards running in native mode don't use DMA channels.
- *Input/output (I/O) port addresses*. Your PC uses I/O port addresses to channel information between the hardware devices on your audio adapter and PC. The addresses usually mentioned in a sound card manual are the starting or base addresses. An audio adapter has several devices on it, and each one uses a range of addresses starting with a particular base address.

PCI-based sound cards and PCI-based onboard audio can share IRQs, don't use DMA channels (except when emulating a Sound Blaster card), and can use a wide variety of I/O port addresses. Consequently, resource conflicts involving PCI-based audio are extremely rare today, in part because systems no longer use ISA slots or ISA cards (ISA devices cannot share IRQs). However, if you still work with ISA sound cards or ISA or PCI cards that use game ports, you might encounter resource conflicts.

▶▶ See [Chapter 20](#) of *Upgrading and Repairing PCs, 12th Edition* on the disc accompanying this book for details on resolving conflicts involving ISA sound cards and game ports.

Other Sound Card and Onboard Audio Problems

Like the common cold, audio adapter problems have common symptoms. Use the following sections to diagnose your problem.

No Sound

If you don't hear anything from your audio adapter, consider these solutions:

- Make sure the audio adapter is set to use all default resources and that all other devices using these resources have been either reconfigured or removed if they cause a conflict. Use the Device Manager to determine this information.
- Are the speakers connected? Check that the speakers are plugged into the sound card's stereo line-out or speaker jack (not the line-in or microphone jack).
- Are the speakers receiving power? Check that the power "brick" or power cord is plugged in securely and that the speakers are turned on.
- Are the speakers stereo? Check that the plug inserted into the jack is a stereo plug, not mono.
- Are the mixer settings correct? Many audio adapters include a sound mixer application. The mixer controls the volume settings for various sound devices, such as the microphone or the CD player. There might be separate controls for both recording and playback. Increase the master volume or speaker volume when you are in the play mode.

If the Mute option is selected in your sound mixer software, you won't hear anything. Depending on the speaker type and sound source type, you might need to switch from analog to digital sound for some types of sound output. Make sure that the correct digital audio volume controls are enabled in your audio device's mixer control.

- Use your audio adapter's setup or diagnostic software to test and adjust the volume of the adapter. Such software usually includes sample sounds used to test the adapter.
- Turn off your computer for 1 minute and then turn it back on. A hard reset (as opposed to pressing the Reset button or pressing Ctrl+Alt+Delete) might clear the problem.
- If your computer game lacks sound, check that it is designed to work with your audio adapter. For example, some legacy (DOS-based) and early Windows games might require the exact settings of IRQ 7 (or IRQ 5), DMA 1, and I/O address 220 to be Sound Blaster compatible. You also might need to load DOS drivers to enable some recent sound cards to work with DOS games.
- If you're using motherboard-integrated audio, make sure the onboard audio is enabled (check the BIOS setup program) and that the proper drivers and player program have been installed (check the Windows Control Panel). With some motherboards, you might need to run a setup program on the motherboard driver CD to enable onboard sound.
- If you're using motherboard-integrated audio that uses a removable header cable (such as with many SDPIF optical or 4/6-channel analog speaker configurations), make sure the header cable is properly connected to the motherboard.

One-Sided Sound

If you hear sound coming from only one speaker, check out these possible causes:

- *Are you using a mono plug in the stereo jack?* A common mistake is to use a mono plug in the sound card's speaker or stereo-out jacks. Seen from the side, a stereo connector has two darker stripes. A mono connector has only one stripe.
- *If you're using amplified speakers, are they powered on?* Check the strength of the batteries or the AC adapter's connection to the electrical outlet. If each speaker is powered separately, be sure that both have working batteries.
- *Are the speakers wired correctly?* When possible, use keyed and color-coded connectors to avoid mistakes.
- *Is the audio adapter driver loaded?* Some sound cards provide only left-channel sound if the driver is not loaded correctly. Rerun your adapter's setup software or reinstall it in the operating system.
- *Are both speakers set to the same volume?* Some speakers use separate volume controls on each speaker. Balance them for best results. Separate speaker volume controls can be an advantage if one speaker must be farther away from the user than the other.
- *Is the speaker jack loose?* If you find that plugging your speaker into the jack properly doesn't produce sound but pulling the plug half-way out or "jimmying" it around in its hole can temporarily

correct the problem, you're on the road to a speaker jack failure. There's no easy solution; buy a new adapter or whip out your soldering iron and spend a lot more time on the test bench than most audio adapters are worth. To avoid damage to the speaker jack, be sure you insert the plug straight in, not at an angle.

Volume Is Low

If you can barely hear your sound card, try these solutions:

- *Are the speakers plugged into the proper jack?* Speakers require a higher level of drive signal than headphones. Again, adjust the volume level in your mixer application.
- *Are the mixer settings too low?* Again, adjust the volume level in your mixer application. If your mixer lets you choose between speakers and headphones, be sure to select the correct speaker configuration.
- *Is the initial volume too low?* If your audio adapter has an external thumbwheel volume control located on the card bracket, check to ensure that it is not turned down too low. Check the speakers' own volume controls as well.
- *Are the speakers too weak?* Some speakers might need more power than your audio adapter can produce. Try other speakers or put a stereo amplifier between your sound card and speakers.

Some Speakers Don't Play

If you can hear sound coming from some speakers, but not others, check the following:

- *Incorrect sound mixer settings.* Most systems assume that you are using two-channel (stereophonic) sound, even if you have plugged in four or more speakers. Select the correct speaker type with the Windows Speaker icon or a third-party sound mixer.
- *Additional speakers are connected to the wrong jacks.* Make sure you connect the additional speakers needed for four-channel or six-channel audio to the correct jacks. If you connect them to line-in or microphone jacks, they won't work.
- *Incorrect balance settings.* The volume control also adjusts the balance between the left and right speakers. If you hear audio from the left speakers only or the right speakers only, the balance control needs to be centered with the Windows Speaker icon or a third-party sound mixer.

Note

On some systems with integrated audio, audio jacks have multiple uses. For example, in six-channel mode on some systems, the normal line-in and microphone jacks might be reconfigured to work with rear and center/subwoofer speakers. In such cases, the mixer controls need to be reset.

Some Types of Sounds Play, But Others Don't

If you can hear CDs but not WAV or MP3 digital music, or can play WAV and MP3 but not CD or MIDI files, check the following:

- *Low volume or mute settings for some audio types.* Some audio mixers have separate volume controls for WAV/MP3, MIDI, CD digital, CD audio, and other sound types and sources. Unmute any

audio types you play back and adjust the volume as desired.

- *I/O port or DMA conflicts when playing DOS games.* On most ISA-based sound cards or PCI-based sound cards or integrated audio solutions, separate I/O port address ranges and DMA channels are used for MIDI, FM synthesis, and normal audio. A conflict can cause some types of sounds not to play.
- *Check the CD audio connection from your optical drive to your sound card.*

See [Chapter 20](#) of *Upgrading and Repairing PCs, 12th Edition* on the disc packaged with this book for details on resolving conflicts involving ISA sound cards and game ports.

Scratchy Sound

Scratchy or static-filled sound can be caused by several problems. Improving the sound can be as simple as rearranging your hardware components. The following list suggests possible solutions to the problem of scratchy sound:

- *Is your audio adapter near other expansion cards?* The adapter might be picking up electrical interference from other expansion cards inside the PC. Move the audio card to an expansion slot as far away as possible from other cards.
- *An ISA-based audio adapter requires a lot of CPU attention.* Frequent hard disk access can cause dropouts due to the CPUs switching between managing the sound card and the hard drive.
- *Are your speakers too close to your monitor?* The speakers can pick up electrical noise from your monitor. Move them farther away. Subwoofers should *never* be placed near the monitor because their powerful magnets can interfere with the picture. They should be on the floor to maximize low-frequency transmission.
- *Are you experiencing compatibility problems between particular games and your sound card?* If you notice sound problems such as stuttering voices and static on some games but not others, check with the game vendor for a software patch or with the sound card vendor for updated drivers. If the game uses DirectX, run the DXDIAG diagnostics program (select Start, Run; type **DXDIAG**; and click OK) and click the Sound tab. Adjust the slider for Hardware Sound Acceleration Level down one notch from Full (the default) to Standard, click Save All Information, and exit. Retry the game. If the problem persists, adjust the Hardware Sound Acceleration Level to Basic. If other games have performance problems after you adjust the Hardware Sound Acceleration Level, be sure to reset it to Full before playing those games.

Your Computer Won't Start

If your computer won't start at all, you might not have inserted the audio adapter completely into its slot. Turn off the PC and then press firmly on the card until it is seated correctly.

If you can't start your computer after installing a new sound card and its drivers, you can use the Windows "bootlog" feature to record every event during startup; this file records which hardware drivers are loaded during startup and indicates whether the file loaded successfully, didn't load successfully, or froze the computer. See the documentation for your version of Windows for details on how to create a bootlog when necessary.

Parity Errors or Other Lockups

Your computer might display a memory parity error message or simply crash. This is usually caused by

resource conflicts in one of the following areas:

- IRQ
- DMA
- I/O ports

If other devices in your system are using the same resources as your audio adapter, crashes, lockups, or parity errors can result. You must ensure that multiple devices in your system do not share these resources.

See [Chapter 20](#) of *Upgrading and Repairing PCs, 12th Edition* on the disc packaged with this book for details on resolving conflicts involving ISA sound cards and game ports.

Advanced Features

If you are having problems playing DVD audio, playing MP3 files, or using SPDIF connections, make sure that

- You have enabled the hardware resources on the sound card.
- You are using the correct playback program.
- Your mixer has the correct volume control setting for the device.
- Your cabling is correct for the device.

Other Problems

Sometimes sound problems can be difficult to solve. Due to quirks and problems with the way DMA is implemented in some motherboard chipsets, problems interacting with certain cards or drivers can occur. Sometimes altering the Chipset Setup options in your CMOS settings can resolve problems. These types of problems can take a lot of trial and error to solve.

The PC standard is based loosely on the cooperation among a handful of companies. Something as simple as one vendor's BIOS or motherboard design can make the standard nonstandard.

A good way to solve problems of all types with Plug and Play cards, a PnP BIOS, and a PnP operating system (Windows 9x/Me/2000/XP) is to use the Device Manager to remove the sound card, restart the system, and allow the card's components to be redetected. This installs a "fresh" copy of the software and reinserts Registry entries.

If you are using a motherboard with a VIA chipset, be sure to download and install the latest versions of VIA drivers.

Speakers

Successful business presentations, multimedia applications, and MIDI work demand external high-fidelity stereo speakers. Although you can use standard stereo speakers, they are often too big to fit on or near your desk. Smaller bookshelf speakers are better.

Sound cards offer little or none of the amplification needed to drive external speakers. Although some sound cards have small 4-watt amplifiers, they are not powerful enough to drive quality speakers. Also, conventional speakers sitting near your display can create magnetic interference, which can distort colors and objects onscreen or jumble the data recorded on nearby floppy disks or other magnetic media.

To solve these problems, computer speakers need to be small, efficient, and self-powered. Also, they should be provided with magnetic shielding, either in the form of added layers of insulation in the speaker cabinet or electronic cancellation of the magnetic distortion.

Caution

Although most computer speakers are magnetically shielded, do not leave recorded tapes, watches, credit cards, or floppy disks in front of the speakers for long periods of time.

Quality sound depends on quality speakers. A 16-bit audio adapter might provide better sound to computer speakers, but even an 8-bit adapter sounds good from a good speaker. Conversely, an inexpensive speaker makes both 8-bit and 16-bit adapter cards sound tinny.

Now dozens of models of PC speakers are on the market, ranging from inexpensive minispeakers from Sony, Creative, and LabTech to larger self-powered models from prestigious audio companies such as Bose, Cambridge Sound Works, Klipsch, Monsoon, and Altec Lansing. Many of the medium- to higher-end speaker systems even include subwoofers to provide additional bass response. To evaluate speakers, it helps to know the jargon. Speakers are measured by three criteria:

- *Frequency response.* A measurement of the range of high and low sounds a speaker can reproduce. The ideal range is 20Hz20KHz, the range of human hearing. No speaker system reproduces this range perfectly. In fact, few people hear sounds above 18KHz. An exceptional speaker might cover a range of 30Hz23000Hz, and lesser models might cover only 100Hz20000Hz. Frequency response is the most deceptive specification because identically rated speakers can sound completely different.
- *Total Harmonic Distortion (THD).* An expression of the amount of distortion or noise created by amplifying the signal. Simply put, distortion is the difference between the sound sent to the speaker and the sound you hear. The amount of distortion is measured in percentages. An acceptable level of distortion is less than .1% (one-tenth of 1%). For some CD-quality recording equipment, a common standard is .05%, but some speakers have a distortion of 10% or more. Headphones often have a distortion of about 2% or less.
- *Watts.* Usually stated as watts per channel, this is the amount of amplification available to drive the speakers. Check that the company means "per channel" (or RMS) and not total power. Many audio adapters have built-in amplifiers, providing up to 8 watts per channel (most provide 4 watts). This wattage is not enough to provide rich sound, however, which is why many speakers have built-in amplifiers. With the flick of a switch or the press of a button, these speakers amplify the signals they receive from the audio adapter. If you do not want to amplify the sound, you typically leave

the speaker switch set to "direct." In most cases, you'll want to amplify the signal.

Before purchasing a speaker set, be sure to do your research and look at some reviews to see what others think about the speakers you are considering. You can see CNET's speaker review and compare speakers side by side at http://reviews.cnet.com/4566-3179_7-0.html.

Inexpensive PC speakers sometimes use batteries to power the amplifiers. Because these speakers require so much power, you might want to invest in an AC adapter or purchase speakers that use AC power. With an AC adapter, you won't have to buy new batteries every few weeks. If your speakers didn't come with an AC adapter, you can pick one up from your local Radio Shack or hardware store. Be sure that the adapter you purchase matches your speakers in voltage and polarity; most third-party adapters are multiple voltage, featuring interchangeable tips and reversible polarity.

You can control the volume and other sound attributes of your speakers in various ways, depending on their complexity and cost. Typically, each speaker has a volume knob, although some share a single volume control. If one speaker is farther away than the other, you might want to adjust the volume accordingly. Many computer speakers include a dynamic bass boost (DBB) switch. This button provides a more powerful bass and clearer treble, regardless of the volume setting. Other speakers have separate bass and treble boost switches or a three-band equalizer to control low, middle, and high frequencies. When you rely on your audio adapter's power rather than your speakers' built-in amplifier, the volume and dynamic bass boost controls have no effect. Your speakers are at the mercy of the adapter's power.

For best audio quality, adjust the master volume on the sound card near the high end and use the volume control on powered speakers to adjust the volume. Otherwise, your speakers will try to amplify any distortions coming from the low-power input from the PC's audio adapter.

A 1/8" stereo minijack connects from the audio adapter's output jack to one of the speakers. The speaker then splits the signal and feeds through a separate cable from the first speaker to the second one (often referred to as the "satellite speaker").

Before purchasing a set of speakers, check that the cables between the speakers are long enough for your computer setup. For example, a tower case sitting alongside your desk might require longer speaker wires than a desktop computer.

Beware of speakers that have a tardy built-in sleep feature. Such speakers, which save electricity by turning themselves off when they are not in use, might have the annoying habit of clipping the first part of a sound after a period of inactivity.

Speakers that are USB based will not be capable of playing CD music unless the optical drive can perform digital audio extraction. Check your drive's specifications for information.

Headphones are an option when you can't afford a premium set of speakers. Headphones also provide privacy and enable you to play your PC audio as loud as you like.

For best results with newer sound cards that support four speakers or more, check the properties sheet for the audio adapter and set whether you're using headphones, stereo speakers, or a larger number of speakers.

Make sure that speakers are placed properly. If you use a subwoofer, put it on the floor for better bass sound and to reduce EMI interference with other devices.

How can you tell whether wireless satellite speakers are causing interference? Watch your monitor; frequencies as high as 2KHz can interfere with your video display. Move the speakers away from the monitor and check the display again.

Theater and Surround Sound Considerations

If you're a serious gamer or DVD movie lover, you won't be content with ordinary stereophonic sound. Most audio adapters now support front and rear speakers, and many of the best audio adapters also support Dolby-compatible 4.1 and 5.1 speaker setups.

To ensure you get the sound you expect from four or more speakers, check the following:

- *Use the properties sheet for your audio adapter to properly describe your speaker setup.* This includes selecting the number of speakers you are using, setting options for 3D environmental audio and positional sound such as reverb, and setting up your subwoofer if present.
- *Make sure you use the correct cabling between your speakers and audio adapter.* If you are planning to use AC3/Dolby speaker setups, such as 4.1, 5.1, 6.1, or 7.1, be sure you use the correct S/PDIF connection and configuration. This varies from audio adapter to audio adapter; check the vendor's website for details.
- *Make sure you have placed your speakers correctly.* In some cases you can adjust the audio adapter's properties to improve sound quality, but sometimes you might need to move the speakers themselves.
- *Make sure you have connected your speakers to the proper jacks.* Mixing up left and right or front and rear causes poor sound quality.

Typical Speaker Setups

The simplest audio configuration available today is stereo, which uses two speakers placed to overlap sound. Most audio adapters now support at least four speakers, but depending on the audio adapter, settings, and sound output options in the program, the rear speakers might simply mirror the front speakers' output, or you might have four distinct sound streams.

4-point surround sound uses four speakers plus a subwoofer to surround you with music and gaming sound effects; the four speakers are placed around the listener, and the subwoofer is usually placed near a wall or in the corner to amplify its low-frequency sound. The subwoofer in stereo or four-point surround sound setups is not on a separate circuit but is controlled by the same signals sent to the other speakers. A stereo speaker system with a subwoofer is often referred to as a *2.1 speaker configuration*, and a four-point surround sound configuration with a subwoofer is often referred to as a *4.1 speaker configuration*.

5.1 Surround sound, also referred to as Dolby Digital or DTS Surround sound, uses five speakers plus a subwoofer. The fifth speaker is placed between the front two speakers to fill in any missing sound caused by incorrect speaker placement. The subwoofer is independently controlled. This is the preferred sound system for use with DVD movies. Most lower-cost audio adapters lack support for 5.1 Surround sound.

Some of the latest sound cards support 6.1 and 7.1 Surround sound. The 6.1 configuration resembles the 5.1 Surround setup but adds a middle speaker along with a subwoofer. 7.1 Surround sound uses left-middle and right-middle speakers to flank the listener, along with a subwoofer. Depending on the sound card, some cards play back 5.1 or greater Surround sound configurations with analog speakers only, whereas others can also transmit Dolby Digital (AC-3), DTS Surround, or Dolby EX digital audio through the SPDIF digital audio port to a home theater system.

Microphones

Some audio adapters come complete with a microphone, but most do not. You'll need one to record your voice to a WAV file. Selecting a microphone is quite simple. You need one that has a 1/8" minijack to plug into your audio adapter's microphone, or audio in, jack. Most handheld microphones have an on/off switch. However, you can also use the Mute control in the audio mixer to shut off the microphone.

Like speakers, microphones are measured by their frequency ranges. This is not an important buying factor, however, because the human voice has a limited range. If you are recording only voices, consider an inexpensive microphone that covers a limited range of frequencies. An expensive microphone's recording capabilities extend to frequencies outside the voice's range. Why pay for something you won't be needing?

If you are recording music, invest in an expensive microphone, but be sure that your audio adapter can do justice to the signal produced by the microphone. A high-quality microphone can produce mediocre results when paired with a cheap 8-bit audio adapter.

Your biggest decision is to select a microphone that suits your recording style. If you work in a noisy office, you might want a unidirectional microphone that will prevent extraneous noises from being recorded. An omnidirectional microphone is best for recording a group conversation.

Some audio adapters include a microphone. This can be a small lapel microphone, a handheld microphone, or one with a desktop stand. If you want to keep your hands free, you might want to shun the traditional handheld microphone for a lapel or desktop model. If your audio adapter does not come with a microphone, see your local stereo or electronics parts store. Be sure that any microphone you purchase has the correct impedance to match the audio adapter's input.

If you're using software such as Dragon Naturally Speaking, IBM Via Voice, Philips FreeSpeech, or other voice-recognition software, use the microphone supplied with the software or choose from alternative models the software vendor recommends. Run the microphone setup program again if your software has trouble recognizing your voice. Some models feature a battery pack to boost sound quality; be sure to check the batteries and replace them to keep recognition quality high.

If you're talking but your voice-recognition or recording software isn't responding, check the following:

- *Incorrect jack.* It's easy to plug the microphone into the wrong jack. Try using a magic marker to color-code the microphone wire and jack to make matching up easier if your microphone or audio jack isn't color-coded or uses competing standards.
- *Check the recording volume in the mixer control.* This usually defaults to Mute to avoid spurious noise.
- *Make sure the microphone is turned on in the voice-recognition or recording software.* You must click the Record button in recording software, and many voice-recognition programs let you "pick up" the microphone for use or "put it down" when you need to answer the phone. Look for an onscreen microphone icon in the Windows System Tray for fast toggling between modes.

Chapter 15. I/O Interfaces from Serial and Parallel to IEEE 1394 and USB

[Introduction to Input/Output Ports](#)

[Universal Serial Bus](#)

[IEEE 1394](#)

[Standard Serial and Parallel Ports](#)

[Serial Ports](#)

[Parallel Ports](#)

Introduction to Input/Output Ports

This chapter covers the primary peripheral input/output ports on a modern PC system. This includes a discussion of both the so-called "legacy" serial and parallel ports that have been standard on PCs since the beginning, as well as a discussion of the more current Universal Serial Bus (USB), which is replacing both serial and parallel ports, and IEEE 1394 (i.LINK or FireWire) interfaces. (IEEE stands for the Institute of Electrical and Electronic Engineers.) Although SCSI and IDE are also I/O interfaces, they are mainly used as internal interfaces. IDE is covered in [Chapter 7](#), "The ATA/IDE Interface," even though desktop PCs today rarely implement SCSI. If you want to learn more about this architecture, please refer to my new book, *Upgrading and Repairing Servers*.

Currently, the two most popular high-speed serial-bus architecture families for desktop and portable PCs are Universal Serial Bus (USB) and IEEE 1394, which is also called i.LINK or FireWire. Each interface type is available in two versions: USB 1.1 and USB 2.0; IEEE 1394a and IEEE 1394b (also called FireWire 800). The USB and IEEE 1394 port families are high-speed communications ports that far outstrip the capabilities of older standard serial and parallel ports. They can also be used as an alternative to SCSI for high-speed external peripheral connections. In addition to performance, these newer ports offer I/O device consolidation, which means that all types of external peripherals can connect to these ports.

Why Serial?

As mentioned in the previous section, the technology behind both USB and IEEE 1394 is serial in nature. The current trend in high-performance peripheral bus design is to use a serial architecture, in which 1 bit at a time is sent down a wire. Because parallel architecture (used by SCSI, ATA, and LPT ports) uses 8, 16, or more wires to send bits simultaneously, the parallel bus is actually much faster at the same clock speed. However, increasing the clock speed of a serial connection is much easier than increasing that of a parallel connection.

Parallel connections in general suffer from several problems, the biggest being signal skew and jitter. Skew and jitter are the reasons high-speed parallel buses such as SCSI (small computer systems interface) are limited to short distances of 3 meters or less. The problem is that, although the 8 or 16 bits of data are fired from the transmitter at the same time, by the time they reach the receiver, propagation delays have conspired to allow some bits to arrive before the others. The longer the cable, the longer the time between the arrival of the first and last bits at the other end! This *signal skew*, as it is called, prevents you from running a high-speed transfer rate or a longer cable or both. *Jitter* is the tendency for the signal to reach its target voltage and float above and below for a short period of time.

With a serial bus, the data is sent 1 bit at a time. Because there is no worry about when each bit will arrive, the clocking rate can be increased dramatically. For example, the top transfer rate possible with EPP/ECP parallel ports is 2.77MBps, whereas IEEE 1394a ports (which use high-speed serial technology) support transfer rates as high as 400Mbps (about 50MBps) 25 times faster than parallel ports. USB 2.0 supports transfer rates of 480Mbps (about 60MBps), which is about 30 times faster than parallel ports, and the new IEEE 1394b (FireWire 800) ports reach transfer rates as high as 800Mbps (or about 100MBps), which is about 50 times faster than parallel ports!

At high clock rates, parallel signals tend to interfere with each other. Serial again has an advantage because, with only one or two signal wires, crosstalk and interference between the wires in the cable are

negligible.

In general, parallel cabling is more expensive than serial cabling. Besides the many additional wires needed to carry the multiple bits in parallel, the cable also must be specially constructed to prevent crosstalk and interference between adjacent data lines. This is one reason external SCSI cables are so expensive. Serial cabling, by comparison, is very inexpensive. For one thing, it has significantly fewer wires. Furthermore, the shielding requirements are far simpler, even at very high speeds. Because of this, transmitting serial data reliably over longer distances is also easier, which is why parallel interfaces have shorter recommended cable lengths than do serial interfaces.

For these reasons in addition to the need for Plug and Play external peripheral interfaces and the elimination of the physical port crowding on portable computers these high-performance serial buses were developed. USB is a standard feature on virtually all PCs today; is used for most general-purpose, high-speed external interfacing; and is the most compatible, widely available, and fastest general-purpose external interface. In addition, IEEE 1394 (more commonly known as FireWire), although mainly used in certain niche markets such as connecting DV (digital video) camcorders is also spreading into other high-bandwidth uses, such as high-resolution scanners, external hard drives, and networking.

Comparing IEEE 1394 and USB

Although both USB and IEEE 1394 are discussed in detail in the following sections, it's helpful to first compare them. Because of the similarity in both the form and function of USB and 1394 ports, there has been some confusion about the differences between them. [Table 15.1](#) summarizes the differences between these technologies.

Table 15.1. IEEE 1394 and USB Comparison

	IEEE 1394a (also called I.LINK or FireWire 400)	IEEE 1394b (also called FireWire 800)	USB 1.1	USB 2.0
PC-host required	No	No	Yes	Yes/No ^[1]
Maximum number of devices	63	63	127	127
Hot-swappable	Yes	Yes	Yes	Yes
Maximum cable length between devices	4.5 meters	4.5 meters (9-pin copper); 100 meters (glass optical fiber) ^[2]	5 meters	5 meters
Transfer rate	400Mbps (50MBps)	800Mbps (100MBps)	12Mbps (1.5MBps)	480Mbps (60MBps)

Proposed future transfer rates	None	1,600Mbps (400MBps); 3,200Mbps (800MBps)	None	None
Typical devices	DV camcorders; highres digital cameras; HDTV; set-top boxes; high-speed drives; high-res scanners; electronic musical instruments	All 1394a devices	Keyboards; mice; joysticks; low-res digital cameras; low-speed drives; modems; printers; low-res scanners	All USB 1.1 devices; DV camcorders; high-res digital cameras; HDTV; set-top boxes; high-speed drives; high-res scanners

[1] *No with USB On-The-Go.*

[2] *CAT-5 UTP supported for 100Mbps speeds (100 meters max.); step-index plastic optical fiber supported for 100Mbps and 200Mbps speeds (50 meters max.).*

Because the overall performance and physical specifications are similar, the main difference between USB and 1394 is popularity. The bottom line is that USB is by far the most popular external interface for PCs, eclipsing all others by comparison. This is primarily because Intel developed most of USB and has placed built-in USB support in all its motherboard chipsets and motherboards since 1996. Few motherboard chipsets integrate 1394a or 1394b; in most cases, it has to be added as an extra-cost chip to the motherboard. The cost of the additional 1394 circuitry (and a \$0.25 royalty paid to Apple Computer per system) and the fact that all motherboards already have USB, have limited the popularity of 1394 (FireWire) in the PC marketplace.

Even with the overwhelming popularity of USB, a market for 1394 still exists. Perhaps the main reason 1394 will survive in conjunction with the USB 2.0 interface is that USB began as a PC-centric technology, whereas 1394 is not. In other words, USB and Hi-Speed USB initially required a PC as the host, whereas 1394 can connect two devices directly without a PC between them. As such, 1394 could be used to directly connect a DV camcorder to a DV-VCR for dubbing tapes or editing.

Even this has changed, however, with the introduction of a supplement to the USB 2.0 specification called USB On-The-Go. USB On-The-Go, introduced in December 2001, enables the same device-to-device connections as was capable in 1394 (FireWire) and essentially nullifies the primary advantage 1394 had over USB. Because of the popularity and capabilities of USB, I recommend seeking out only USB peripherals over their 1394 (FireWire) counterparts where possible.

Because both USB 2.0 and 1394a (FireWire) offer relatively close to the same overall capabilities and performance, you should make your choice based on which devices you intend to connect. If the digital video camera you want to connect has only a 1394 (FireWire/i.LINK) connection, you will need to add a 1394 FireWire card to your system, if such a connection isn't already present on your motherboard. Most general-purpose PC storage, I/O peripherals, and other devices are USB, whereas only video and some storage devices usually have 1394 connections. However, many devices now offer both USB 2.0 and 1394 interfaces to enable use with the widest range of computers.

Universal Serial Bus

Universal Serial Bus (USB) is an external peripheral bus standard designed to bring Plug and Play capability for attaching peripherals externally to the PC. USB eliminates the need for special-purpose ports, reduces the need to use special-purpose I/O cards (thus reducing the need to reconfigure the system with each new device added), and saves important system resources such as interrupts (IRQs); regardless of the number of devices attached to a system's USB ports, only one IRQ is required. PCs equipped with USB enable peripherals to be automatically recognized and configured as soon as they are physically attached, without the need to reboot or run setup. USB allows up to 127 devices to run simultaneously on a single bus, with peripherals such as monitors and keyboards acting as additional plug-in sites, or hubs. USB cables, connectors, hubs, and peripherals can be identified by icons, as shown in [Figure 15.1](#). Note the "plus" symbol added to the upper icon, which indicates that port supports USB 2.0 (Hi-Speed USB) in addition to the standard 1.x support.

Figure 15.1. These icons identify USB cables, connectors, hubs, and peripherals.

Intel has been the primary proponent of USB, and all its PC chipsets starting with the PIIX3 South Bridge chipset component (introduced in February 1996) have included USB support as standard. Other chipset vendors have followed suit, making USB as standard a feature of today's desktop and notebook PCs as the serial and parallel ports once were.

Six other companies initially worked with Intel in codeveloping the USB, including Compaq, Digital, IBM, Microsoft, NEC, and Northern Telecom. Together, these companies have established the USB Implementers Forum (USB-IF) to develop, support, and promote USB architecture.

◀◀ See "[Chipsets](#)," p. [253](#).

The USB-IF formally released USB 1.0 in January 1996, USB 1.1 in September 1998, and USB 2.0 in April 2000. The 1.1 revision was mostly a clarification of some issues related to hubs and other areas of the specification. Most devices and hubs should be 1.1 compliant, even if they were manufactured before the release of the 1.1 specification. The biggest change was USB 2.0, which is 40 times faster than the original USB and yet fully backward compatible. USB ports can be retrofitted to older computers that lack built-in USB connectors through the use of either an add-on PCI card (for desktop computers) or a PC Card on Cardbus-compatible notebook computers. You can also use USB add-on cards to update an older system that has only USB 1.1 on the motherboard. As of mid-2002, virtually all motherboards include four or more USB 2.0 ports as standard. Notebook computers were slower to catch on; it wasn't until early 2003 that most notebook or laptop computers included USB 2.0 ports as standard.

USB Technical Details

USB 1.1 runs at 12Mbps (1.5MBps) over a simple four-wire connection. The bus supports up to 127 devices connected to a single root hub and uses a tiered-star topology, built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes.

Note that although the standard allows up to 127 devices to be attached, they all must share the 1.5MBps bandwidth, meaning that for every active device you add, the bus will slow down some. In practical reality, few people will have more than 8 devices attached at any one time.

For low-speed peripherals, such as pointing devices and keyboards, the USB also has a slower 1.5Mbps subchannel. The subchannel connection is used for slower interface devices, such as keyboards and mice.

USB employs what is called Non Return to Zero Invert (NRZI) data encoding. NRZI is a method of encoding serial data in which 1s and 0s are represented by opposite and alternating high and low voltages where there is no return to a zero (or reference) voltage between the encoded bits. In NRZI encoding, a 1 is represented by no change in signal level, and a 0 is represented by a change in level. A string of 0s causes the NRZI data to toggle each bit time; a string of 1s causes long periods with no transitions in the data. This is an efficient transfer encoding scheme because it eliminates the need for additional clock pulses that would otherwise waste time and bandwidth.

USB devices are considered either *hubs* or *functions*, or both. Functions are the individual devices that attach to the USB, such as a keyboard, mouse, camera, printer, telephone, and so on. Hubs provide additional attachment points to the USB, enabling the attachment of more hubs or functions. The initial ports in the PC system unit are called the *root hub*, and they are the starting point for the USB. Most motherboards have two, three, or four USB ports, any of which can be connected to functions or additional hubs. Some systems place one or two of the USB ports in the front of the computer, which is very convenient for devices you use only occasionally, such as digital cameras or flash memory card readers. External hubs (also called *generic hubs*) are essentially wiring concentrators, and through a star-type topology they allow the attachment of multiple devices. Each attachment point is referred to as a *port*. Most hubs have either four or eight ports, but more are possible. For more expandability, you can connect additional hubs to the ports on an existing hub. The hub controls both the connection and distribution of power to each of the connected functions. A typical hub is shown in [Figure 15.2](#).

Figure 15.2. A typical USB hub with four ports.

Besides providing additional sockets for connecting USB peripherals, a hub provides power to any attached peripherals. A hub recognizes the dynamic attachment of a peripheral and provides at least 0.5W of power per peripheral during initialization. Under control of the host PC driver software, the hub can provide more device power, up to a maximum of 2.5W, for peripheral operation.

Tip

For the most reliable operation, I recommend that you use self-powered hubs, which plug into an AC adapter. Bus-powered hubs pull power from the PC's USB root hub connector and aren't always capable of providing adequate power for high-power requirement devices, such as optical mice.

A newly attached hub is assigned a unique address, and hubs can be cascaded up to five levels deep (see [Figure 15.3](#)). A hub operates as a bidirectional repeater and repeats USB signals as required both upstream (toward the PC) and downstream (toward the device). A hub also monitors these signals and handles transactions addressed to itself. All other transactions are repeated to attached devices. A USB 1.1 hub supports both 12Mbps (full-speed) and 1.5Mbps (low-speed) peripherals.

Figure 15.3. A typical PC with USB devices can use multiple USB hubs to support a variety of peripherals, connected to whichever hub is most convenient.

Maximum cable length between two full-speed (12Mbps) devices or a device and a hub is 5 meters using twisted-pair shielded cable with 20-gauge wire. Maximum cable length for low-speed (1.5Mbps) devices using non-twisted-pair wire is 3 meters. These distance limits are shorter if smaller-gauge wire is used (see [Table 15.2](#)).

Table 15.2. Maximum Cable Lengths Versus Wire Gauge

Gauge Resistance (in Ohms/Meter Ω /m) Length (Max.)

28	0.232 Ω /m	0.81m
26	0.145 Ω /m	1.31m
24	0.091 Ω /m	2.08m
22	0.057 Ω /m	3.33m
20	0.036 Ω /m	5.00m

Although USB 1.1 is not as fast at data transfer as FireWire or SCSI, it is still more than adequate for the types of peripherals for which it is designed. USB 2.0 operates a surprising 40 times faster than USB 1.1 and allows transfer speeds of 480Mbps or 60MBps. Because it is fully backward-compatible and supports older 1.1 devices, I recommend purchasing only motherboards and add-in USB cards that conform to the faster USB 2.0 (Hi-Speed USB) standard. One of the additional benefits of USB 2.0 is the capability to handle concurrent transfers, which enables your USB 1.1 devices to transfer data at the same time without tying up the USB bus.

USB 2.0 drivers were not provided with the initial launch of Windows XP but are available through system update downloads or service packs. Use the Windows Update feature to connect to the Microsoft site and download any updates as necessary. Add-on USB 2.0 cards might include their own drivers, which should be installed.

Four main styles of connectors are specified for USB, called Series A, Series B, Mini-A, and Mini-B connectors. The A connectors are used for upstream connections between a device and the host or a hub. The USB ports on motherboards and hubs are usually Series A connectors. Series B connectors are designed for the downstream connection to a device that has detachable cables. In all cases, the mini connectors are simply smaller versions of the larger ones, in a physically smaller form factor for smaller devices.

The physical USB plugs are small (especially the mini plugs) and, unlike a typical serial or parallel cable, the plug is not attached by screws or thumbscrews. There are no pins to bend or break, making USB devices very user friendly to install and remove. The USB plug shown in [Figure 15.4](#) snaps into place on the USB connector.

Figure 15.4. USB Series A and Series B plugs and receptacles.

Note that a Mini-A/B socket is a dual-purpose socket that can accept either Mini-A or Mini-B plugs. The newer mini plugs and sockets have plastic portions inside the connectors that are required to be color-coded as shown in [Table 15.3](#).

Table 15.3. Color-Coding for USB Mini-Plugs and Sockets

Connector	Color
Mini-A socket	White
Mini-A plug	White
Mini-B socket	Black
Mini-B plug	Black
Mini-A/B socket	Gray

Tables 15.4 and 15.5 show the pinouts for the USB connectors and cables. Most systems with USB connectors feature one or two pairs of Series A plugs on the rear of the system. Some also feature one or two pairs on the front of the system for ease of use with items that are not permanently connected.

Table 15.4. USB Connector Pinouts for Series A/B Connectors

Pin	Signal Name	Wire Color	Comment
1	Vbus	Red	Bus power
2	- Data	White	Data transfer
3	+ Data	Green	Data transfer
4	Ground	Black	Cable ground
Shell	Shield		Drain wire

Table 15.5. USB Connector Pinouts for Mini-A/B Connectors

Pin	Signal Name	Wire Color	Comment
1	Vbus	Red	Bus power
2	- Data	White	Data transfer
3	+ Data	Green	Data transfer
4	ID		A/B identification ^[*]
4	Ground	Black	Cable ground
Shell	Shield		Drain wire

^[*] Used to identify a Mini-A from a Mini-B connector to the device. ID is connected to Ground in a Mini-A plug and not connected (open) in a Mini-B plug.

USB conforms to Intel's Plug and Play (PnP) specification, including hot plugging, which means that devices can be plugged in dynamically without powering down or rebooting the system. Simply plug in the device, and the USB controller in the PC detects the device and automatically determines and allocates the required resources and drivers. Microsoft has developed USB drivers and included them automatically in Windows 98 and later.

Windows 95B and 95C have very limited support for USB 1.1; the necessary drivers are not present in the original Windows 95 or 95A. With Windows 95B, the USB drivers are not automatically included; they are provided separately, although a late release of Windows 95 includes USB support. Many USB devices will not work with *any* Windows 95 release, including those that have the USB support files included.

Windows 98 and later have USB 1.1 support built in; however, additional drivers are required for USB 2.0 or later. In most cases, these drivers can be downloaded from Microsoft using the Windows Update feature.

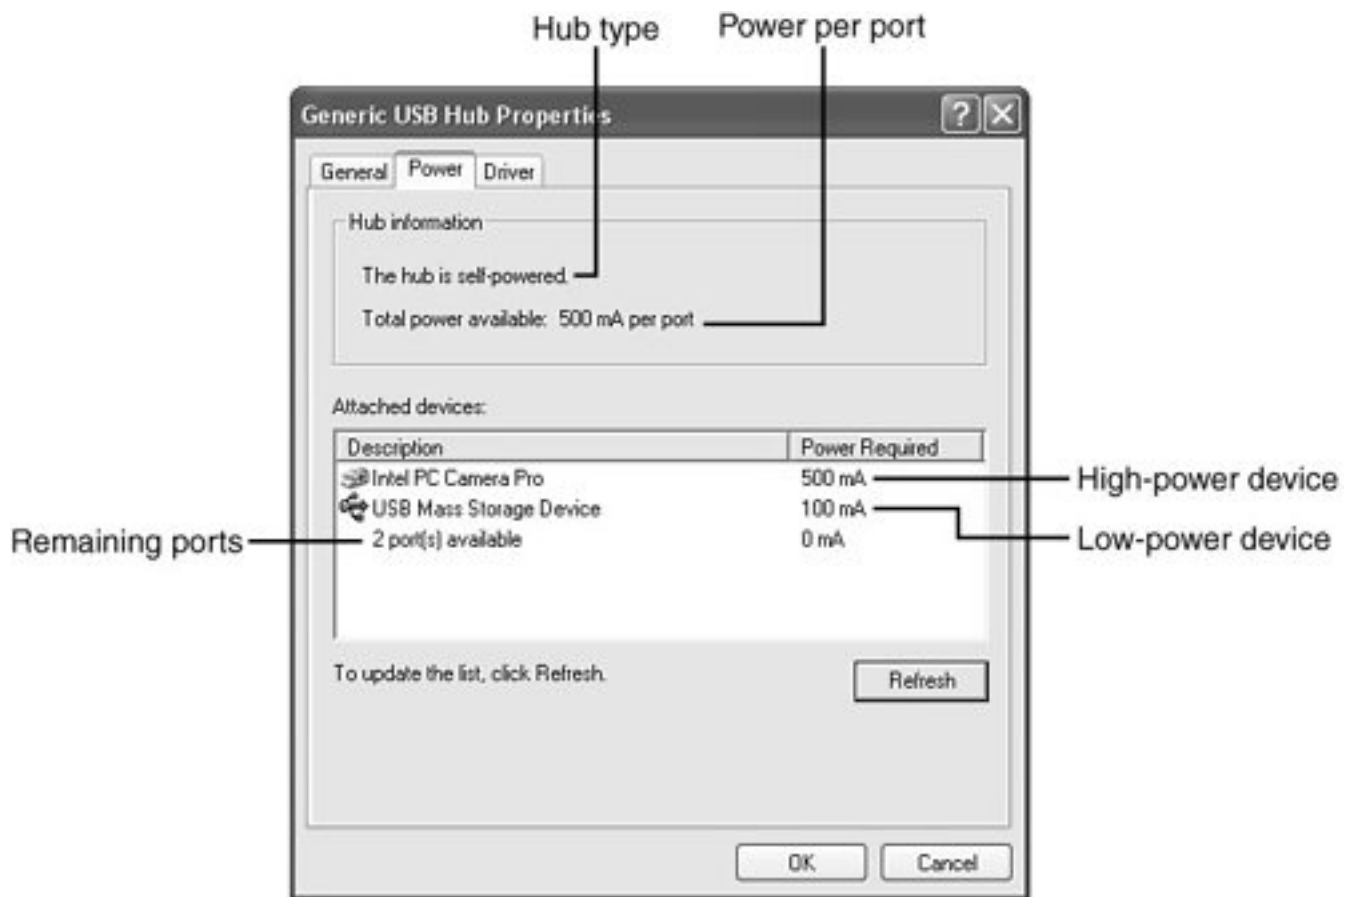

USB support is also required in the BIOS for devices such as keyboards and mice. This is included in all newer systems with USB ports built in. Aftermarket PCI and PC Card boards also are available for adding USB to systems that don't include it as standard on the motherboard. USB peripherals include printers, CD-ROMs, modems, scanners, telephones, joysticks, keyboards, and pointing devices such as mice and trackballs.

A free utility called USBReady is available from <http://www.usb.org>; it examines your PC's hardware and software and informs you of your PC's USB capabilities. Most PCs built in 1995 or earlier don't support USB. During 1996 most PC motherboards began supporting USB, and if your system dates from 1997 to 1998 or later, USB support is almost a certainty.

One interesting feature of USB is that, with certain limitations, attached devices can be powered by the USB bus. The PnP aspects of USB enable the system to query the attached peripherals as to their power requirements and issue a warning if available power levels are being exceeded. This is important for USB when it is used in portable systems because the battery power that is allocated to run the external peripherals might be limited. You can determine the amount of power available to each port in a USB root or generic hub and the amount of power required by a USB peripheral with the Windows Device Manager (see [Figure 15.5](#)).

Figure 15.5. The Power tab of the properties sheet for a USB generic hub lists available power and power usage by device.

[\[View full size image\]](#)

Devices that use more than 100mA, such as the webcam shown in [Figure 15.5](#), must be connected to a root hub or a self-powered generic hub. Devices that use 100mA or less can be connected to bus-powered hubs, such as those built in to some keyboards and monitors.

Tip

If a device plugged in to a self-powered hub stops working, check the power source for the self-powered hub; it might have failed or been disconnected. In such cases, a self-powered hub becomes a bus-powered hub, providing only 100mA per port instead of the 500mA per port available in self-powered mode.

To avoid running out of power when connecting USB devices, use a self-powered hub.

Another of the benefits of the USB specification is the self-identifying peripheral, a feature that greatly eases installation because you don't have to set unique IDs or identifiers for each peripheral; the USB handles that automatically. Also, USB devices can be "hot" plugged or unplugged, meaning that you do not have to turn off your computer or reboot every time you want to connect or disconnect a peripheral. However, to prevent data loss with USB drives and storage devices, you need to use the Eject Hardware or Safely Remove Hardware feature in the Windows system tray. Click the device, select Stop, click OK, and wait for the system to indicate that the device has been stopped before you remove it.

Enabling USB Support

Many systems shipped before Windows 98 was introduced in mid-1998 have onboard USB ports that were disabled at the factory. In some cases, especially with Baby-AT motherboards, there is no way to tell from the outside which systems have USB support built in. This is because many of these same systems were not shipped with the USB header cables necessary to bring the USB root hub connectors from the motherboard to the rear of the system.

If USB support is disabled in the system BIOS, restart your system and locate the BIOS setup screen that refers to the USB ports. Enable the USB feature. If you see a separate entry for USB IRQ, enable this as well. After you restart the computer with a USB-aware operating system, your "new" USB root hub will be detected and the drivers will be installed if you are using Windows 98 or newer; you might need to manually install drivers with late releases of Windows 95.

If your system has USB connectors present, you also will be able to use the "new" USB ports as soon as the system is rebooted after the USB drivers are installed. However, if your motherboard vendor didn't provide USB connectors, you must buy USB header cables. Before you order them, check the configuration of your motherboard's USB header pins. The standard is two rows of five pins each. Companies such as Belkin, CyberGuys, and Cables To Go sell header cables that are compatible with standard USB header pins if your motherboard supplier doesn't have the header cable in stock. [Figure 15.6](#) shows a typical USB header cable set.

Figure 15.6. A typical USB header cable set; plug it into your motherboard to connect devices to the additional onboard USB ports (if present).

One of the biggest advantages of an interface such as USB is that it requires only a single interrupt (IRQ) from the PC. Therefore, you can connect up to 127 devices and they will not use separate interrupts, as they might if each were connected over a separate interface. This is a major benefit of the USB interface.

The USB interface can also be adapted to older peripherals. See the section "[USB Adapters](#)," later in this chapter, for details.

USB 2.0/Hi-Speed USB

USB 2.0 (also called Hi-Speed USB) is a backward-compatible extension of the USB 1.1 specification that uses the same cables, connectors, and software interfaces, but it runs 40 times faster than the original 1.0 and 1.1 versions. The higher speed enables higher-performance peripherals, such as higher-resolution web/videoconferencing cameras, scanners, and faster printers, to be connected externally with the same easy plug-and-play installation of current USB peripherals. From the end user's point of view, USB 2.0 works exactly the same as 1.1 only faster and with more interesting, higher-performance devices available. All existing USB 1.1 devices work in a USB 2.0 bus because USB 2.0 supports all the slower-speed connections. USB data rates are shown in [Table 15.6](#).

Table 15.6. USB Data Rates

Interface	Megabits per Second	Megabytes per Second
USB 1.1 low speed	1.5Mbps	0.1875MBps
USB 1.1 full speed	12Mbps	1.5MBps
USB 2.0 high speed	480Mbps	60MBps

If your motherboard or system features USB 2.0-compatible (Hi-Speed USB) ports, you might need to enable USB 2.0/Hi-Speed USB support in the system BIOS and install an appropriate driver. Otherwise, USB 2.0/Hi-Speed USB ports will be used as USB 1.1 ports.

◀◀ See "[USB Configuration Submenu](#)," p. [456](#), for details.

The support of higher-speed USB 2.0 peripherals requires using a USB 2.0 hub. You can still use older USB 1.1 hubs on a 2.0 bus, but any peripherals or additional hubs connected downstream from a 1.1 hub will operate at the slower 1.5MBps USB 1.1 maximum speed. Devices connected to USB 2.0 hubs will operate at the maximum speed of the device, up to the full USB 2.0 speed of 60MBps. The higher transmission speeds through a 2.0 hub are negotiated on a device-by-device basis, and if the higher speed is not supported by a peripheral, the link operates at a lower USB 1.1 speed.

As such, a USB 2.0 hub accepts high-speed transactions at the faster USB 2.0 frame rate and must deliver them to high-speed USB 2.0 peripherals as well as USB 1.1 peripherals. This data rate matching responsibility requires increased complexity and buffering of the incoming high-speed data. When communicating with an attached USB 2.0 peripheral, the 2.0 hub simply repeats the high-speed signals; however, when communicating with USB 1.1 peripherals, a USB 2.0 hub buffers and manages the transition from the high speed of the USB 2.0 host controller (in the PC) to the lower speed of a USB 1.1 device. This feature of USB 2.0 hubs means that USB 1.1 devices can operate along with USB 2.0 devices and not consume any additional bandwidth. Some manufacturers of add-on USB 2.0 cards are equipping the cards with both external and internal USB 2.0 ports.

How can you tell which devices are designed to support USB 1.1 and which support the emerging USB 2.0

standard? The USB Implementer's Forum (USB-IF), which owns and controls the USB standard, introduced new logos in late 2000 for products that have passed its certification tests. The logos are shown in [Figure 15.7](#).

Figure 15.7. The USB-IF USB 1.1compliant logo (left) compared to the USB-IF USB 2.0compliant logo (right).

As you can see from [Figure 15.7](#), USB 1.1 is also known simply as USB, and USB 2.0 is also known as Hi-Speed USB. Also note the icons shown earlier, where the addition of the plus symbol to the standard USB trident is used to identify ports that support USB 2.0.

USB On-The-Go

In December 2001, the USB-IF released a supplement to the USB 2.0 standard called USB On-The-Go. It was designed to address the one major shortcoming of USB: the fact that a PC was required to transfer data between two devices. In other words, you couldn't connect two cameras together and transfer pictures between them without a PC orchestrating the transfer. With USB On-The-Go, however, devices that conform to the specification still work normally when they are connected to a PC, but they also have additional capabilities when connected to other devices supporting the standard.

Although this capability can also work with PC peripherals, it was mainly added to address issues using USB devices in the consumer electronics area, where a PC might not be available. Using this standard, devices such as digital video recorders can connect to other recorders to transfer recorded movies or shows, items such as personal organizers can transfer data to other organizers, and so on. The addition of the On-The-Go supplement to USB 2.0 greatly enhances the use and capabilities of USB both in the PC and consumer electronics markets.

USB Adapters

If you still have a variety of older peripherals and yet you want to take advantage of the USB connector on your motherboard, several signal converters or adapters are available. Companies such as Belkin and others currently have adapters in the following types:

- USB-to-parallel (printer)
- USB-to-serial
- USB-to-SCSI
- USB-to-Ethernet
- USB-to-keyboard/mouse
- USB-to-TV/video

These adapters usually look just like a cable, with a USB connector at one end (which you plug into your USB port) and various other interface connectors at the other end. In some cases, you attach standard USB and device cables to a standalone adapter, such as with the USB-to-Ethernet adapter shown in [Figure 15.8](#).

Figure 15.8. A typical USB-to-Ethernet adapter from D-Link.

There is more to these devices than just a cable: If the unit is a one-piece device, active electronics are hidden in a module along the cable or are sometimes packed into one of the cable ends. The electronics are powered by the USB bus and convert the signals to the appropriate other interface. If you cannot install a native adapter card for your device, converting it to use the USB port through an adapter is much better than not using the device at all. For example, a USB-to-Ethernet adapter such as the one shown in [Figure 15.8](#) can enable a computer without expansion slots to connect to a broadband Internet device such as a cable or DSL modem.

However, some drawbacks do exist to these adapters. For example, USB-to-parallel converters work only with printers and not other parallel-connected devices, such as scanners, cameras, external drives, and so on. Before purchasing one of these adapters, ensure that it will work with the device or devices you have in mind. If you need to use more than one non-USB device with your system, consider special USB hubs that also contain various combinations of other port types; these are sometimes referred to as *multifunction USB hubs*, *USB port replicators*, or *USB docking stations*. These special hubs are more expensive than USB-only hubs but are less expensive than the combined cost of a comparable USB hub and two or more USB adapters.

Another type of adapter available is a direct-connect cable, which enables you to connect two USB-equipped PCs directly together using USB as a network. These are popular for people playing two-player games, with each player on his own system. Another use is for transferring files because this connection

usually works as well or better than the direct parallel connection that otherwise might be used. Also available are USB switchboxes that enable one peripheral to be shared among two or more USB buses. Note that both the direct connect cables and USB switchboxes are technically not allowed as a part of the USB specification, although they do exist.

Legacy-Free PCs

USB adapters might find more use in the future as more and more legacy-free PCs are shipped. A *legacy-free PC* is one that lacks any components that were connected to or a part of the traditional ISA bus. This especially includes the otherwise standard Super I/O chip, which integrated serial, parallel, keyboard, mouse, floppy, and other connections. A legacy-free motherboard therefore does not have the standard serial, parallel, and keyboard/mouse connectors on the back and lacks an integrated floppy controller. The devices previously connected to those ports must instead be connected via USB, ATA/IDE, PCI, and other interfaces.

Legacy-free systems are primarily found on the low-end, consumer-oriented systems. For those systems, USB will likely be one of the only external connections provided. To compensate for the loss of the other external interfaces, most legacy-free motherboards feature four or more integrated USB connectors on one or two buses.

IEEE 1394

The *Institute of Electrical and Electronic Engineers* Standards Board introduced IEEE 1394 (or just 1394 for short) in late 1995. The number comes from the fact that this happened to be the 1,394th standard they published. It is the result of the large data-moving demands of today's audio and video multimedia devices. The key advantage of 1394 is that it's extremely fast; the popular 1394a standard supports data transfer rates up to an incredible 400Mbps.

1394 Standards

The most common version of the 1394 standard is actually referred to as 1394a, or sometimes as 1394a-2000 for the year it was adopted. The 1394a standard was introduced to solve interoperability and compatibility issues in the original 1394 standard; it uses the same connectors and supports the same speeds as the original 1394 standard.

The first products to use the 1394b standard were introduced in early 2003. Initially, 1394b supports 800Mbps transfer rates, but future versions of the standard might reach speeds of up to 3,200Mbps. 1394b will be capable of reaching much higher speeds than the current 1394/1394a standard because it will also support network technologies such as glass and plastic fiber-optic cable and Category 5 UTP cable, increased distances when Category 5 cabling is used between devices, and improvements in signaling. 1394b will also be fully backward-compatible with 1394a devices. 1394 is also known by two other common names: i.LINK and FireWire. *i.LINK* is an IEEE 1394 designation initiated by Sony in an effort to put a more user-friendly name on IEEE 1394 technology. Most companies that produce 1394 products for PCs have endorsed this new name initiative. Originally, the term *FireWire* was an Apple-specific trademark that Apple licensed to vendors on a fee basis. However, in May 2002, Apple and the 1394 Trade Association announced an agreement to allow the trade association to provide no-fee licenses for the FireWire trademark on 1394-compliant products that pass the trade association's tests. Apple continues to use *FireWire* as its marketing term for IEEE 1394 devices. FireWire 400 refers to Apple's IEEE 1394a-compliant products, whereas FireWire 800 refers to Apple's IEEE 1394b-compliant products.

1394a Technical Details

The IEEE 1394a standard currently exists with three signaling rates: 100Mbps, 200Mbps, and 400Mbps (12.5MBps, 25MBps, and 50MBps). Most PC adapter cards support the 400Mbps (50MBps) rate, although device speeds can vary. A maximum of 63 devices can be connected to a single IEEE 1394 adapter card by way of daisy-chaining or branching. 1394 devices, unlike USB devices, can be used in a daisy-chain without using a hub, although hubs are recommended for devices that will be hot-swapped. Cables for IEEE 1394/1394a devices use Nintendo GameBoy-derived connectors and consist of six conductors: Four wires transmit data, and two wires conduct power. Connection with the motherboard is made either by a dedicated IEEE 1394 interface or by a PCI adapter card. [Figure 15.9](#) shows the 1394/1394a cable, socket, and connector.

Figure 15.9. IEEE 1394 port, 6-pin cable, and 4-pin cable.

The 1394 bus was derived from the FireWire bus originally developed by Apple and Texas Instruments, and it is also a part of a new Serial SCSI standard.

1394a uses a simple six-wire cable with two differential pairs of clock and data lines, plus two power lines; the four-wire cable end shown in [Figure 15.9](#) is used with self-powered devices, such as DV camcorders. Just as with USB, 1394 is fully PnP, including the capability for hot-plugging (insertion and removal of components without powering down). Unlike the much more complicated parallel SCSI bus, 1394 does not require complicated termination, and devices connected to the bus can draw up to 1.5 amps of electrical power. 1394 offers equal or greater performance compared to ultra-wide SCSI, with a much less expensive and less complicated connection.

1394 is built on a daisy-chained and branched topology, and it allows up to 63 nodes, with a chain of up to 16 devices on each node. If this is not enough, the standard also calls for up to 1,023 bridged buses, which can interconnect more than 64,000 nodes! Additionally, as with SCSI, 1394 can support devices with various data rates on the same bus. Most 1394 adapters have three nodes, each of which can support 16 devices in a daisy-chain arrangement. Some 1394 adapters also support internal 1394 devices.

The types of devices that can be connected to the PC via 1394 mainly include video cameras; editing equipment; and all forms of disk drives, including hard disk, optical, floppy, CD-ROM, and DVD-ROM drives. Also, digital cameras, tape drives, high-resolution scanners, and many other high-speed peripherals that feature 1394 have interfaces built in. The 1394 bus appears in some desktop and portable computers as a replacement or supplement for other external high-speed buses, such as USB or SCSI.

Chipsets and PCI adapters for the 1394 bus are available from a number of manufacturers, including some models that support both 1394 and other port types in a single slot. Microsoft has developed drivers to support 1394 in Windows 9x and later, including Windows XP. The most popular devices that conform to the IEEE 1394 standard are camcorders and VCRs with digital video capability. Sony was among the first to release such devices (under the i.LINK name). In typical Sony fashion, however, its products have a unique four-wire connector that requires an adapter cord to be used with IEEE 1394 PC Cards, and Sony doesn't even call it IEEE 1394 or FireWire; it created its own designation (i.LINK) instead. DV products using 1394 also are available from Panasonic, Sharp, JVC, and others. Noncomputer IEEE 1394 applications include DV conferencing devices, satellite audio and video data streams, audio synthesizers, DVD, and other high-

speed disc drives.

Because of the current DV emphasis for IEEE 1394 peripherals, many FireWire cards currently offered are bundled with DV capturing and editing software. With a DV camera or recording equipment, these items provide substantial video editing and dubbing capabilities on your PC. Of course, you need IEEE 1394 I/O connectivity, which is a growing, but still somewhat rare, feature on current motherboards.

IEEE 1394b Technical Details

IEEE 1394b is the second generation of the 1394 standard, with the first products (high-performance external hard drives) introduced in January 2003. IEEE 1394b uses one of two nine-pin cables and connectors to support speeds of 800Mbps/3200Mbps with copper or fiber-optic cabling. In addition to supporting faster transfer rates, 1394b has other features, including

- *Self-healing loops.* If you improperly connect 1394b devices together to create a logical loop, the interface corrects the problem instead of failing as with 1394a.
- *Continuous dual simplex.* Of the two wire pairs used, each pair transmits data to the other device, so that speed remains constant.
- *Support for fiber-optic and CAT5 network cable as well as standard 1394a and 1394b copper cable.*
- *Improved arbitration of signals to support faster performance and longer cable distances.*
- *Support for CAT5 cable, even though it uses pairs on pins 1 and 2 and 7 and 8 only for greater reliability.* It also doesn't require crossover cables.

The initial implementations of IEEE 1394b use a nine-wire interface with two pairs of signaling wires. However, to enable a 1394b port to connect to 1394a-compatible devices, there are two different versions of the 1394b port:

- Beta
- Bilingual

Beta connectors support only 1394b devices, whereas bilingual connectors can support both 1394b and 1394a devices. As [Figure 15.10](#) shows, the connectors and cables have the same pinout but are keyed differently.

Figure 15.10. Bilingual and beta 1394b connectors and cables. Many 1394b implementations use both types of connectors.

Note that bilingual sockets and cables have a narrower notch than beta sockets and cables. This prevents cables designed for 1394a devices from being connected to the beta socket. [Figure 15.11](#) compares a beta-to-beta 1394b cable to bilingual-to-1394a cables.

Figure 15.11. A beta-to-beta cable (top) compared to bilingualto4-pin (middle) and bilingualto6-pin 1394a devices (bottom).

Standard Serial and Parallel Ports

Traditionally, the most basic communications ports in any PC system have been the serial and parallel ports, and these ports continue to be important.

Serial ports (also known as *communication* or *COM* ports) originally were used for devices that had to communicate bidirectionally with the system. Such devices include modems, mice, scanners, digitizers, and any other devices that "talk to" and receive information from the PC. Newer parallel port standards now allow the parallel port to perform high-speed bidirectional communications.

Several companies manufacture communications programs that perform high-speed transfers between PC systems using serial or parallel ports. Versions of these file transfer programs have been included with DOS 6.0 and higher (Interlink) and with Windows 95 and newer versions (Direct Cable Connection [DCC]). Although USB continues to replace the parallel port in new computers, you can still purchase products that make nontraditional use of the parallel port. For example, external drive vendors continue to make CD-ROM, CD-RW, and DVD drives; floppy drives; print servers; and tape backups that connect to the parallel port, although many of these devices also include USB connections as well.

Serial Ports

The asynchronous serial interface was designed as a system-to-system communications port. *Asynchronous* means that no synchronization or clocking signal is present, so characters can be sent with any arbitrary time spacing.

Each character that is sent over a serial connection is framed by a standard start-and-stop signal. A single 0 bit, called the *start bit*, precedes each character to tell the receiving system that the next eight bits constitute a byte of data. One or two stop bits follow the character to signal that the character has been sent. At the receiving end of the communication, characters are recognized by the start-and-stop signals instead of by the timing of their arrival. The asynchronous interface is character oriented and has an approximate 20% overhead for the extra information that is needed to identify each character.

Serial refers to data that is sent over a single wire, with each bit lining up in a series as the bits are sent. This type of communication is used over the phone system because it provides one wire for data in each direction.

Typical Locations for Serial Ports

Typical systems include one or two serial ports, with connectors typically located at the rear of the system. Some recent consumer-oriented computers label a front-mounted serial port the "digital camera port." This name comes from the use of serial ports for data transfer from low-end digital cameras. On recent systems, these built-in serial ports are controlled by a highly integrated South Bridge chip in the latest motherboard designs.

If you need more serial ports than your system has as standard, you can purchase single- or multiport serial port cards or so-called *multi-I/O* cards that feature one or two serial ports and one or two parallel ports. Older systems based on the ISA or VL-Bus standard often have the serial ports attached to a multifunction card that also has IDE hard disk and floppy disk interfaces.

Note that card-based modems also incorporate a built-in serial port on the card as part of the modem circuitry. [Figure 15.12](#) shows the standard 9-pin connector used with most modern external serial ports. [Figure 15.13](#) shows the original standard 25-pin version.

Figure 15.12. AT-style 9-pin serial-port connector specifications.

External Device

Asynchronous Communications Adapter (RS-232C)

Serial ports can connect to a variety of devices, such as modems, plotters, printers, PDA docking devices, other computers, bar code readers, scales, and device control circuits.

The official specification recommends a maximum cable length of 50 feet. The limiting factor is the total load capacitance of cable and input circuits of the interface. The maximum capacitance is specified as 2500pF (picofarads). Special low-capacitance cables can effectively increase the maximum cable length greatly, to as much as 500 feet or more. Also available are line drivers (amplifier/repeaters) that can extend cable length even further. [Tables 15.7](#), [15.8](#), and [15.9](#) show the pinouts of the 9-pin (AT-style), 25-pin, and 9-pin-to-25-pin serial connectors, respectively.

Table 15.7. 9-Pin (AT) Serial Port Connector

Pin	Signal	Description	I/O
1	CD	Carrier detect	In
2	RD	Receive data	In
3	TD	Transmit data	Out
4	DTR	Data terminal ready	Out
5	SG	Signal ground	
6	DSR	Data set ready	In
7	RTS	Request to send	Out
8	CTS	Clear to send	In
9	RI	Ring indicator	In

5	7	SG	Signal ground
6	6	DSR	Data set ready
7	4	RTS	Request to send
8	5	CTS	Clear to send
9	22	RI	Ring indicator

Note

Macintosh systems use a similar serial interface, defined as RS-422. Most external modems can interface with RS-232 or RS-422, but it is safest to make sure that the external modem you get for your PC is designed for a PC, not a Macintosh.

UARTs

The heart of any serial port is the Universal Asynchronous Receiver/Transmitter (UART) chip. This chip completely controls the process of breaking the native parallel data within the PC into serial format and later converting serial data back into the parallel format.

Several types of UART chips have been available on the market. The original PC and XT used the 8250 UART, which was used for many years in low-priced serial cards. Starting with the first 16-bit systems, the 16450 UART typically was used. The only difference between these chips is their suitability for high-speed communications. The 16450 is better suited for high-speed communications than is the 8250; otherwise, both chips appear identical to most software. The 16550 UART was the first serial chip used in the IBM PS/2 line. Other 386 and higher systems rapidly adopted it. The 16550 functioned as the earlier 16450 and 8250 chips, but it also included a 16-byte buffer that aided in faster communications. This is sometimes referred to as a *FIFO (first in first out)* buffer. Unfortunately, the early 16550 chips had a few bugs, particularly in the buffer area. These bugs were corrected with the release of the 16550A. The most current version of the chip is the 16550D, which was released in 1995 and is produced by National Semiconductor.

Tip

The high-speed buffered 16550A (or newer) UART chip is pin for pin compatible with the 16450 UART. If your 16450 UART is socketed, a cheap and easy way to improve serial performance is to install a 16550 UART chip in the socket.

Because the 16550 is a faster, more reliable chip than its predecessors, it is best to ensure that your serial ports have that chip or an equivalent. If you are in doubt about which type of UART you have, use the Microsoft MSD program (provided with MS-DOS 6.x and Windows 9x/Me/2000) to determine the type of UART you have. Note that MSD often reports a 16450 UART as an 8250.

Note

Another way to tell whether you have a 16550 UART in Windows is to click the Start menu and then select Settings, Control Panel. In Windows 9x/Me, double-click Modems and then click the Diagnostics tab. Select the port you want to check in the list and click More Info. Windows communicates with the port to determine the UART type, and that information is listed in the Port Information portion of the More Info box.

In Windows 2000/XP or later, click Phone and Modem Options and then select Modems, Properties, Advanced, Advanced Port Settings. If the option labeled Use FIFO Buffers (Requires 16550 Compatible UART) is not grayed out, you have a 16550-compatible port.

The original designer of these UARTs is National Semiconductor (NS). So many other manufacturers are producing clones of these UARTs that you probably don't have an actual NS brand part in your system. Even so, the part you have is compatible with one of the NS parts, hopefully the 16550. In other words, check to see that whatever UART chip you have does indeed feature the 16-byte FIFO buffer, as found in the NS 16550 part.

See "[Super I/O Chips](#)," p. [342](#).

8250

IBM used this original chip in the PC serial port card. This chip had no transmit/receive buffer, so it was very slow. The chip also had several bugs, none of which were serious. The PC and XT ROM BIOSs were written to anticipate at least one of the bugs. The 8250B replaced this chip.

8250A

Do not use the second version of the 8250 in any system. This upgraded chip fixes several bugs in the 8250, including one in the interrupt enable register, but because the PC and XT ROM BIOSs expect the bug, this chip does not work properly with those systems. The 8250A works in an AT system that does not expect the bug, but it does not work adequately at 9600bps.

8250B

The last version of the 8250 fixes bugs from the previous two versions. The interrupt enable bug in the original 8250, which is expected by the PC and XT ROM BIOS software, has been put back into this chip, making the 8250B the most desirable chip for any non-AT serial port application. The 8250B chip might work in an AT under DOS, but it does not run properly at 9600bps because, like all 8250s, it has no transmit/receive buffer.

16450

IBM selected the higher-speed version of the 8250 for the AT. The higher performance comes mainly from a 1-byte transmit/receive buffer contained within the chip. Because this chip has fixed the aforementioned interrupt enable bug, the 16450 does not operate properly in many PC or XT systems because they expect this bug to be present. OS/2 requires this chip as a minimum; otherwise, the serial ports do not function properly. It also adds a scratch-pad register as the highest register. The 16450 is used primarily in AT systems because of its increase in throughput over the 8250B.

16550 Series

This chip is pin compatible with the 16450 but is much faster due to a built-in 16-character transmit/receive FIFO buffer. It also allows multiple DMA channel access. The original version of this chip did not allow the buffer to work, but all 16550A or later revisions have the bug fixed. The last version produced by National Semiconductor was called the 16550D. Use a version of this UART in your serial port if you do any communications at 9600bps or higher. If your communications program uses the FIFO and all of them do today it can greatly increase communications speed and eliminate lost characters and data at the higher speeds. Virtually all Super I/O chips contain the equivalent of dual 16550A or later chips. Most 16550 UARTs have a maximum communications speed of 115Kbps.

16650, 16750, and 16850

Several companies have produced versions of the 16550 with larger buffers:

- The 16550 has a 32-byte buffer.
- The 16750 has a 64-byte buffer.
- The 16850 has a 128-byte buffer.
- The 16950 has a 128-byte buffer and the option to run at normal or 4x normal baud rates.

These chips are not from National Semiconductor, and the designations only imply that they are compatible with the 16550 but have a larger buffer. These larger-buffered versions allow speeds of 230Kbps (16650), 460Kbps (16750), and 920Kbps (16850 and 16950) and are recommended when running a high-speed external communications link, such as an ISDN terminal adapter or external 56Kbps modem. These are discussed more in the following section.

High-Speed Serial Port Cards

If you are using external RS-232 devices designed to run at speeds higher than 115Kbps (the maximum speed of the 16550 series UARTs and equivalents), you can't achieve maximum performance unless you replace your existing serial ports with add-on cards using one of the 16650, 16750, 16850, or 16950 UARTs discussed earlier. Most cards allow raw port speed settings of 230Kbps, 460Kbps, or even higher, which is valuable when connecting a PC to a high-speed external component that is connected to a serial port, such as an ISDN terminal adapter. You can't really get the full-speed benefit of an external ISDN modem (terminal adapter) unless your serial port can go at least 230Kbps. Lava Computer Mfg. and SIIG are two of the companies that offer a complete line of high-speed serial and parallel port cards (see the Vendor List on the accompanying disc).

Onboard Serial Ports

Starting with late-model 486-based systems in the mid-1990s, a component on the motherboard called a *Super I/O* chip began to replace separate UART chips. This usually has two serial port UARTs as well as a multimode parallel port, floppy controller, keyboard controller, and sometimes the CMOS memory all built into a single tiny chip. Still, this chip acts as if all these separate devices were installed: That is, from a software point of view, both the operating system and applications still act as if separate UART chips were installed on serial port adapter cards. The most recent systems integrate the functions of a Super I/O chip into the South Bridge chip. As with the Super I/O chip, South Bridge chips with integrated I/O are transparent to software. Super I/O and South Bridge chips are discussed throughout this chapter and in [Chapter 4](#), "Motherboards and Buses."

Serial Port Configuration

Each time a character is received by a serial port, it has to get the attention of the computer by raising an interrupt request line (IRQ). Eight-bit ISA bus systems have eight of these lines, and systems with a 16-bit ISA bus have 16 lines. The 8259 interrupt controller chip or equivalent typically handles these requests for attention. In a standard configuration, COM1 uses IRQ4, and COM2 uses IRQ3. Even on the latest systems, the default COM port assignments remain the same for compatibility with older software and hardware.

When a serial port is installed in a system, it must be configured to use specific I/O addresses (called ports) and interrupts (called IRQs). The best plan is to follow the existing standards for how these devices are to be set up. For configuring serial ports, use the addresses and interrupts indicated in [Table 15.10](#).

Table 15.10. Standard

Serial I/O Port Addresses and Interrupts

COMx	I/O Ports	IRQ
COM1	3F83FFh	IRQ4
COM2	2F82FFh	IRQ3
COM3	3E83EFh	IRQ4 ^[1]
COM4	2E82EFh ^[2]	IRQ3 ^[1]

^[1] Note that although many serial ports can be set up to share IRQ3 and IRQ4 with COM1 and COM2, it is not recommended. The best recommendation is setting COM3 to IRQ10 and COM4 to IRQ11 (if available). If ports above COM3 are required, it is recommended that you purchase a special multiport serial board, preferably a PCI-based board that supports IRQ sharing without conflicts.

^[2] This I/O address can conflict with registers in some video cards. In such cases, you cannot use COM4 unless COM4 or the video card can be configured to use a different I/O port address range.

Be sure that, if you are adding more than the standard COM1 and COM2 serial ports, they use unique and nonconflicting interrupts. If you purchase a serial port adapter card and intend to use it to supply ports beyond the standard COM1 and COM2, be sure it can use interrupts other than IRQ3 and IRQ4; PCI-based serial port boards take advantage of IRQ sharing features to allow COM3 and above to use a single IRQ without conflicts.

Note that BIOS manufacturers never built support for COM3 and COM4 into the BIOS. Therefore, DOS can't work with serial ports above COM2 because DOS gets its I/O information from the BIOS. The BIOS finds out what is installed in your system, and where it is installed, during the power-on self test (POST). The POST checks only for the first two installed ports. This is not a problem under Windows because Windows 95 and later have built-in support for up to 128 ports.

With support for up to 128 serial ports in Windows, using multiport boards in the system is much easier. Multiport boards give your system the capability to collect or share data with multiple devices while using only one slot and one interrupt.

Caution

Sharing interrupts between COM ports or any devices can function properly sometimes and not others. It is recommended that you never share interrupts between multiple ISA-based serial ports, such as the COM ports built into your motherboard or found on an ISA modem. Trying to track down drivers, patches, and updates to allow this to work successfully if it's even possible in your system can cause you hours of frustration.

◀◀ See "[Resolving Resource Conflicts](#)," p. [393](#).

Testing Serial Ports

You can perform several tests on serial and parallel ports. The two most common types of tests are those that involve software only and those that involve both hardware and software. The software-only tests are done with diagnostic programs, such as Microsoft's MSD or the Modem diagnostics built into Windows, whereas the hardware and software tests involve using a wrap plug to perform loopback testing.

▶▶ See "[Advanced Diagnostics Using Loopback Testing](#)," p. [1001](#).

▶▶ See "[Testing Parallel Ports](#)," p. [1010](#).

Microsoft Diagnostics

Microsoft Diagnostics (MSD) is a diagnostic program supplied with MS-DOS 6.x, Windows 3.x, and Windows 9x/Me/2000. In Windows 95 this program can be found on the CD-ROM in the `\other\msd` directory, and in Windows 98/Me/2000, you can find it on the CD-ROM in the `\tools\oldmsdos` directory. MSD is not automatically installed when you install the operating system. To use it, you must run it from the CD-ROM directly or copy the program from the CD-ROM to your hard disk.

For the most accurate results, many diagnostics programs, such as MSD, are best run in a DOS-only environment. Because of this, you need to restart the machine in DOS mode before using them. If you use Windows 2000 or XP, you can format a floppy disk with MS-DOS startup files and use it to start your computer. Then, to use MSD, switch to the directory in which it is located. This is not necessary, of course, if the directory that contains the program is in your search path, which is often the case with the DOS 6.x or Windows-provided versions of MSD. Then, simply type **MSD** at the DOS prompt and press Enter. Soon you see the MSD screen.

Select the Serial Ports option. Notice that you are given information about which type of serial chip you have in your system, as well as information about which ports are available. If any of the ports are in use (with a mouse, for example), that information is provided as well.

MSD is helpful in at least determining whether your serial ports are responding. If MSD can't determine the existence of a port, it does not provide the report that indicates that the port exists. This sort of "look-and-see" test is the first action I usually take to determine why a port is not responding.

Troubleshooting Ports in Windows

Windows 9x/Me can tell you whether your ports are functioning. First, you must verify that the required communications files are present to support the serial ports in your system:

1.

Verify the file sizes and dates of both **COMM.DRV** (16-bit serial driver) and **SERIAL.VXD** (32-bit serial driver) in the **SYSTEM** directory, compared to the original versions of these files from the Windows 9x/Me CD-ROM.

2.

Confirm that the following lines are present in **SYSTEM.INI**:

```
[boot]
comm.drv=comm.drv
[386enh]
device=*vcd
```

The **SERIAL.VXD** driver is not loaded in **SYSTEM.INI**; instead, it is loaded through the Registry.

Windows 2000 and XP use the **SERIAL.SYS** and **SERENUM.SYS** drivers for handling RS-232 devices. You can compare the file sizes and dates for these files to those on the Windows 2000 CD-ROM.

If both drivers are present and accounted for, you can determine whether a particular serial port's I/O address and IRQ settings are properly defined by following these steps for Windows 9x/Me/2000:

1. Right-click the My Computer icon on the desktop and select Properties, or double-click the System icon in the Control Panel. Click the Device Manager tab, click Ports, and then select a specific port (such as COM1).
2. Click the Properties button, and then click the Resources tab to display the current resource settings (IRQ, I/O) for that port.
3. Check the Conflicting Devices List to see whether the port is using resources that conflict with other devices. If the port is in conflict with other devices, click the Change Setting button, and then select a configuration that does not cause resource conflicts. You might need to experiment with these settings until you find the correct one.
4. If the resource settings can't be changed, most likely they must be changed via the BIOS Setup. Shut down and restart the system, enter the BIOS Setup, and change the port configurations there.

◀◀ See "[Resolving Resource Conflicts](#)," p. [393](#).

A common problem with nonPlug and Play modems can occur when people try to use a modem on COM3 with a serial mouse or other device on COM1. Typically, COM1 and COM3 ports use the same IRQ, meaning that they can't be used simultaneously. The COM2 and COM4 ports have the same problem sharing IRQs. If possible, change the COM3 or COM4 port to an IRQ setting that is not in conflict with COM1 or COM2. Note also that some video adapters have an automatic address conflict with COM4.

Advanced Diagnostics Using Loopback Testing

One of the most useful types of diagnostic test is the loopback test, which can be used to ensure the correct function of the serial port and any attached cables. Loopback tests are basically internal (digital) or external (analog). You can run internal tests by simply unplugging any cables from the port and executing the test via a diagnostics program.

The external loopback test is more effective. This test requires that a special loopback connector or wrap plug be attached to the port in question. When the test is run, the port is used to send data out to the loopback plug, which simply routes the data back into the port's receive pins so the port is transmitting and receiving at the same time. A loopback or wrap plug is nothing more than a cable that is doubled back on itself. Most diagnostics programs that run this type of test include the loopback plug, and if not, these types of plugs easily can be purchased or even built.

Following is a list of the wiring necessary to construct your own serial port loopback or wrap plugs:

- *Standard IBM-type 25-pin serial (female DB25S) loopback connector (wrap plug).* Connect the following pins:
 - 1 to 7
 - 2 to 3
 - 4 to 5 to 8
 - 6 to 11 to 20 to 22
 - 15 to 17 to 23
 - 18 to 25
- *Norton Utilities (Symantec) 25-pin serial (female DB25S) loopback connector (wrap plug).* Connect the following pins:
 - 2 to 3
 - 4 to 5
 - 6 to 8 to 20 to 22
- *Standard IBM-type 9-pin serial (female DB9S) loopback connector (wrap plug).* Connect the following pins:
 - 1 to 7 to 8
 - 2 to 3
 - 4 to 6 to 9
- *Norton Utilities (Symantec) 9-pin serial (female DB9S) loopback connector (wrap plug).* Connect the following pins:
 - 2 to 3
 - 7 to 8
 - 1 to 4 to 6 to 9

◀◀ See "[Serial Ports](#)," p. [993](#).

To make these loopback plugs, you need a connector shell with the required pins installed. Then, wire wrap or solder the wires, interconnecting the appropriate pins inside the connector shell as specified in the preceding list.

In most cases, purchasing a set of loopback connectors that are premade is less expensive than making

them yourself. Most companies that sell diagnostics software can also sell you a set of loopback plugs. Some hardware diagnostic programs include loopback plugs with the software.

One advantage of using loopback connectors is that you can plug them into the ends of a cable that is included in the test. This can verify that both the cable and the port are working properly.

If you need to test serial ports further, see [Chapter 22](#), "PC Diagnostics, Testing, and Maintenance," which describes third-party testing software.

Parallel Ports

Parallel ports are normally used for connecting printers to a PC. Even though that was their sole original intention, parallel ports have become much more useful over the years as a more general-purpose, relatively high-speed interface between devices (when compared to serial ports). Today, USB 1.1 compliant ports are almost as fast as parallel ports, and USB 2.0, IEEE 1394a, and IEEE 1394b ports are significantly faster. Originally, parallel ports were one way only; however, modern parallel ports can send and receive data when properly configured.

Parallel ports are so named because they have eight lines for sending all the bits that comprise 1 byte of data simultaneously across eight wires. This interface is fast and traditionally has been used for printers. However, programs that transfer data between systems always have used the parallel port as an option for transmitting data because it can do so 4 bits at a time, rather than 1 bit at a time as with a serial interface.

The following section looks at how these programs transfer data between parallel ports. The only problem with parallel ports is that their cables can't be extended for any great length without amplifying the signal; otherwise, errors occur in the data. [Table 15.11](#) shows the pinout for a standard PC parallel port.

Table 15.11. 25-Pin PC-Compatible Parallel Port Connector

Pin	Description	I/O	Pin	Description	I/O
1	-Strobe	Out	14	-Auto Feed	Out
2	+Data Bit 0	Out	15	-Error	In
3	+Data Bit 1	Out	16	-Initialize Printer	Out
4	+Data Bit 2	Out	17	-Select Input	Out
5	+Data Bit 3	Out	18	-Data Bit 0 Return (GND)	In
6	+Data Bit 4	Out	19	-Data Bit 1 Return (GND)	In
7	+Data Bit 5	Out	20	-Data Bit 2 Return (GND)	In
8	+Data Bit 6	Out	21	-Data Bit 3 Return (GND)	In
9	+Data Bit 7	Out	22	-Data Bit 4 Return (GND)	In
10	-Acknowledge	In	23	-Data Bit 5 Return (GND)	In
11	+Busy	In	24	-Data Bit 6 Return (GND)	In
12	+Paper End	In	25	-Data Bit 7 Return (GND)	In

IEEE 1284 Parallel Port Standard

The IEEE 1284 standard, called Standard Signaling Method for a Bidirectional Parallel Peripheral Interface for Personal Computers, was approved for final release in March 1994. This standard defines the physical characteristics of the parallel port, including data-transfer modes and physical and electrical specifications. IEEE 1284 defines the electrical signaling behavior external to the PC for a multimodal parallel port that can support 4-bit modes of operation. Not all modes are required by the 1284 specification, and the standard makes some provision for additional modes.

The IEEE 1284 specification is targeted at standardizing the behavior between a PC and an attached device, specifically attached printers. However, the specification is also of interest to vendors of parallel port peripherals (removable-media drives, scanners, and so on).

IEEE 1284 pertains only to hardware and line control and does not define how software is to talk to the port. An offshoot of the original 1284 standard has been created to define the software interface. The IEEE 1284.3 committee was formed to develop a standard for software that is used with IEEE 1284-compliant hardware. This standard, designed to address the disparity among providers of parallel port chips, contains a specification for supporting EPP (the Enhanced Parallel Port) mode via the PC's system BIOS.

IEEE 1284 enables much higher throughput in a connection between a computer and a printer or two computers. The result is that the printer cable is no longer the standard printer cable. The IEEE 1284 printer cable uses twisted-pair technology, which results in a much more reliable and error-free connection.

The IEEE 1284 standard also defines the parallel port connectors, including the two preexisting types (called Type A and Type B), as well as an additional high-density Type C connector. Type A refers to the standard DB25 connector used on most PC systems for parallel port connections, whereas Type B refers to the standard 36-pin Centronics-style connector found on most printers. Type C is a high-density 36-pin connector that can be found on some of the newer printers on the market, such as those from HP. The three connectors are shown in [Figure 15.14](#).

Figure 15.14. The three different types of IEEE 1284 parallel port connectors.

[\[View full size image\]](#)

The IEEE 1284 parallel port standard defines five port-operating modes, emphasizing the higher-speed EPP and ECP modes. Some of the modes are input only, whereas others are output only. These five modes combine to create four types of ports, as shown in [Table 15.12](#).

Table 15.12. Types of IEEE 1284 Ports

Parallel Port Type	Input Mode	Output Mode	Comments
SPP (Standard Parallel Port)	Nibble	Compatible	4-bit input, 8-bit output
Bidirectional	Byte	Compatible	8-bit I/O
EPP (Enhanced Parallel Port)	EPP	EPP	8-bit I/O
ECP (Enhanced Capabilities Port)	ECP	ECP	8-bit I/O, uses DMA

The 1284-defined parallel port modes are shown in [Table 15.13](#), which also shows the approximate transfer speeds.

Table 15.13. IEEE 1284 Parallel Port Modes

Parallel Port Mode	Direction	Transfer Rate
Nibble (4-bit)	Input only	50KBps

Byte (8-bit)	Input only	150KBps
Compatible	Output only	150KBps
EPP (Enhanced Parallel Port)	Input/Output	500KBps2.77MBps
ECP (Enhanced Capabilities Port)	Input/Output	500KBps2.77MBps

Each of the port types and modes is discussed in the following sections.

Standard Parallel Ports

Older PCs did not have different types of parallel ports available. The only available port was the parallel port that was used to send information from the computer to a device such as a printer. The unidirectional nature of the original PC parallel port is consistent with its primary use that is, sending data to a printer. There were times, however, when it was desirable to have a bidirectional port for example, when it was necessary to receive feedback from a printer, which was common with PostScript printers. This could not be done easily with the original unidirectional ports.

Although it was never intended to be used for input, a clever scheme was devised in which four of the signal lines can be used as a 4-bit input connection. Thus, these ports can do 8-bit (byte) output (called compatible mode) and 4-bit input (called nibble mode). This is still very common on low-end desktop systems. Systems built after 1993 are likely to have more capable parallel ports, such as bidirectional, EPP, or ECP.

Standard parallel ports are capable of effective transfer rates of about 150KBps output and about 50KBps input.

Bidirectional (8-bit) Parallel Ports

With the introduction of the PS/2 series of machines in 1987, IBM introduced the bidirectional parallel port. These are commonly found in PC-compatible systems today and can be designated "bidirectional," "PS/2 type," or "extended" parallel ports. This port design opened the way for true communication between the computer and the peripheral across the parallel port. This was done by defining a few of the previously unused pins in the parallel connector, and by defining a status bit to indicate in which direction information was traveling across the channel. This allowed for a true 8-bit (called byte mode) input.

These ports can do both 8-bit input and output using the standard eight data lines and are considerably faster than the 4-bit ports when used with external devices. Bidirectional ports are capable of approximately 150KBps transfer rates on both output and input.

Enhanced Parallel Port

EPP is sometimes referred to as the Fast Mode parallel port. Intel, Xircom, and Zenith Data Systems developed and announced the EPP in October 1991. The first products to offer EPP were Zenith Data Systems laptops, Xircom Pocket LAN adapters, and the Intel 82360 SL I/O chip. Currently, almost all systems include a multimode parallel port that supports EPP mode; it's usually built into the Super I/O chip or South Bridge chip on the motherboard.

EPP operates at almost ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals, such as LAN adapters, disk drives, and tape backups. EPP has been included in the IEEE 1284 Parallel Port standard. Transfer rates of up to 2.77MBps are possible with EPP.

Since the original Intel 82360 SL I/O chip in 1992, other major chip vendors (such as National Semiconductor, SMC, Western Digital, and VLSI) have also produced I/O chipsets that offer some form of EPP capability. One problem is that the procedure for enabling EPP across the various chips differs widely from vendor to vendor, and many vendors offer more than one I/O chip.

EPP version 1.7 (March 1992) identifies the first popular version of the hardware specification. With minor changes, this has since been abandoned and folded into the IEEE 1284 standard. Some technical reference materials have erroneously made reference to "EPP specification version 1.9," causing confusion about the EPP standard. Note that "EPP version 1.9" technically does not exist, and any EPP specification after the original version 1.7 is more accurately referred to as a part of the IEEE 1284 specification.

Unfortunately, this has resulted in two somewhat incompatible standards for EPP parallel ports: the original EPP Standards Committee version 1.7 standard and the IEEE 1284 Committee standard, usually called EPP version 1.9. The two standards are similar enough that new peripherals can be designed to support both, but older EPP 1.7 peripherals might not operate with EPP 1284 (EPP 1.9) ports. For this reason, many multimode ports allow configuration in either EPP 1.7 or 1.9 mode, normally selected via the BIOS Setup.

EPP ports are now supported in virtually all Super I/O chips that are used on modern motherboards and in South Bridge chips that integrate I/O functions. Because the EPP port is defined in the IEEE 1284 standard, it also gained software and driver support in Windows 9x/Windows NT on up.

Enhanced Capabilities Port

In 1992, Microsoft and Hewlett-Packard announced the Enhanced Capabilities Port (ECP), another type of high-speed parallel port. Similar to EPP, ECP offers improved performance for the parallel port and requires special hardware logic.

Since the original announcement, ECP is included in IEEE 1284 just like EPP. Unlike EPP, however, ECP is not tailored to support portable PCs' parallel port peripherals; its purpose is to support an inexpensive attachment to a very high-performance printer or scanner. Furthermore, ECP mode requires the use of a DMA channel, which EPP did not define and which can cause troublesome conflicts with other devices that use DMA, such as ISA sound cards or high-performance ISA SCSI host adapters. Most PCs with newer Super I/O chips or integrated South Bridge I/O support can support either EPP or ECP mode.

Most systems today that include a parallel port support ECP's high-throughput communications. In most cases, the ECP can be turned into EPP or standard parallel ports via BIOS. However, it's recommended that the port be placed in ECP mode for the best throughput.

The DMA channel assignment used for ECP mode on a built-in parallel is usually performed through the BIOS setup program, but on some older systems you might need to move a jumper block on the motherboard itself.

Upgrading to EPP/ECP Parallel Ports

If you want to test the parallel ports in a system, especially to determine which type they are, I highly

recommend a utility called Parallel (PARA14.ZIP). This is a handy parallel port information utility that examines your system's parallel ports and reports the port type, I/O address, IRQ level, BIOS name, and an assortment of informative notes and warnings in a compact and easy-to-read display. The output can be redirected to a file for tech support purposes. Parallel uses very sophisticated techniques for port and IRQ detection, and it is aware of a broad range of quirky port features. You can get it from Parallel Technologies (www.lpt.com).

If you have an older system that does not include an EPP/ECP port and you want to upgrade, several companies now offer boards with the correct Super I/O chips to implement these features. I recommend that you check with Parallel Technologies, Byterunner Technologies, Lava Computer Mfg., or SIIG; they are listed in the Vendor List on the disc accompanying this book.

Although USB ports are replacing most nontraditional parallel port uses, high-speed parallel ports such as EPP and ECP are still used for supporting external peripherals, such as Zip drives, CD-ROM drives, scanners, tape drives, and even hard disks. Most of these devices attach to the parallel port using a pass-through connection. This means your local printer can still work through the port, along with the device. The device will have its own drivers that mediate both the communications with the device and the printer pass-through. Using EPP or ECP mode, communications speeds that are as high as 2.77MBps can be achieved. This can enable a relatively high-speed device to function almost as if it were connected to the system bus internally.

Parallel Port Configuration

The configuration of parallel ports is not as complicated as it is for serial ports. Even the original IBM PC had BIOS support for three LPT ports. [Table 15.14](#) shows the standard I/O address and interrupt settings for parallel port use.

Table 15.14. Parallel Interface I/O Port Addresses and Interrupts

Standard LPTx		Alternate LPTx	I/O Ports	IRQ
LPT1			3BC3BFh	IRQ7
LPT1	LPT2		37837Ah	IRQ5
LPT2	LPT3		278h27Ah	IRQ5

Because the BIOS and DOS have always provided three definitions for parallel ports, problems with older systems are infrequent. Problems can arise, however, from the lack of available interrupt-driven ports for ISA/PCI bus systems. Usually, an interrupt-driven port is not absolutely required for printing operations; in fact, many programs do not use the interrupt-driven capability. However, some programs do use the interrupt, such as network print programs and other types of background or spooler-type printer programs.

Also, high-speed laser-printer utility programs often use the interrupt capabilities to enable printing. If you use these types of applications on a port that is not interrupt driven, you see the printing slow to a crawl if it works at all. The only solution is to use an interrupt-driven port. MS-DOS and Windows 9x/Me/2000/XP

now support up to 128 parallel ports.

To configure parallel ports in ISA/PCI bus systems, you normally use the BIOS Setup program for ports that are built into the motherboard, or you might need to set jumpers and switches or use a setup program for adapter-card-based ports. Because each board on the market is different, you always should consult the OEM manual for that particular card if you need to know how the card should be configured.

◀◀ See "[BIOS Hardware/Software](#)," p. [415](#).

Linking Systems with Serial or Parallel Ports

You can connect two systems locally using their serial or parallel ports along with specially wired cables. This form of connection has been used over the years to enable a quick and easy mini-LAN to be set up that allows for the transfer of data between two systems. This can be especially useful when you are migrating your data to a new system you have built or purchased.

Even though using serial or parallel ports to connect two systems to migrate data can be useful, a much better way to connect two systems is to use Ethernet cards and what is commonly called a *crossover* cable. Using this type of connection, you can establish a LAN connection between the two systems and transfer data at the full speed of the Ethernet network, which is 10Mbps, 100Mbps, or 1,000Mbps (1.25MBps, 12.5MBps, or 125MBps). Using serial or parallel ports to transfer data between two systems was more prevalent when most systems did not include some form of network interface card (NIC).

Several free and commercial programs can support serial or parallel-port file transfers. MS-DOS 6.0 and later include a program called Interlink, whereas Windows 95 and later include software called either Direct Cable Connection or Direct Parallel Connection. Other commercially available software includes Laplink.com's LapLink series, Smith Micro's CheckIt FastMove, and Symantec's PC Anywhere, among others.

Serial Port Transfers

Serial ports have always been used for communications between systems, but the ports were usually connected to modems that convert the data to be transmitted over telephone lines, enabling long-distance connections. If the systems were in the same room, you could connect the serial ports directly without using modems by instead using what is commonly referred to as a *null modem cable*. The name comes from the fact that there really aren't any modems present; the cable effectively replaces the modems that would be used at either end. The only drawback is that, because serial ports evolved to support relatively low-speed modem communications, even when using a null modem cable, the connection would be slow because most ports can transmit at 115.2Kbps (14.4KBps).

By using a null modem cable, serial ports can be used to transfer data between systems, although the performance is much lower than when using parallel ports. A serial null modem cable has either a 9-pin or a 25-pin female connector on both ends. The cable should be wired as shown in [Table 15.15](#).

Table 15.15. Serial Null Modem Cable Wiring (9-pin or 25-pin Connectors)

9-Pin	25-Pin	Signal	<-to->	Signal	25-Pin	9-Pin
Pin 5	Pin 7	Ground	<->	Ground	Pin 7	Pin 5
Pin 3	Pin 2	Transmit	<->	Receive	Pin 3	Pin 2
Pin 7	Pin 4	RTS	<->	CTS	Pin 5	Pin 8
Pin 6	Pin 6	DSR	<->	DTR	Pin 20	Pin 4
Pin 2	Pin 3	Receive	<->	Transmit	Pin 2	Pin 3
Pin 8	Pin 5	CTS	<->	RTS	Pin 4	Pin 7
Pin 4	Pin 20	DTR	<->	DSR	Pin 6	Pin 6

If both systems feature infrared serial ports, you can connect the two systems via an infrared connection that uses no cable at all. This type of connection is subject to the limitations of the infrared ports, which allow only very short (a few feet at most) distances with fairly slow data rates.

Because they work so slowly, I usually recommend using serial ports to transfer data between two systems only as a last resort. If possible, you should try to use Ethernet cards and a crossover cable, a USB direct connect cable, or parallel ports with an interlink cable for faster connections.

Parallel Port Transfers

Although the original intention for the parallel port was for it to be used to connect a printer, later implementations allowed for bidirectional data transfer. Bidirectional parallel ports can be used to quickly and easily transfer data between one system and another. If both systems use an EPP/ECP port, you can actually communicate at rates of up to 2.77MBps, which is far faster than the speeds achievable with serial port or infrared (IR) data transfers.

Connecting computers with parallel ports requires a special cable known as a *Direct Cable Connection (DCC)*, *Interlink*, *LapLink*, *parallel crossover*, or *parallel null modem* cable. Many of the commercial file transfer programs provide these cables with their software, or you can purchase them separately from most computer stores or companies that sell cables. However, if you need to make one for yourself, [Table 15.16](#) provides the wiring diagram you need.

Table 15.16. Direct Cable Connection, Interlink, Laplink, or Parallel Null Modem Cable Wiring (25-pin Connectors)

25-Pin	Signal Description	<-to->	Signal Description	25-Pin
Pin 2	Data Bit 0	<->	-Error	Pin 15
Pin 3	Data Bit 1	<->	Select	Pin 13

Pin 4	Data Bit 2	<->	Paper End	Pin 12
Pin 5	Data Bit 3	<->	-Acknowledge	Pin 10
Pin 6	Data Bit 4	<->	Busy	Pin 11
Pin 15	-Error	<->	Data Bit 0	Pin 2
Pin 13	Select	<->	Data Bit 1	Pin 3
Pin 12	Paper End	<->	Data Bit 2	Pin 4
Pin 10	-Acknowledge	<->	Data Bit 3	Pin 5
Pin 11	Busy	<->	Data Bit 4	Pin 6
Pin 25	Ground	<->	Ground	Pin 25

Tip

Even though cables usually are provided for data-transfer programs, notebook users might want to look for an adapter that makes the appropriate changes to a standard parallel printer cable. This can make traveling lighter by preventing the need for additional cables. A DB25 null modem adapter, such as Belkin's F4A602, can be used for this purpose.

Although the prebuilt parallel cables referred to in the previous tip work for connecting two machines with ECP/EPP ports, they can't take advantage of the advanced transfer rates of these ports. Special cables are needed to communicate between ECP/EPP ports. Parallel Technologies is a company that sells ECP/EPP cables for connecting to other ECP/EPP computers, as well as a universal cable for connecting any two parallel ports to use the highest speed.

Windows 9x/Me include a special program called Direct Cable Connection or Direct Parallel Connection, which enables two systems to be networked together via a parallel transfer cable. With Windows 2000 and XP, use the Network Connections dialog box to set up a direct connection. Consult the Windows documentation for information on how to establish a DCC/Direct Parallel connection. Parallel Technologies has been contracted by Microsoft to supply the special DCC cables used to connect the systems, including a special type of cable that uses active electronics to ensure a reliable high-speed interconnection.

Parallel-to-SCSI Converters

Parallel ports can also be used to connect SCSI peripherals to a PC. With a parallel-to-SCSI converter, you can connect any type of SCSI devicesuch as hard disks, CD-ROM drives, tape drives, Zip drives, or scannersto your PC, all via the parallel port. To connect to a SCSI device and also continue to be able to print, most parallel-to-SCSI converters include a pass-through connection for a printer.

Therefore, at one end of the converter is a connection to your parallel port, and at the other end is both SCSI and parallel-port connections. Thus, you can plug in a single SCSI device and still connect your printer as well. The drivers for the parallel-to-SCSI converter automatically pass through any information to the printer, so the printer works normally. Some of these converters handle only one SCSI device, but others can handle up to seven SCSI devices, just as normal SCSI host adapters do. SCSI devices are much slower

when connected to a parallel port than when they are connected to a native SCSI host adapter.

Testing Parallel Ports

Testing parallel ports is, in most cases, simpler than testing serial ports. The procedures are effectively the same as those used for serial ports, except that when you use the diagnostics software, you (obviously) select choices for parallel ports rather than serial ports.

Even though the software tests are similar, the hardware tests require the proper plugs for the loopback tests on the parallel port. Several loopback plugs are required, depending on what software you are using. Most use the IBM-style loopback, but some use the style that originated in the Norton Utilities diagnostics.

You can purchase loopback plugs or build them yourself. The following wiring is needed to construct your own parallel loopback or wrap plugs to test a parallel port:

- *IBM 25-pin parallel (male DB25P) loopback connector (wrap plug).* Connect the following pins:
 - 1 to 13
 - 2 to 15
 - 10 to 16
 - 11 to 17
 - 12 to 14
- *Norton Utilities 25-pin parallel (male DB25P) loopback connector (wrap plug).* Connect the following pins:
 - 2 to 15
 - 3 to 13
 - 4 to 12
 - 5 to 10
 - 6 to 11

Chapter 16. Input Devices

[Wireless Input Devices](#)

Keyboards

One of the most basic system components is the keyboard, which is the primary input device. It is used for entering commands and data into the system. This section looks at the keyboards available for PC-compatible systems, examining the various types of keyboards, how the keyboard functions, the keyboard-to-system interface, and keyboard troubleshooting and repair.

In the years since the introduction of the original IBM PC, IBM has created three keyboard designs for PC systems, and Microsoft has augmented one of them. These designs have become de facto standards in the industry and are shared by virtually all PC manufacturers.

The primary keyboard types are as follows:

- 101-key Enhanced keyboard
- 104-key Windows keyboard
- 83-key PC and XT keyboard (obsolete)
- 84-key AT keyboard (obsolete)

This section discusses the 101-key Enhanced keyboard and the 104-key Windows keyboard, showing the layout and physical appearance of both. Although you can still find old systems that use the 83-key and 84-key designs, these are rare today. Because all new systems today use the 101- or 104-key keyboard design, these versions are covered here.

Note

If you need to learn more about the 83-key PC and XT keyboard or the 84-key AT keyboard, see [Chapter 7](#) of *Upgrading and Repairing PCs, 10th Anniversary Edition*, on the disc included with this book.

Enhanced 101-Key (or 102-Key) Keyboard

In 1986, IBM introduced the "corporate" Enhanced 101-key keyboard for the newer XT and AT models. I use the word *corporate* because this unit first appeared in IBM's RT PC, which was a RISC (reduced instruction set computer) system designed for scientific and engineering applications. Keyboards with this design were soon supplied with virtually every type of system and terminal IBM sold. Other companies quickly copied this design, which became the standard on Intel-based PC systems until the introduction of the 104-key Windows keyboard in 1995 (discussed later in this chapter).

The layout of this universal keyboard was improved over that of the 84-key unit, with perhaps the exception of the Enter key, which reverted to a smaller size. The 101-key Enhanced keyboard was designed to conform to international regulations and specifications for keyboards. In fact, other companies such as Digital Equipment Corporation (DEC) and Texas Instruments (TI) had already been using designs similar to the IBM 101-key unit. The IBM 101-key units originally came in versions with and without the status-indicator LEDs, depending on whether the unit was sold with an XT or AT system. Now many other variations are available from which to choose, including some with integrated pointing devices, such as the IBM TrackPoint II pointing stick, trackballs and touch pads, and programmable keys useful for automating

routine tasks.

The Enhanced keyboard is available in several variations, but all are basically the same electrically and all can be interchanged. IBM with its Lexmark keyboard and printer spinoff and Unicomp (which now produces these keyboards) have produced a number of keyboard models, including versions with built-in pointing devices and new ergonomic layouts. With the replacement of the Baby-AT motherboard and its five-pin DIN (an acronym for Deutsches Institut für Normung e.V.) keyboard connector by ATX motherboards, which use the six-pin mini-DIN keyboard connector, virtually all keyboards on the market today come with cables for the six-pin mini-DIN connector introduced on the IBM PS/2s.

Although the connectors might be physically different, the keyboards are not, and you can either interchange the cables or use a cable adapter to plug one type into the other; some keyboards you can buy at retail include the adapter in the package. See the section "[Keyboard/Mouse Interface Connectors](#)" and [Figure 16.8](#) later in this chapter for the physical and electronic details of these connectors. Many keyboards now include both the standard mini-DIN as well as USB connectors for maximum flexibility when attaching to newer systems. See the section "[USB Keyboards](#)" later in this chapter for details on connecting keyboards via USB.

The 101-key keyboard layout can be divided into the following four sections:

- Typing area
- Numeric keypad
- Cursor and screen controls
- Function keys

The 101-key arrangement is similar to the Selectric keyboard layout, with the exception of the Enter key. The Tab, Caps Lock, Shift, and Backspace keys have a larger striking area and are located in the familiar Selectric locations. Ctrl and Alt keys are on each side of the spacebar, and the typing area and numeric keypad have home-row identifiers for touch typing.

The cursor- and screen-control keys have been separated from the numeric keypad, which is reserved for numeric input. (As with other PC keyboards, you can use the numeric keypad for cursor and screen control when the keyboard is not in Num Lock mode.) A division-sign key (/) and an additional Enter key have been added to the numeric keypad.

The cursor-control keys are arranged in the inverted T format that is now expected on all computer keyboards. The Insert, Delete, Home, End, Page Up, and Page Down keys, located above the dedicated cursor-control keys, are separate from the numeric keypad. The function keys, spaced in groups of four, are located across the top of the keyboard. The keyboard also has two additional function keys: F11 and F12. The Esc key is isolated in the upper-left corner of the keyboard. In addition, dedicated Print Screen/Sys Req, Scroll Lock, and Pause/Break keys are provided for commonly used functions.

Foreign-language versions of the Enhanced keyboard include 102 keys and a slightly different layout from the 101-key U.S. versions.

One of the many useful features of the IBM/Lexmark enhanced keyboard (now manufactured by Unicomp) is removable keycaps. This permits the replacement of broken keys and provides access for easier cleaning. Also, with clear keycaps and paper inserts, you can customize the keyboard. Keyboard templates are also available to provide specific operator instructions.

104-Key (Windows 9x/Me/2000/XP) Keyboard

When Microsoft released Windows 95, it also introduced the Microsoft Natural Keyboard, which implemented a revised keyboard specification that added three new Windows-specific keys to the keyboard.

The Microsoft Windows keyboard specification, which has since become standard for many desktop and laptop keyboards, outlines a set of additional keys and key combinations. The 104-key layout includes left and right Windows keys and an Application key (see [Figure 16.1](#)). These keys are used for operating system and application-level keyboard combinations, similar to the existing Ctrl and Alt combinations. You don't need the new keys to use Windows, but software vendors are adding specific functions to their Windows products that use the new Application key (which provides the same functionality as clicking the right mouse button). The recommended Windows keyboard layout calls for the Left and Right Windows keys (called WIN keys) to flank the Alt keys on each side of the spacebar, as well as an Application key on the right of the Right Windows key. Note that the exact placement of these keys is up to the keyboard designer, so variations exist from keyboard to keyboard.

Figure 16.1. The 104-key Windows keyboard layout.

The WIN keys open the Windows Start menu, which you can then navigate with the cursor keys. The Application key simulates the right mouse button; in most applications, it brings up a context-sensitive pop-up menu. Several WIN key combinations offer preset macro commands as well. For example, you can press WIN+E to launch the Windows Explorer application. [Table 16.1](#) shows a list of all the Windows key combinations used with the 104-key keyboard.

Table 16.1. Windows 9x/Me/2000/XP Key Combinations

Key Combination	Resulting Action
WIN+R	Runs dialog box
WIN+M	Minimize All
Shift+WIN+M	Undo Minimize All
WIN+D	Minimize All or Undo Minimize All
WIN+F1	Help
WIN+E	Starts Windows Explorer
WIN+F	Find Files or Folders
Ctrl+WIN+F	Find Computer
WIN+Tab	Cycles through taskbar buttons
WIN+Break	Displays System Properties dialog box
Application key	Displays a context menu for the selected item

The preceding keystroke combinations work with any manufacturer's 104-key keyboard, but users of certain Microsoft 104-key keyboards can enhance their keyboard use further by installing the IntelliType Pro software supplied by Microsoft with the keyboard.

The Windows and Application keys are not mandatory when running Windows. In fact, preexisting standard key combinations can perform the same functions as these newer keys.

The Windows keyboard specification requires that keyboard makers increase the number of trilograms in their keyboard designs. A *trilogram* is a combination of three rapidly pressed keys that perform a special function, such as Ctrl+Alt+Delete. Designing a keyboard so that the switch matrix correctly registers the additional trilograms plus the additional Windows keys adds somewhat to the cost of these keyboards compared to the previous 101-key standard models.

Many keyboard manufacturers have standardized on 104-key keyboards that include these Windows-specific keys. Some manufacturers have added browser control or other keys that, although not standard, can make them easier to use for navigating web pages and launching various applications.

For additional keyboard combinations you can use, see "Running Windows Without a Mouse" in the Technical Reference section of the disc included with this book.

Laptop Computer Keyboards

One of the biggest influences on keyboard design in recent years has been the proliferation of laptop systems. Because of size limitations, it is obviously impossible to use the standard keyboard layout for a portable computer. Manufacturers have come up with many solutions. Unfortunately, none of these solutions has become an industry standard, as the 101-key layout is. Because of the variations in design, and because a portable system keyboard is not as easily replaceable as that of a desktop system, the keyboard arrangement should be an important part of your purchasing decision.

Early laptop systems often used smaller-than-normal keys to minimize the size of the keyboard, which resulted in many complaints from users. Today, the keytops on portable systems are usually comparable in size to that of a desktop keyboard, although some systems include half-sized keytops for the function keys and other less frequently used keyboard elements. In addition, consumer demand has caused most manufacturers to retain the inverted-T design for the cursor keys after a few abortive attempts at changing their arrangement.

Of course, the most obvious difference in a portable system keyboard is the sacrifice of the numeric keypad. Most systems now embed the keypad into the standard alphabetical part of the keyboard, as shown in [Figure 16.2](#). To switch the keys from their standard values to their keypad values, you typically must press a key combination involving a proprietary function key, often labeled Fn.

Figure 16.2. Most portable systems today embed the numeric keypad into an oddly shaped block of keys on the alphabetical part of the keyboard.

This is an extremely inconvenient solution, and many users abandon their use of the keypad entirely on portable systems. Unfortunately, some activities such as the entry of ASCII codes using the Alt key require the use of the keypad numbers, which can be quite frustrating on systems using this arrangement.

To alleviate this problem, many portable system manufacturers sell external numeric keypads that plug into the external keyboard port, a serial port, or a USB port. This is a great feature for somebody performing a lot of numeric data entry.

In addition to keypad control, the Fn key often is used to trigger other proprietary features in portable systems, such as toggling between an internal and external display and controlling screen brightness and sound volume.

Some portable system manufacturers have gone to great lengths to provide users with adequate keyboards. For a short time, IBM marketed systems with a keyboard that used a "butterfly" design. The keyboard was split into two halves that rested on top of one another when the system was closed. When you opened the lid, the two halves separated to rest side by side, forming a keyboard that was actually larger than the computer case.

Ironically, the trend toward larger-sized displays in portable systems has made this arrangement unnecessary. Many manufacturers have increased the footprint of their laptop computers to accommodate 14.1" and even 15" display panels, leaving more than adequate room for a keyboard with full-size keys. However, even on the newest systems, there still isn't enough room for a separate numeric keypad.

Num Lock

On IBM systems that support the Enhanced keyboard, when the system detects the keyboard on powerup, it enables the Num Lock feature and the light goes on. If the system detects an older 84-key AT-type keyboard, it does not enable the Num Lock function because these keyboards do not have cursor keys separate from the numeric keypad. When the Enhanced keyboards first appeared in 1986, many users (including me) were irritated to find that the numeric keypad was automatically enabled every time the system booted. Most system manufacturers subsequently began integrating a function into the BIOS setup that enabled you to specify the Num Lock status imposed during the boot process.

Some users thought that the automatic enabling of Num Lock was a function of the Enhanced keyboard because none of the earlier keyboards seemed to operate in this way. Remember that this function is not really a keyboard function but instead a function of the motherboard ROM BIOS, which identifies an Enhanced 101-key unit and turns on the Num Lock as a "favor." In systems with a BIOS that can't control the status of the numeric keypad, you can use the DOS 6.0 or higher version **NUMLOCK=** parameter in **CONFIG.SYS** to turn Num Lock on or off, as desired. Some versions of Windows, particularly Windows NT and Windows 2000 (but not Windows XP), disable Num Lock by default.

Keyboard Technology

The technology that makes up a typical PC keyboard is very interesting. This section focuses on all the aspects of keyboard technology and design, including the keyswitches, the interface between the keyboard and the system, the scan codes, and the keyboard connectors.

Keyswitch Design

Today's keyboards use any one of several switch types to create the action for each key. Most keyboards use a variation of the mechanical keyswitch. A mechanical keyswitch relies on a mechanical momentary contact-type switch to make the electrical contact that forms a circuit. Some high-end keyboards use a more sophisticated design that relies on capacitive switches. This section discusses these switches and the highlights of each design.

The most common type of keyswitch is the mechanical type, available in the following variations:

- Pure mechanical
- Foam element
- Rubber dome
- Membrane

Pure Mechanical Switches

The pure mechanical type is just that a simple mechanical switch that features metal contacts in a momentary contact arrangement. The switch often includes a tactile feedback mechanism, consisting of a clip and spring arrangement designed to give a "clicky" feel to the keyboard and offer some resistance to the keypress (see [Figure 16.3](#)).

Figure 16.3. A typical mechanical switch used in older NMB keyboards. As the key is pressed, the switch pushes down on the contacts to make the connection.

Mechanical switches are very durable, usually have self-cleaning contacts, and are normally rated for 20 million keystrokes (which is second only to the capacitive switch in longevity). They also offer excellent tactile feedback.

Despite the tactile feedback and durability provided by mechanical keyswitch keyboards, they have become much less popular than membrane keyboards (discussed later in this chapter). In addition, many companies that produce keyboards that use mechanical keyswitches either use them for only a few of their high-priced models or have phased out their mechanical keyswitch models entirely. With the price of keyboards nose-diving along with other traditional devices, such as mice and drives, the pressure on keyboard makers to cut costs has led many of them to abandon or de-emphasize mechanical-keyswitch designs in favor of the less expensive membrane keyswitch.

The Alps Electric mechanical keyswitch is used by many of the vendors who produce mechanical-switch keyboards, including Alps Electric itself. Other vendors who use mechanical keyswitches for some of their keyboard models include Adesso, Inc. (www.adesso.com), Avant Prime and Stellar (revivals of the classic Northgate keyboards and available from Ergonomic Resources; www.ergo-2000.com), Kinesis (www.kinesis-ergo.com), and SIIG (www.siig.com). Many of these vendors sell through the OEM market, so you must look carefully at the detailed specifications for the keyboard to see whether it is a mechanical keyswitch model.

Foam Element Switches

Foam element mechanical switches were a very popular design in some older keyboards. Most of the older PC keyboards, including models made by Key Tronic and many others, used this technology. These switches are characterized by a foam element with an electrical contact on the bottom. This foam element is mounted on the bottom of a plunger that is attached to the key (see [Figure 16.4](#)).

Figure 16.4. Typical foam element mechanical keyswitch.

When the switch is pressed, a foil conductor on the bottom of the foam element closes a circuit on the printed circuit board below. A return spring pushes the key back up when the pressure is released.

The foam dampens the contact, helping to prevent bounce, but unfortunately it gives these keyboards a "mushy" feel. The big problem with this type of keyswitch design is that little tactile feedback often exists. These types of keyboards send a clicking sound to the system speaker to signify that contact has been made. Preferences in keyboard feel are somewhat subjective; I personally do not favor the foam element switch design.

Another problem with this type of design is that it is more subject to corrosion on the foil conductor and the circuit board traces below. When this happens, the key strikes can become intermittent, which can be frustrating. Fortunately, these keyboards are among the easiest to clean. By disassembling the keyboard completely, you usually can remove the circuit board portion without removing each foam pad separately and expose the bottoms of all the pads. Then, you easily can wipe the corrosion and dirt off the bottoms of the foam pads and the circuit board, thus restoring the keyboard to a "like-new" condition. Unfortunately, over time, the corrosion problem will occur again. I recommend using some Stabilant 22a from D.W. Electrochemicals (www.stabilant.com) to improve the switch contact action and prevent future corrosion. Because of such problems, the foam element design is not used much anymore and has been superseded in popularity by the rubber dome design.

KeyTronicEMS, the most well-known user of this technology, now uses a center-bearing membrane switch technology in its keyboards, so you are likely to encounter foam-switch keyboards only on very old systems.

Rubber Dome Switches

Rubber dome switches are mechanical switches similar to the foam element type but are improved in many ways. Instead of a spring, these switches use a rubber dome that has a carbon button contact on the underside. As you press a key, the key plunger presses on the rubber dome, causing it to resist and then collapse all at once, much like the top of an oil can. As the rubber dome collapses, the user feels the tactile feedback, and the carbon button makes contact between the circuit board traces below. When the key is released, the rubber dome re-forms and pushes the key back up.

The rubber eliminates the need for a spring and provides a reasonable amount of tactile feedback without any special clips or other parts. Rubber dome switches use a carbon button because it resists corrosion and has a self-cleaning action on the metal contacts below. The rubber domes themselves are formed into a sheet that completely protects the contacts below from dirt, dust, and even minor spills. This type of switch design is the simplest, and it uses the fewest parts. This made the rubber dome keyswitch very reliable for several years. However, its relatively poor tactile feedback has led most keyboard manufacturers to switch to the membrane switch design covered in the next section.

Membrane Switches

The membrane keyswitch is a variation on the rubber dome type, using a flat, flexible circuit board to receive input and transmit it to the keyboard microcontroller. Industrial versions of membrane boards use a single sheet for keys that sits on the rubber dome sheet for protection against harsh environments. This arrangement severely limits key travel. For this reason, flat-surface membrane keyboards are not considered usable for normal touch typing. However, they are ideal for use in extremely harsh environments. Because the sheets can be bonded together and sealed from the elements, membrane keyboards can be used in situations in which no other type could survive. Many industrial applications use membrane keyboards for terminals that do not require extensive data entry but are used instead to operate equipment, such as cash registers and point-of-sale terminals in restaurants.

Membrane keyswitches are no longer relegated to fast food or industrial uses, though. Over the last few years, the membrane keyswitch used with conventional keyboard keytops has replaced the rubber dome keyswitch to become the most popular keyswitch used in low-cost to mid-range keyboards. Inexpensive to make, membrane switches have become the overwhelming favorite of low-cost Pacific Rim OEM suppliers and are found in most of the keyboards you'll see at your local computer store or find inside the box of your next complete PC. Although low-end membrane keyswitches have a limited life of only 510 million keystrokes, some of the better models are rated to handle up to 20 million keystrokes, putting them in the range of pure mechanical switches for durability (see [Figure 16.5](#)). A few membrane switches are even more durable: Cherry Corporation's G8x-series keyboards use Cherry's own 50-million-keystroke membrane switch design (www.cherrycorp.com).

Figure 16.5. A typical membrane keyswitch used in NMB keyboards.

Membrane keyboards provide a firmer touch than rubber dome keyboards or the old foam-element keyboards, but they are still no match for mechanical or capacitive keyswitch models in their feel. One interesting exception is the line of keyboards made by KeyTronicEMS using its center-bearing version of membrane keyswitches. Most of its keyboards feature Ergo Technology, which has five levels of force from 35 grams to 80 grams, depending on the relative strength of the fingers used to type various keys. As little as 35 grams of force is required for keys that are used by the little finger, such as Q, Z, and A, and greater levels of force are required for keys used by the other fingers. The spacebar requires the most force: 80 grams. This compares to the standard force level of 55 grams for all keys on normal keyboards (see [Figure 16.6](#)). For more information about keyboards with Ergo Technology, visit the KeyTronicEMS website (www.keytronic.com).

Figure 16.6. Force levels used on KeyTronicEMS keyboards with Ergo Technology.

To find the best membrane keyboards from the vast numbers on the market, look at the lifespan rating of the keyswitches. Longer-lasting keyswitches make the keyboard cost more but will lead to a better experience over the life of the keyboard.

Capacitive Switches

Capacitive switches are technically the only truly nonmechanical keyswitches in use today (see [Figure 16.7](#)). Although the movement of the key and spring is mechanical in nature, these components do not close a mechanical contact or switch. Capacitive switches are much more expensive than the more common rubber dome mechanical membrane switch, but it is more resistant to dirt and corrosion and offers the highest-quality tactile feedback of any type of switch. Consequently, these are the proverbial Cadillac of keyswitches. This type of keyboard is sometimes referred to as a *buckling spring* keyboard because of the coiled spring and rocker used to provide feedback.

Figure 16.7. A capacitive buckling spring keyswitch.

A capacitive switch does not work by making contact between conductors. Instead, two plates usually made of plastic are connected in a switch matrix designed to detect changes in the capacitance of the circuit.

When the key is pressed, the plunger moves the top plate in relation to the fixed bottom plate. Typically, a buckling spring mechanism provides for a distinct over-center tactile feedback with a resounding "click." As the top plate moves, the capacitance between the two plates changes. The comparator circuitry in the keyboard detects this change.

Because this type of switch does not rely on metal contacts, it is nearly immune to corrosion and dirt. These switches are also very resistant to the key bounce problems that result in multiple characters appearing from a single strike. In addition, they are the most durable in the industry rated for 25 million or more keystrokes, as opposed to 1020 million for other designs. The tactile feedback is unsurpassed because the switch provides a relatively loud click and a strong over-center feel. The only drawback to the design is the cost. Capacitive switch keyboards are among the most expensive designs. The quality of the feel and their durability make them worth the price, however.

Originally, the only vendor of capacitive keyswitch keyboards was IBM. Although some of IBM's older keyboards still feature capacitive keyswitches, most current IBM keyboards use rubber-dome or other lower-cost keyswitches. In 1991, IBM spun off its keyboard/printer division as Lexmark, which then spun off the keyboard division as Unicomp in 1996. Today, Unicomp still manufactures and sells "IBM" keyboards with the classic buckling spring capacitive switch ("clickety" as some would say) technology. As a bonus, it also has models with the IBM trackpoint built in. You can purchase new Unicomp (IBM) keyboards direct by calling its toll-free number (800-777-4886) or by visiting its online store (<http://www.pckeyboard.com>).

My personal recommendations are for either the EnduraPro/104 (<http://www.pckeyboard.com/ep104.html>) or the Customizer 101 or 104 (<http://www.pckeyboard.com/customizer.html>). These are brand-new, not reconditioned or rebuilt, keyboards.

The EnduraPro/104 is notable for including a built-in TrackPoint pointing device and a pass-through mini-DIN mouse port, being programmable and reconfigurable, requiring no special drivers, and of course having

the famous buckling spring keyswitches.

Because of the buckling spring capacitive keyswitches (and the resulting clickety feel), I've always been a huge fan of the IBM, Lexmark, and now Unicomp keyboards. In my opinion, they are the absolute best keyboards in the world and the only ones I willingly use on desktop systems. I especially like the fact that they include the IBM TrackPoint because I use a laptop system as my main machine and therefore use only laptops that include the TrackPoint device (mainly IBM, Toshiba, and some Dell/HP/others). The feel and durability of the buckling spring capacitive keyswitches is outstanding, and with the integrated TrackPoint, I never have to move my hands off the keyboard, resulting in much greater efficiency when working with my systems.

The Keyboard Interface

A keyboard consists of a set of switches mounted in a grid or an array called the *key matrix*. When a switch is pressed, a processor in the keyboard identifies which key is pressed by determining which grid location in the matrix shows continuity. The keyboard processor, which also interprets how long the key is pressed, can even handle multiple keypresses at the same time. A 16-byte hardware buffer in the keyboard can handle rapid or multiple keypresses, passing each one to the system in succession.

When you press a key, the contact bounces slightly in most cases, meaning that several rapid on/off cycles occur just as the switch makes contact. This is called *bounce*. The processor in the keyboard is designed to filter this, or *debounce* the keystroke. The keyboard processor must distinguish bounce from a double key strike the keyboard operator intends to make. This is fairly easy, though, because the bouncing is much more rapid than a person could simulate by striking a key quickly several times.

The keyboard in a PC is actually a computer itself. It communicates with the main system in one of two ways:

- Through a special serial data link if a standard PS/2 keyboard connector is used
- Through the USB port

The serial data link used by conventional keyboards transmits and receives data in 11-bit packets of information, consisting of 8 data bits, plus framing and control bits. Although it is indeed a serial link (in that the data flows on one wire), the keyboard interface is incompatible with the standard RS-232 serial port commonly used to connect modems.

The processor in the original PC keyboard was an Intel 8048 microcontroller chip. Newer keyboards often use an 8049 version that has built-in ROM or other microcontroller chips compatible with the 8048 or 8049. For example, in its Enhanced keyboards, IBM has always used a custom version of the Motorola 6805 processor, which is compatible with the Intel chips. The keyboard's built-in processor reads the key matrix, debounces the keypress signals, converts the keypress to the appropriate scan code, and transmits the code to the motherboard. The processors built into the keyboard contain their own RAM, possibly some ROM, and a built-in serial interface.

In the original PC/XT design, the keyboard serial interface is connected to an 8255 Programmable Peripheral Interface (PPI) chip on the motherboard of the PC/XT. This chip is connected to the interrupt controller IRQ1 line, which is used to signal to the system that keyboard data is available. The data is then sent from the 8255 to the processor via I/O port address 60h. The IRQ1 signal causes the main system processor to run a subroutine (INT 9h) that interprets the keyboard scan code data and decides what to do.

In an AT-type keyboard design, the keyboard serial interface is connected to a special keyboard controller

on the motherboard. This controller was an Intel 8042 Universal Peripheral Interface (UPI) slave microcontroller chip in the original AT design. This microcontroller is essentially another processor that has its own 2KB of ROM and 128 bytes of RAM. An 8742 version that uses erasable programmable read-only memory (EPROM) can be erased and reprogrammed. In the past, when you purchased a motherboard ROM upgrade for an older system from a motherboard manufacturer, the upgrade included a new keyboard controller chip as well because it had somewhat dependent and updated ROM code in it. Some older systems might use the 8041 or 8741 chips, which differ only in the amount of built-in ROM or RAM. However, recent systems incorporate the keyboard controller into the main system chipset.

In an AT system, the (8048-type) microcontroller in the keyboard sends data to the (8042-type) keyboard controller on the motherboard. The motherboard-based controller also can send data back to the keyboard. When the keyboard controller on the motherboard receives data from the keyboard, it signals the motherboard with an IRQ1 and sends the data to the main motherboard processor via I/O port address 60h, just as in the PC/XT. Acting as an agent between the keyboard and the main system processor, the 8042-type keyboard controller can translate scan codes and perform several other functions as well. The system also can send data to the 8042 keyboard controller via port 60h, which then passes it on to the keyboard. Additionally, when the system needs to send commands to or read the status of the keyboard controller on the motherboard, it reads or writes through I/O port 64h. These commands usually are followed by data sent back and forth via port 60h.

In older systems, the 8042 keyboard controller is also used by the system to control the A20 memory address line, which provides access to system memory greater than 1MB. More modern motherboards typically incorporate this functionality directly into the motherboard chipset. The AT keyboard connector was renamed the "PS/2" port after the IBM PS/2 family of systems debuted in 1987. That was the time when the connector changed in size from the DIN to the min-DIN, and even though the signals were the same, the mini-DIN version became known from that time forward as the PS/2 port.

Keyboards connected to a USB port work in a surprisingly similar fashion to those connected to conventional DIN or mini-DIN (PS/2) ports after the data reaches the system. Inside the keyboard a variety of custom controller chips is used by various keyboard manufacturers to receive and interpret keyboard data before sending it to the system via the USB port. Some of these chips contain USB hub logic to enable the keyboard to act as a USB hub. After the keyboard data reaches the USB port on the system, the USB port routes the data to the 8042-compatible keyboard controller, where the data is treated as any other keyboard information.

This process works very well after a system has booted into Windows. But what about users who need to use the keyboard at a command prompt or within the BIOS configuration routine? As discussed earlier in this chapter, USB Legacy support must be enabled in the BIOS. A BIOS with USB Legacy support is capable of performing the following tasks:

- Configure the host controller
- Enable a USB keyboard and mouse
- Set up the host controller scheduler
- Route USB keyboard and mouse input to the 8042 Keyboard Controller

Systems with USB Legacy support enabled use the BIOS to control the USB keyboard until a supported operating system is loaded. At that point, the USB host controller driver in the operating system takes control of the keyboard by sending a command called **StopBIOS** to the BIOS routine that was managing the keyboard. When Windows shuts down to MS-DOS, the USB host controller sends a command called **StartBIOS** to restart the BIOS routine that manages the keyboard.

When the BIOS controls the keyboard, after the signals reach the 8042 Keyboard Controller, the USB keyboard is treated just like a conventional keyboard if the BIOS is correctly designed to work with USB

keyboards. As discussed previously in this chapter, a BIOS upgrade might be necessary in some cases to provide proper support of USB keyboards on some systems. The system chipset also must support USB Legacy features.

Typematic Functions

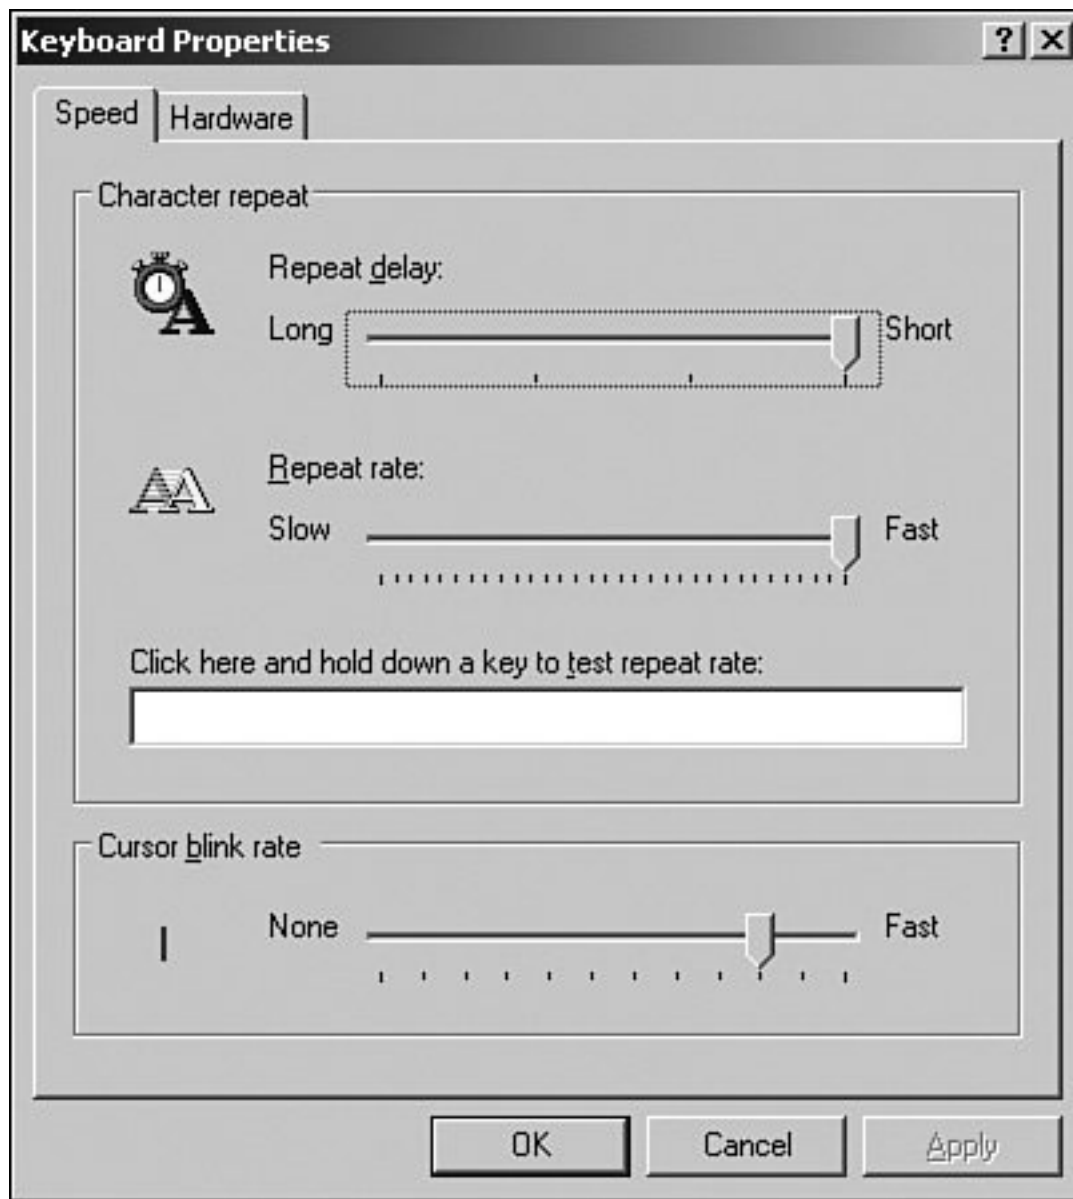

If a key on the keyboard is held down, it becomes *typematic*, which means the keyboard repeatedly sends the keypress code to the motherboard. In the AT-style keyboards, the typematic rate is adjusted by sending the appropriate commands to the keyboard processor. This is impossible for the earlier PC/XT keyboard types because the keyboard interface for these types is not bidirectional.

AT-style keyboards have programmable typematic repeat rate and delay parameters. You can adjust the typematic repeat rate and delay parameters with settings in your system BIOS (although not all BIOS chips can control all functions) or in your operating system. In Windows you use the Keyboard icon in the Control Panel; in DOS you use the **MODE** command. The next section describes how to adjust the keyboard parameters in Windows because this is more convenient than the other methods and enables the user to make further adjustments at any time without restarting the system.

Adjusting Keyboard Parameters in Windows

You can modify the default values for the typematic repeat rate and delay parameters in any version of Windows using the Keyboard icon in the Control Panel. The Repeat Delay slider, shown in [Figure 16.8](#), controls the duration for which a key must be pressed before the character begins to repeat, and the Repeat Rate slider controls how fast the character repeats after the delay has elapsed.

Figure 16.8. Setting the keyboard repeat delay and repeat rate in Windows.

Note

The increments on the Repeat Delay and Repeat Rate sliders in Keyboard Properties in the Control Panel correspond to the timings given for the **MODE** command's **RATE** and **DELAY** values. Each mark in the Repeat Delay slider adds about 0.25 seconds to the delay, and the marks in the Repeat Rate slider are worth about one character per second each.

The dialog box also contains a text box you can use to test the settings you have chosen before committing them to your system. When you click in the box and press a key, the keyboard reacts using the settings currently specified by the sliders, even if you have not yet applied the changes to the Windows environment.

To learn how to adjust keyboard parameters in DOS, see "[Adjusting Keyboard Parameters in DOS](#)" in [Chapter 17](#) of *Upgrading and Repairing PCs, 11th Edition*, which is available in electronic form on the disc included with this book.

Keyboard Key Numbers and Scan Codes

When you press a key on the keyboard, the processor built into the keyboard (8048- or 6805-type) reads the keyswitch location in the keyboard matrix. The processor then sends to the motherboard a serial packet of data containing the scan code for the key that was pressed.

This is called the *Make code*. When the key is released, a corresponding *Break code* is sent, indicating to the motherboard that the key has been released. The Break code is equivalent to the Make scan code plus 80h. For example, if the Make scan code for the "A" key is 1Eh, the Break code would be 9Eh. By using both Make and Break scan codes, the system can determine whether a particular key has been held down and determine whether multiple keys are being pressed.

In motherboards that use an 8042-type keyboard controller, the 8042 chip translates the actual keyboard scan codes into one of up to three sets of system scan codes, which are sent to the main processor. It can be useful in some cases to know what these scan codes are, especially when trouble-shooting keyboard problems or when reading the keyboard or system scan codes directly in software.

When a keyswitch on the keyboard sticks or otherwise fails, the Make scan code of the failed keyswitch usually is reported by diagnostics software, including the power on self test (POST), as well as conventional disk-based diagnostics. This means you must identify the malfunctioning key by its scan code. See the Technical Reference section of the disc included with this book for a comprehensive listing of keyboard key numbers and scan codes for industry-standard 101/102-key (Enhanced) and 104-key Windows keyboards. By looking up the reported scan code on these charts, you can determine which keyswitch is defective or needs to be cleaned.

Note

The 101-key Enhanced keyboards are capable of three scan code sets. Set 1 is the default. Some systems, including some of the IBM PS/2 machines, use one of the other scan code sets during the POST. For example, my IBM P75 uses Scan Code Set 2 during the POST but switches to Set 1 during normal operation. This is rare, and it really threw me off in diagnosing a stuck key problem one time. It is useful to know whether you are having difficulty interpreting the scan code number, however.

IBM also assigns each key a unique key number to distinguish it from the others. This is important when you are trying to identify keys on foreign keyboards that might use symbols or characters different from what the U.S. models do. In the Enhanced keyboard, most foreign models are missing one of the keys (key 29) found on the U.S. version and have two additional keys (keys 42 and 45). This accounts for the 102-key total instead of the 101 keys found on the U.S. version.

Note

See the Technical Reference section of the disc included with this book for a comprehensive listing of keyboard key numbers and scan codes for both the 101/102-key (Enhanced) keyboard and 104-key Windows keyboard, including HID and hotkey scan codes used on the latest USB and hotkey keyboards.

Knowing these key number figures and scan codes can be useful when you are troubleshooting stuck or failed keys on a keyboard. Diagnostics can report the defective keyswitch by the scan code, which varies from keyboard to keyboard on the character it represents and its location.

Many enhanced and USB keyboards now feature hotkeys that either have fixed uses such as opening the default web browser, sending the system into standby mode, and adjusting the speaker volume or are programmable for user-defined functions. Each of these keys also has scan codes. USB keyboards use a special series of codes called Human Interface Device (HID), which are translated into PS/2 scan codes.

International Keyboard Layouts

After the keyboard controller in the system receives the scan codes generated by the keyboard and passes them to the main processor, the operating system converts the codes into the appropriate alphanumeric characters. In the United States, these characters are the letters, numbers, and symbols found on the standard American keyboard.

However, no matter which characters you see on the keytops, adjusting the scan code conversion process to map different characters to the keys is relatively simple. Windows (post 3.x) takes advantage of this capability by enabling you to install multiple keyboard layouts to support various languages.

In Windows 9x/Me, open the Keyboard icon in the Control Panel and select the Language page. The Language box should display the keyboard layout you selected when you installed the operating system. In Windows XP, click the Details button found on the Languages tab in the Regional and Language Options applet (in the Windows Control Panel). By clicking the Add button, you can select any one of several additional keyboard layouts supporting other languages.

These keyboard layouts map various characters to certain keys on the standard keyboard. The standard French layout provides easy access to the accented characters commonly used in that language. For example, pressing the 2 key produces the é character. To type the numeral 2, you press the Shift+2 key combination. Other French-speaking countries have different keyboard conventions for the same characters, so Windows includes support for several keyboard layout variations for some languages, based on nationality.

Note

It is important to understand that this feature is not the same as installing the operating system in a different language. These keyboard layouts do not modify the text already displayed onscreen; they only alter the characters generated when you press certain keys.

The alternative keyboard layouts also do not provide support for non-Roman alphabets, such as Russian and Chinese. The accented characters and other symbols used in languages such as French and German are part of the standard ASCII character set. They are always accessible to English-language users through the Windows Character Map utility or through the use of Alt+keypad combinations. An alternative keyboard layout simply gives you an easier way to access the characters used in certain languages.

If you work on documents using more than one language, you can install as many keyboard layouts as

necessary and switch between them at will. When you click the Enable Indicator on Taskbar check box on the Language page of the Keyboard control panel, a selector appears in the taskbar's tray area that enables you to switch languages easily. On the same page, you can enable a key combination that switches between the installed keyboard layouts.

Keyboard/Mouse Interface Connectors

Keyboards typically have a cable with one of three primary types of connectors at the system end. On most aftermarket keyboards, the cable is connected inside the keyboard case on the keyboard end, requiring you to open the keyboard case to disconnect or test it; different vendors use different connections, making cable interchange between brands of keyboards unlikely. When IBM manufactured its own enhanced keyboards, it used a unique cable assembly that plugged into both the keyboard and the system unit to make cable replacement or interchange easy. Current IBM keyboards, unfortunately, no longer use either the shielded data link (SDL) connector inside the keyboard or the telephone cable-style removable plug-in external keyboard connector used on some more recent models.

Although the method of connecting the keyboard cable to the keyboard can vary, all PC keyboards use one of the following three connectors to attach to the computer:

- *5-pin DIN connector*. Used on most obsolete PC systems with Baby-AT form factor motherboards.
- *6-pin mini-DIN connector*. Often called a *PS/2* connector because it was first used on IBM PS/2 systems, this is the most popular dedicated keyboard and mouse connector.
- *USB connector*. Many newer systems use USB keyboards and mice.

[Figure 16.9](#) and [Table 16.2](#) show the physical layout and pinouts of the respective keyboard connector plugs and sockets (except USB); although the 6-pin SDL connector is not used in this form by most keyboard vendors, most non-IBM keyboards use a somewhat similar connector to attach the keyboard cable to the inside of the keyboard. You can use the pinouts listed in [Table 16.2](#) to test the continuity of each wire in the keyboard connector.

Figure 16.9. Keyboard and mouse connectors.

Table 16.2. Keyboard Connector Signals and Specifications

Signal Name	5-Pin DIN	6-Pin Mini-DIN	6-Pin SDL	Test Voltage
Keyboard Data	2	1	B	+4.8V to +5.5V
Ground	4	3	C	
+5V Power	5	4	E	+2.0V to +5.5V
Keyboard Clock	1	5	D	+2.0V to +5.5V
Not Connected		2	A	
Not Connected		6	F	
Not Connected	3			

DIN = Deutsches Institut für Normung e.V., a committee that sets German dimensional standards.

SDL = Shielded data link, a type of shielded connector created by AMP and used by IBM and others for keyboard cables.

The 6-pin mini-DIN is usually called a PS/2 connector.

PS/2 mouse devices also use the 6-pin mini-DIN connector and have the same pinout and signal descriptions as the keyboard connector; however, the data packets are incompatible. Therefore, you can

easily plug a motherboard mouse (PS/2-style) into a mini-DIN keyboard connector or plug the mini-DIN keyboard connector into a motherboard mouse port. Neither one will work properly in this situation, though.

Caution

I have also seen PCs with external power supplies that used the same standard DIN connectors to attach the keyboard and power supply. Although cross-connecting the mini-DIN connectors of a mouse and keyboard is a harmless annoyance, connecting a power supply to a keyboard socket can be disastrous.

USB keyboards use the Series A USB connector to attach to the USB port built into modern computers. For more information on USB, refer to [Chapter 15](#), "I/O Interfaces from Serial and Parallel to IEEE 1394 and USB."

USB Keyboards

Most keyboards now on the market can connect to the PC via a USB port instead of the standard PS/2 keyboard port. Because USB is a universal bus that uses a hub to enable multiple devices to connect to a single port, a single USB port in a system can replace the standard serial and parallel ports as well as the keyboard and mouse ports. Most current systems and motherboards still include the standard ports (now called *legacy* ports) as well as USB, but most so-called *legacy-free* systems and replacement motherboards have only USB ports for interfacing external devices.

Most keyboard manufacturers now market USB keyboards, but if you want to use your keyboard with both legacy (PS/2) and legacy-free (USB) systems, the most economic way to do so is to specify a keyboard that includes both a USB connector and an adapter to permit the keyboard to work with PS/2 ports. Although Microsoft's Natural Keyboard Elite was the first widely available model to offer USB and PS/2 compatibility, other wired and wireless models from Microsoft, Logitech, Belkin, and others now offer this feature. You can also purchase third-party USB-to-PS/2 adapters, but these can be expensive and might not work with all keyboards.

Not all systems accept USB keyboards, even those with USB ports, because the standard PC BIOS has a keyboard driver that expects a standard keyboard port interface to be present. When a USB keyboard is installed on a system that lacks USB keyboard support, the system can't use it because no driver exists in the BIOS to make it work. In fact, some systems see the lack of a standard keyboard as an error and halt the boot process until one is installed.

To use a keyboard connected via the USB port, you must meet three requirements:

- Have a USB port in the system
- Run Microsoft Windows 98, Windows Me, Windows 2000, or Windows XP (all of which include USB keyboard drivers)
- Have a system chipset and BIOS that feature USB Legacy support

USB Legacy support means your motherboard has a chipset and ROM BIOS drivers that enable a USB keyboard to be used outside the Windows GUI environment. When a system has USB Legacy support enabled, a USB keyboard can be used with MS-DOS (for configuring the system BIOS) when using a command prompt within Windows or when installing Windows on the system for the first time. If USB

Legacy support is not enabled on the system, a USB keyboard will function only when Windows is running.

Most recent systems include USB Legacy support, although it might be disabled by default in the system BIOS.

Also, if the Windows installation fails and requires manipulation outside of Windows, the USB keyboard will not function unless it is supported by the chipset and the BIOS. Almost all 1998 and newer systems with USB ports include a chipset and BIOS with USB Legacy (meaning USB Keyboard) support.

Even though USB Legacy support enables you to use a USB keyboard in almost all situations, don't scrap your standard-port keyboards just yet. Some Windows-related bugs and glitches reported by users include the following:

- *Can't log on to Windows the first time after installing a USB keyboard.* The solution in some cases is to click Cancel when you are asked to log on and then allow the system to detect the keyboard and install drivers. The logon should work normally thereafter. In other cases, you might have to leave the keyboard unplugged when first booting and then plug it in after the OS desktop is up and running. This allows the keyboard to be detected and drivers loaded.
- *Some USB keyboards won't work when the Windows Emergency Boot Disk (EBD) is used to start the system.* The solution is to turn off the system, connect a standard keyboard, and restart the system.
- *Some users of Windows 98 and Windows 98 SE have reported conflicts between Windows and the BIOS when USB Legacy support is enabled on some systems.* This conflict can result in an incapability to detect the USB keyboard if you use the Windows 9x shutdown menu and choose to restart the computer in MS-DOS mode. Check with the system or BIOS vendor for an updated BIOS or a patch to solve this conflict.

If you have problems with Legacy USB support, look at these possible solutions:

- Microsoft's Knowledge Base might address your specific combination of hardware.
- Your keyboard vendor might offer new drivers.
- Your system or motherboard vendor might have a BIOS upgrade you can install.
- Connect the keyboard to the PS/2 port with its adapter (or use a PS/2 keyboard) until you resolve the problem.

See "[Universal Serial Bus](#)," p. [980](#).

Keyboards with Special Features

Several keyboards on the market have special features not found in standard designs. These additional features range from simple things, such as built-in calculators, clocks, and volume control, to more complicated features, such as integrated pointing devices, special character layouts, shapes, and even programmable keys.

Note

In 1936, August Dvorak patented a simplified character layout called the Dvorak Simplified Keyboard (DSK). The Dvorak keyboard was designed to replace the common QWERTY layout used on nearly all keyboards available today. The Dvorak keyboard was approved as an ANSI

standard in 1982 but has seen limited use. For a comparison between the Dvorak keyboard and the common QWERTY keyboard you most likely use, see "The Dvorak Keyboard" in the Technical Reference section of the disc accompanying this book.

Ergonomic Keyboards

A trend that began in the late 1990s is to change the shape of the keyboard instead of altering the character layout. This trend has resulted in several so-called ergonomic designs. The goal is to shape the keyboard to better fit the human hand. The most common of these designs splits the keyboard in the center, bending the sides outward. Some designs allow the angle between the sides to be adjusted, such as the now-discontinued Lexmark Select-Ease, the Goldtouch keyboard designed by Mark Goldstein (who also designed the Select-Ease), and the Kinesis Maxim split keyboards. Others, such as the Microsoft Natural keyboard series, PC Concepts Wave, and Cirque Smooth Cat, are fixed. These split or bent designs more easily conform to the hands' natural angles while typing than the standard keyboard. They can improve productivity and typing speed and help prevent repetitive strain injuries (RSI), such as carpal tunnel syndrome (tendon inflammation). Even more radical keyboard designs are available from some vendors, including models such as the 3-part Comfort and ErgoMagic keyboards, the Kinesis concave contoured keyboard, and others. A good source for highly ergonomic keyboards, pointing devices, and furniture is Ergonomic Resources (www.ergo-2000.com).

Because of their novelty and trendy appeal, some ergonomic keyboards can be considerably more expensive than traditional designs, but for users with medical problems caused or exacerbated by improper positioning of the wrists at the keyboard, they can be an important remedy to a serious problem. General users, however, are highly resistant to change, and these designs have yet to significantly displace the standard keyboard layout. If you don't want to spend big bucks on the more radical ergonomic keyboards but want to give yourself at least limited protection from RSI, consider keyboards with a built-in wrist rest or add a gel-based wrist rest to your current keyboard. These provide hand support without making you learn a modified or brand-new keyboard layout.

USB Keyboards with Hubs

Some of the latest USB keyboards feature a built-in USB hub designed to add two or more USB ports to your system. Even though this sounds like a good idea, keep in mind that a keyboard-based hub won't provide additional power to the USB connectors. Powered hubs work better with a wider variety of devices than unpowered hubs do. I wouldn't choose a particular model based solely on this feature, although if your keyboard has it and your devices work well when plugged into it, that's great. I'd recommend that you use this type of keyboard with your USB mouse or other devices that don't require much power. Bus-powered devices such as scanners and webcams should be connected to a self-powered hub or directly to the USB ports built in to the computer. USB keyboards and mice correspond to the USB 1.1 standard but can also be connected to the faster USB 2.0 ports on the latest systems.

Multimedia and Web-Enabled Keyboards

As I discussed earlier in this chapter, many keyboards sold at retail and bundled with systems today feature fixed-purpose or programmable hotkeys that can launch web browsers, run the Microsoft Media Player, adjust the volume on the speakers, change tracks on the CD player, and so forth. You need Windows 98 or later to use these hotkeys; Windows Me, Windows 2000, and Windows XP add additional support for these keyboards.

For the best results, you should download the latest drivers for your keyboard and version of Windows from the keyboard vendor's website.

Keyboard Troubleshooting and Repair

Keyboard errors are usually caused by two simple problems. Other more difficult, intermittent problems can arise, but they are much less common. The most frequent problems are as follows:

- Defective cables
- Stuck keys

Defective cables are easy to spot if the failure is not intermittent. If the keyboard stops working altogether or every keystroke results in an error or incorrect character, the cable is likely the culprit. Troubleshooting is simple, especially if you have a spare cable on hand. Simply replace the suspected cable with one from a known, working keyboard to verify whether the problem still exists. If it does, the problem must be elsewhere.

If you remove the cable from the keyboard, you can test it for continuity with a digital multimeter (DMM). DMMs that have an audible continuity tester built in make this procedure much easier to perform. To test each wire of the cable, insert the DMM's red pin into the keyboard connector and touch the DMM's black pin to the corresponding wire that attaches to the keyboard's circuit board. Wiggle the ends of the cable as you check each wire to ensure no intermittent connections exist. If you discover a problem with the continuity in one of the wires, replace the cable or the entire keyboard, whichever is cheaper. Because replacement keyboards are so inexpensive, it's almost always cheaper to replace the entire unit than to get a new cable, unless the keyboard is a deluxe model.

For more information about using digital multimeters for testing hardware, see [Chapter 22](#), "PC Diagnostics, Testing, and Maintenance."

Many times you first discover a problem with a keyboard because the system has an error during the POST. Many systems use error codes in a 3xx numeric format to distinguish the keyboard. If you encounter any such errors during the POST, write them down. Some BIOS versions do not use cryptic numeric error codes; they simply state something such as the following:

Keyboard stuck key failure

This message is usually displayed by a system with a Phoenix BIOS if a key is stuck. Unfortunately, the message does not identify which key it is!

If your system displays a 3xx (keyboard) error preceded by a two-digit hexadecimal number, the number is the scan code of a failing or stuck keyswitch. Look up the scan code in the tables provided in the Technical Reference section on the disc to determine which keyswitch is the culprit. By removing the keycap of the offending key and cleaning the switch, you often can solve the problem.

For a simple test of the motherboard keyboard connector, you can check voltages on some of the pins. Using [Figure 16.9](#), which was shown earlier in the chapter, as a guide, measure the voltages on various pins of the keyboard connector. To prevent possible damage to the system or keyboard, turn off the power before disconnecting the keyboard. Then, unplug the keyboard and turn the power back on. Make measurements between the ground pin and the other pins according to [Table 16.2](#), shown earlier in the chapter. If the voltages are within these specifications, the motherboard keyboard circuitry is probably okay.

If your measurements do not match these voltages, the motherboard might be defective. Otherwise, the keyboard cable or keyboard might be defective. If you suspect that the cable is the problem, the easiest thing to do is replace the keyboard cable with a known good one. If the system still does not work normally, you might have to replace the entire keyboard or the motherboard.

In many newer systems, the motherboard's keyboard and mouse connectors are protected by a fuse that can be replaced. Look for any type of fuse on the motherboard in the vicinity of the keyboard or mouse connectors. Other systems might have a socketed keyboard controller chip (8042-type). In that case, you might be able to repair the motherboard keyboard circuit by replacing this chip. Because these chips have ROM code in them, you should get the replacement from the motherboard or BIOS manufacturer. If the motherboard uses a soldered keyboard controller chip or a chipset that integrates the keyboard controller with other I/O chips, you'll need to replace the motherboard.

See the disc included with this book for a listing of the standard POST and diagnostic keyboard error codes used by some systems.

Keyboard Disassembly

Although disassembling a keyboard is possible, most likely you won't need or want to do that given the reasonable prices of keyboards. If you do want to disassemble your keyboard, see "[Keyboard Disassembly](#)" in the Technical Reference section of the disc accompanying this book.

Cleaning a Keyboard

One of the best ways to keep a keyboard in top condition is periodic cleaning. As preventive maintenance, you should vacuum the keyboard weekly, or at least monthly. When vacuuming, you should use a soft brush attachment; this will help dislodge the dust. Also note that many keyboards have keycaps that can come off easily. Be careful when vacuuming; otherwise, you'll have to dig them out of the vacuum cleaner. I recommend using a small, handheld vacuum cleaner made for cleaning computers and sewing machines; these have enough suction to get the job done with little risk of removing your keytops.

You also can use canned compressed air to blow the dust and dirt out instead of using a vacuum. Before you dust a keyboard with the compressed air, turn the keyboard upside down so that the particles of dirt and dust collected inside can fall out.

On all keyboards, each keycap is removable, which can be handy if a key sticks or acts erratically. For example, a common problem is a key that does not work every time you press it. This problem usually results from dirt collecting under the key. An excellent tool for removing keycaps on almost any keyboard is the U-shaped chip puller included in many computer tool kits. Simply slip the hooked ends of the tool under the keycap, squeeze the ends together to grip the underside of the keycap, and lift up. IBM sells a tool designed specifically for removing keycaps from its keyboards, but the chip puller works even better. After removing the cap, spray some compressed air into the space under the cap to dislodge the dirt. Then replace the cap and check the action of the key.

Caution

When you remove the keycaps, be careful not to remove the spacebar on the original 83-key PC and the 84-key AT-type keyboards. This bar is difficult to reinstall. The newer 101-key units use a different wire support that can be removed and replaced much more easily.

When you remove the keycap on some keyboards, you are actually detaching the entire key from the keyswitch. Be careful during the removal or reassembly of the keyboard; otherwise, you'll break the switch. The classic IBM/Lexmark-type keyboards (now made by Unicomp) use a removable keycap that leaves the actual key in place, enabling you to clean under the keycap without the risk of breaking the switches. If your keyboard doesn't have removable keycaps, consider using cleaning wands with soft foam tips to clean beneath the keytops.

Spills can be a problem, too. If you spill a soft drink or cup of coffee into a keyboard, you do not necessarily have a disaster. Many keyboards that use membrane switches are spill resistant. However, you should immediately (or as soon as possible) disconnect the keyboard and flush it out with distilled water. Partially disassemble the keyboard and use the water to wash the components. (See "[Keyboard Disassembly](#)" in the Technical Reference section of the disc accompanying this book for disassembly instructions.) If the spilled liquid has dried, soak the keyboard in some of the water for a while. When you are sure the keyboard is clean, pour another gallon or so of distilled water over it and through the keyswitches to wash away any residual dirt. After the unit dries completely, it should be perfectly functional. You might be surprised to know that drenching your keyboard with water does not harm the components. Just make sure you use distilled water, which is free from residue or mineral content (bottled water is *not* distilled; the distinct taste of many bottled waters comes from the trace minerals they contain!). Also, make sure the keyboard is fully dry before you try to use it; otherwise, some of the components might short out.

Tip

If spills or excessive dust or dirt are expected because of the environment or conditions in which the PC is used, several companies make thin membrane skins that mold over the top of the keyboard, protecting it from liquids, dust, and other contaminants. These skins are generally thin enough so that they don't interfere too much with the typing or action of the keys.

Keyboard Recommendations

In most cases, replacing a keyboard is cheaper or more cost effective than repairing it. This is especially true if the keyboard has an internal malfunction or if one of the keyswitches is defective. Replacement parts for keyboards are almost impossible to procure, and installing any repair part is usually difficult. In addition, many of the keyboards supplied with lower-cost PCs leave much to be desired. They often have a mushy feel, with little or no tactile feedback. A poor keyboard can make using a system a frustrating experience, especially if you are a touch typist. For all these reasons, it is often a good idea to replace an existing keyboard with something better.

Perhaps the highest-quality keyboards in the entire computer industry are those made by IBM, or, more accurately today, Unicomp. Unicomp maintains an extensive selection of more than 1,400 Lexmark and IBM keyboard models and continues to develop and sell a wide variety of traditional and customized models, including keyboards that match the school colors of several universities. Unicomp sells keyboards directly via its website at www.pckeyboard.com. My personal favorite is the black EnduraPro 104.

Note

See the section "Replacement Keyboards" in [Chapter 17](#) of *Upgrading and Repairing PCs, 11th Edition* on this book's disc for a listing of IBM keyboard and cable part numbers.

Some of the classic-design IBM keyboards are available in the retail market under either the IBM or IBM Options brand name. Items under the IBM Options program can be found through the Lenovo Group (www.lenovo.com) or through normal retail channels, such as CompUSA and Computer Discount Warehouse (CDW). These items are also priced much more cheaply than items purchased as spare parts. They include a full warranty and are sold as complete packages, including cables. [Table 16.3](#) lists some of the IBM Options keyboards and part numbers; even though the IBM website no longer offers these models, they can be purchased from various online retailers. Models marked with an * are also available from Unicomp.

Table 16.3. IBM Options Keyboards (Sold Retail)

Description	Part Number
IBM Enhanced keyboard (cable w/DIN plug)	92G7454*
IBM Enhanced keyboard (cable w/mini-DIN plug)	92G7453*
IBM Enhanced keyboard, built-in Trackball (cable w/DIN plug)	92G7456*
IBM Enhanced keyboard, built-in Trackball (cable w/mini-DIN plug)	92G7455*
IBM Enhanced keyboard, integrated TrackPoint II (cables w/mini-DIN plugs)	92G7461*
IBM TrackPoint IV keyboard, Black	01K1260

IBM TrackPoint IV keyboard, White	01K1259
IBM TrackPoint USB Space Saver keyboard (black)	22P5150
IBM USB Keyboard with two-port hub (black)	10K3849
IBM Rapid Access III (black)	22P5185

Keep in mind, though, that because IBM spun off its keyboard business some years ago, many recent and current IBM-labeled keyboards no longer have the distinct feel, quality, or durability found in the older models. Ironically, one of the best ways to get an "IBM" keyboard is to buy the model with the features you want from Unicomp, most of whose keyboards still use the capacitive buckling spring technology IBM originally made famous.

The extremely positive tactile feedback of the IBM/Lexmark/Unicomp design is also a benchmark for the rest of the industry. Although keyboard feel is an issue of personal preference, I have never used a keyboard that feels better than the IBM/Lexmark/Unicomp designs. I now equip every system I use with a Unicomp keyboard, including the many non-IBM systems I use. You can purchase these keyboards directly from Unicomp at very reasonable prices.

Many models are available, including some with a built-in trackball or even the revolutionary TrackPoint pointing device. (TrackPoint refers to a small stick mounted between the G, H, and B keys.) This device was first featured on the IBM ThinkPad laptop systems, although the keyboards are now sold for use on other manufacturers' PCs. The technology is being licensed to many other manufacturers, including Toshiba. Other manufacturers of high-quality keyboards that are similar in feel to the IBM/Lexmark/Unicomp units are Alps, Lite-On, NMB Technologies, and the revived Northgate designs sold under the Avant Prime and Avant Stellar names by Creative Vision Technologies. These keyboards have excellent tactile feedback, with a positive click sound. They are my second choice, after a Unicomp unit.

Pointing Devices

The mouse was invented in 1964 by Douglas Englebart, who at the time was working at the Stanford Research Institute (SRI), a think tank sponsored by Stanford University. The mouse was officially called an X-Y Position Indicator for a Display System. Xerox later applied the mouse to its revolutionary Alto computer system in 1973. At the time, unfortunately, these systems were experimental and used purely for research.

In 1979, several people from Apple including Steve Jobs were invited to see the Alto and the software that ran the system. Steve Jobs was blown away by what he saw as the future of computing, which included the use of the mouse as a pointing device and the graphical user interface (GUI) it operated. Apple promptly incorporated these features into what was to become the Lisa computer and lured away 1520 Xerox scientists to work on the Apple system.

Although Xerox released the Star 8010 computer that used this technology in 1981, it was expensive, poorly marketed, and perhaps way ahead of its time. Apple released the Lisa computer, its first system that used the mouse, in 1983. It was not a runaway success, largely because of its \$10,000 list price, but by then Jobs already had Apple working on the low-cost successor to the Lisa: the Macintosh. The Apple Macintosh was introduced in 1984. Although it was not an immediate hit, the Macintosh has grown in popularity since that time.

Many credit the Macintosh with inventing the mouse and GUI, but as you can see, this technology was actually borrowed from others, including SRI and Xerox. Certainly the Macintosh, and now Microsoft Windows and OS/2, have gone on to popularize this interface and bring it to the legion of Intel-based PC systems.

Although the mouse did not catch on quickly in the PC marketplace, today the GUIs for PC systems, such as Windows, practically demand the use of a mouse. Therefore, virtually every new system sold at retail comes with a mouse. And, because the mice packaged with retail systems are seldom high-quality or up-to-date designs, sooner or later most users are in the market for a better mouse or compatible pointing device.

Mice come in many shapes and sizes from many manufacturers. Some have taken the standard mouse design and turned it upside down, creating the trackball. In the trackball devices, you move the ball with your hand directly rather than moving the unit itself. Trackballs were originally found on arcade video games, such as Missile Command, but have become popular with users who have limited desk space. In most cases, the dedicated trackballs have a much larger ball than would be found on a standard mouse. Other than the orientation and perhaps the size of the ball, a trackball is identical to a mouse in design, basic function, and electrical interface. Like many recent mice, trackballs often come in ergonomic designs, and the more recent models even use the same optical tracking mechanisms used by the latest Microsoft and Logitech mice.

The largest manufacturers of mice are Microsoft and Logitech; these two companies provide designs that inspire the rest of the industry and each other and are popular OEM choices as well as retail brands. Even though mice can come in different varieties, their actual use and care differ very little. The standard mouse consists of several components:

- A housing that you hold in your hand and move around on your desktop
- A method of transmitting movement to the system: either ball/roller or optical sensors
- Buttons (two or more, and often a wheel or toggle switch) for making selections

- An interface for connecting the mouse to the system; conventional mice use a wire and connector, whereas wireless mice use a radio-frequency or infrared transceiver in both the mouse and a separate unit connected to the computer to interface the mouse to the computer

The housing, which is made of plastic, consists of very few moving parts. On top of the housing, where your fingers normally rest, are buttons. There might be any number of buttons, but in the PC world, two is the standard. If your mouse has additional buttons or a wheel, specialized driver software provided by the mouse vendor is required for them to operate to their full potential. Although the latest versions of Windows support scrolling mice, other features supported by the vendor still require installing the vendor's own mouse driver software.

Ball-Type Mice

The bottom of the mouse housing is where the detection mechanisms or electronics are located. On traditional mice, the bottom of the housing contains a small, rubber ball that rolls as you move the mouse across the tabletop. The movements of this rubber ball are translated into electrical signals transmitted to the computer across the cable.

Internally, a ball-driven mouse is very simple, too. The ball usually rests against two rollers: one for translating the x-axis movement and the other for translating the y-axis movement. These rollers are typically connected to small disks with shutters that alternately block and allow the passage of light. Small optical sensors detect movement of the wheels by watching an internal infrared light blink on and off as the shutter wheel rotates and "chops" the light. These blinks are translated into movement along the axes. This type of setup, called an *opto-mechanical mechanism*, is still the most popular type of mouse mechanism (see [Figure 16.10](#)), although optical mice are gaining in popularity. [Figure 16.11](#) shows a PS/2 mouse connector.

Figure 16.10. Typical opto-mechanical mouse mechanism.

[\[View full size image\]](#)

Figure 16.11. Typical PS/2-type mouse connector.

Optical Mice

The other major method of motion detection is optical. Some of the early mice made by Mouse Systems and a few other vendors used a sensor that required a special grid-marked pad. Although these mice were very accurate, the need to use them with a pad caused them to fall out of favor.

Microsoft's IntelliMouse Explorer pioneered the return of optical mice. The IntelliMouse Explorer and the other new-style optical mice from Logitech and other vendors use optical technology to detect movement, and they have no moving parts of their own (except for the scroll wheel and buttons on top). Today's optical mice need no pad; they can work on virtually any surface. This is done by upgrading the optical sensor from the simple type used in older optical mice to a more advanced CCD (charge coupled device). This essentially is a crude version of a video camera sensor that detects movement by seeing the surface move under the mouse. An LED or diode laser is used to provide light for the sensor.

The IntelliMouse Explorer revolutionized the mouse industry; first Logitech, then virtually all other mouse makers, including both retail and OEM suppliers, have moved to optical mice for most of their product lines, offering a wide variety of optical mice in most price ranges. [Figure 16.12](#) shows the essential features of a typical optical mouse.

Figure 16.12. The bottom of the Logitech iFeel optical mouse.

Their versatility and low maintenance (not to mention that neat red or blue glow out the sides!) make optical mice an attractive choice, and the variety of models available from both vendors means you can have the latest optical technology for about the price of a good ball-type mouse. [Figure 16.13](#) shows the interior of a typical optical mouse.

Figure 16.13. The LED inside an optical mouse illuminates the surface by blinking many times per second. The light is reflected from the mousing surface back to the sensor, which converts the information into digital form and sends it to the computer.

All optical mice have a resolution of at least 400dpi and at least one sensor. However, for better performance, some optical mice have improved on these basic features, as listed in [Table 16.4](#).

Table 16.4. Enhanced Optical Mouse Features

Feature	Benefit	Sample Product
800dpi optical resolution	Improves accuracy for mouse positioning	Logitech MX series, Microsoft IntelliMouse Explorer and Optical series
Larger sensor size	Improves tracking on surfaces with repetitive patterns, such as wood desktops	Logitech MX series
Faster tracking speed	Able to keep up with fast hand movements, such as when playing games	Microsoft IntelliMouse Explorer and Optical series
Dual sensors	Faster speed and accuracy, especially for gaming	Logitech MouseMan Dual Optical

Optical mice, similar to traditional ball-type mice, are available as corded or cordless models. Cordless ball-type mice are usually much larger than ordinary mice because of the need to find room for both the bulky ball mechanism and batteries, but cordless optical mice are about the same size as high-end corded mice.

The cable can be any length, but it is typically between 4 and 6 feet long. Mice are also available in a cordless design, which uses either infrared or RF transceivers to replace the cable. A receiver is plugged

into the mouse port, while the battery-powered mouse contains a compatible transmitter.

Tip

If you have a choice on the length of cable to buy, get a longer one. This allows easier placement of the mouse in relation to your computer. Extension cables can be used if necessary.

After the mouse is connected to your computer, it communicates with your system through the use of a device driver, which can be loaded explicitly or built into the operating system software. For example, no separate drivers are necessary to use a mouse with Windows or OS/2, but using the mouse with most DOS-based programs requires a separate driver to be loaded from the **CONFIG.SYS** or **AUTOEXEC.BAT** file. Regardless of whether it is built in, the driver translates the electrical signals sent from the mouse into positional information and indicates the status of the buttons.

The standard mouse drivers in Windows are designed for the traditional two-button mouse or scroll mouse (in Windows Me/2000/XP or later), but increasing numbers of mice feature additional buttons, toggles, or wheels to make them more useful. These additional features require special mouse driver software supplied by the manufacturer.

Pointing Device Interface Types

The connector used to attach your mouse to the system depends on the type of interface you are using. Mice are most commonly connected to your computer through the following interfaces:

- Serial interface (obsolete)
- Dedicated motherboard (PS/2) mouse port
- USB port
- Bluetooth or other wireless connection

Serial

A popular method of connecting a mouse to older PCs is through the standard serial interface. As with other serial devices, the connector on the end of the mouse cable is typically a 9-pin female connector; some very old mice used a 25-pin female connector. Only a couple of pins in the DB-9 or DB-25 connector are used for communications between the mouse and the device driver, but the mouse connector typically has all 9 or 25 pins present.

Because most older PCs come with two serial ports, a serial mouse can be plugged into either COM1 or COM2. The device driver, when initializing, searches the ports to determine to which one the mouse is connected. Some mouse drivers can't function if the serial port is set to COM3 or COM4, but most newer drivers can work with any COM port 14.

Because a serial mouse does not connect to the system directly, it does not use system resources by itself. Instead, the resources are those used by the serial port to which it is connected. For example, if you have a mouse connected to COM2, and if COM2 is using the default IRQ and I/O port address range, both the serial port and the mouse connected to it use IRQ3 and I/O port addresses 2F8h2FFh.

◀◀ See "[Serial Ports](#)," p. [993](#).

Motherboard Mouse Port (PS/2)

Most computers include a dedicated mouse port built into the motherboard. This practice was introduced by IBM with the PS/2 systems in 1987, so this interface is often referred to as a *PS/2 mouse interface*. This term does not imply that such a mouse can work only with a PS/2; instead, it means the mouse can connect to any system that has a dedicated mouse port on the motherboard.

From a hardware perspective, a motherboard mouse connector is usually exactly the same as the mini-DIN connector used for keyboards. In fact, the motherboard mouse port is connected to the 8042-type keyboard controller found on the motherboard. All the PS/2 computers include mini-DIN keyboard and mouse port connectors on the back. Most computers based on the semiproprietary LPX motherboards and all ATX-series motherboards use these same connectors for space reasons. Most Baby-AT motherboards have a pin-header type connector for the mouse port because most standard cases do not have a provision for the mini-DIN mouse connector. If that is the case, an adapter cable is usually supplied with the system. This cable adapts the pin-header connector on the motherboard to the standard mini-DIN type connector used for the motherboard mouse.

Caution

As mentioned in the "[Keyboard/Mouse Interface Connectors](#)" section earlier in this chapter, the mini-DIN sockets used for both keyboard and mouse connections on many systems are physically and electrically interchangeable, but the data packets they carry are not. Be sure to plug each device into the correct socket; otherwise, neither will function correctly. Don't panic if you mix them up, though. They are electrically identical to each other, so you can't damage the ports or the devices.

Connecting a mouse to the built-in mouse port is the best method of connection on systems that don't have USB ports because you do not sacrifice any of the system's interface slots or any serial ports, and the performance is not limited by the serial port circuitry. The standard resource usage for a motherboard (or PS/2) mouse port is IRQ12, as well as I/O port addresses 60h and 64h. Because the motherboard mouse port uses the 8042-type keyboard controller chip, the port addresses are those of this chip. IRQ12 is an interrupt that is usually free on most systems, but if you use a USB mouse, you can probably disable the mouse port to make IRQ12 available for use by another device.

Hybrid Mice

Hybrid mice are those designed to plug into two types of ports. Although a few low-cost mice sold at retail are designed to plug into either the serial port or the PS/2 port, most mice on the retail market today are designed to plug into either the PS/2 port or the USB port. These combination mice are more flexible than the mice typically bundled with systems, which are designed to work only with the PS/2 or USB port to which they attach.

Circuitry in a hybrid mouse automatically detects the type of port to which it is connected and configures the mouse automatically. Serial-PS/2 hybrid mice usually come with a mini-DIN connector on the end of their cable and an adapter that converts the mini-DIN to a 9- or 25-pin serial port connector, although the

reverse is sometimes true on early examples of these mice. PS/2-USB mice usually come with the USB connector on the end of their cable and include a mini-DIN (PS/2) adapter, as shown in [Figure 16.14](#).

Figure 16.14. A typical USB mouse with a PS/2 adapter.

Sometimes people use adapters to try to connect a serial mouse to a motherboard mouse port or a motherboard mouse to a serial port. If this does not work, it is not the fault of the adapter. If the mouse does not explicitly state that it is both a serial and a PS/2-type mouse, it works only on the single interface for which it was designed. Most of the time, you find the designation for which type of mouse you have printed on its underside. A safe rule of thumb to follow is if the mouse didn't come with an adapter or come bundled with a system, it probably won't work with an adapter.

USB

The extremely flexible USB port has become the most popular port to use for mice as well as keyboards and other I/O devices. Compared to the other interfaces, USB mice (and other USB pointing devices such as trackballs) have the following advantages:

- *USB mice move much more smoothly than the traditional PS/2-type.* This is because the frequency with which the mouse reports its position is much higher. A typical PS/2 mouse has a reporting rate of about 40Hz, whereas an average USB-wired mouse has a reporting rate of 125Hz (most USB wireless mice have a reporting rate of 40Hz50Hz). Several utilities are available to test and adjust the mouse frequency.
- *USB mice and pointing devices, similar to all other USB devices, are hot-swappable.* If you like to use a trackball and your computing partners prefer mice, you can just lean over and unplug the other users' pointing device and plug in your own, or move it from PC to PC. You can't do that with

the other port types.

- *USB mice can be attached to a USB hub, such as the hubs contained in some USB keyboards, as well as standalone hubs.* Using a hub makes attaching and removing your mouse easy without crawling around on the floor to reach the back of the computer. Many computers now have front-mounted USB ports, letting you easily attach and remove a USB mouse without the use of an external hub.

Although the early USB mice were decidedly on the premium end of the price scale, low-cost USB mice are now available for as little as \$10. That said, plenty of optical and laser mice are available with premium prices up to \$100 and more.

If you want to use a USB mouse at an MS-DOS prompt, in Windows safe mode, or in some other environment outside of normal Windows 98 or later, make sure that USB Legacy mode is enabled in your PC's BIOS, as discussed earlier in this chapter. Legacy mode enables non-USB-aware systems to recognize a USB keyboard and mouse.

A fourth type of connection, the bus mouse (referred to by Microsoft as the Inport mouse), used a dedicated adapter card and is now obsolete. For more information about the bus mouse, see [Chapter 17](#) of *Upgrading and Repairing PCs, 11th Edition*, which is included on the disc supplied with this book.

Mouse Troubleshooting

If you are experiencing problems with your mouse, you need to look in only two general places: hardware or software. Because mice are basically simple devices, looking at the hardware takes very little time. Detecting and correcting software problems can take a bit longer, however. To troubleshoot wireless mice, see "[Troubleshooting Wireless Input Devices](#)," later in this chapter.

Cleaning Your Mouse

If you notice that the mouse pointer moves across the screen in a jerky fashion, it might be time to clean your mouse. For a mouse with a roller-ball, this jerkiness is caused when dirt and dust become trapped around the mouse's ball-and-roller assembly, thereby restricting its free movement.

From a hardware perspective, the mouse is a simple device, so cleaning it is easy. The first step is to turn the mouse housing over so that you can see the ball on the bottom. Notice that surrounding the ball is an access panel you can open. Sometimes instructions indicate how the panel is to be opened. (Some off-brand mice might require you to remove some screws to get at the roller ball.) Remove the panel to see more of the roller ball and the socket in which it rests.

If you turn the mouse back over, the rubber roller ball should fall into your hand. Take a look at the ball. It might be gray or black, but it should have no visible dirt or other contamination. If it does, wash it in soapy water or a mild solvent, such as contact lens cleaner solution or alcohol, and dry it off.

Now take a look at the socket in which the roller ball normally rests. You will see two or three small wheels or bars against which the ball usually rolls. If you see dust or dirt on or around these wheels or bars, you need to clean them. The best way is to use a compressed air duster, which can blow out any dust or dirt. You also can use some electrical contact cleaner to clean the rollers. Remember, any remaining dirt or dust impedes the movement of the roller ball and results in the mouse not working as it should.

Put the mouse back together by inserting the roller ball into the socket and then securely attaching the

cover panel. The mouse should look just as it did before you removed the panel, except that it will be noticeably cleaner.

One of the major advantages of the new breed of optical mice is the lack of moving parts. Just wipe away dust from the optical sensor, and that's all the cleaning an optical mouse needs.

Interrupt Conflicts

Interrupts are internal signals used by your computer to indicate when something needs to happen. With a mouse, an interrupt is used whenever the mouse has information to send to the mouse driver. If a conflict occurs and the same interrupt used by the mouse is used by a different device, the mouse will not work properly at all.

Interrupt conflicts caused by mice can occur when a serial or PS/2 mouse is used, but not when a USB mouse is used. Mouse ports built in to modern motherboards are almost always set to IRQ12. If your system has a motherboard mouse port, be sure you don't set any other adapter cards to IRQ12; otherwise, a conflict will result.

If you are using a serial mouse, interrupt conflicts typically occur if you add third and fourth serial ports, using either an expansion card or internal serial device, such as a modem. This happens because in ISA bus systems, the odd-numbered serial ports (1 and 3) usually are configured to use the same interrupts as the even-numbered ports (2 and 4) are; IRQ4 is shared by default between COM1 and COM3, and IRQ 2 is shared by default between COM2 and COM4. Therefore, if your mouse is connected to COM2 and an internal modem uses COM4, they both might use the same interrupt, and you can't use them at the same time.

Because the mouse generates interrupts only when it is moved, you might find that the modem functions properly until you touch the mouse, at which point the modem is disconnected. Another example is when your system will run properly until you try to go online with your modem; then the conflict usually locks up the system. You might be able to use the mouse and modem at the same time by moving one of them to a different serial port. For instance, if your mouse uses COM1 and the modem still uses COM4, you can use them both simultaneously because odd and even ports use different interrupts.

The best way around these interrupt conflicts is to make sure no two devices use the same interrupt. Serial port adapters are available for adding COM3 and COM4 serial ports that do not share the interrupts used by COM1 and COM2. These boards enable the new COM ports to use other normally available interrupts, such as IRQs 10, 11, 12, 15, and 5. I never recommend configuring a system with shared ISA interrupts; it is a sure way to run into problems later. However, interrupts used by PCI boards can be shared if you use Windows 95 OSR 2.x, Windows 98, Windows Me, Windows 2000, or Windows XP with recent chipsets that support a feature called IRQ steering.

See "[Interrupts](#)," p. [381](#).

If you suspect an interrupt problem with a bus-type mouse, you can use the Device Manager built into Windows (which is accessible from the System control panel).

See "[Operating System Diagnostics](#)," p. [1304](#).

The Device Manager in Windows 9x/Me/2000/XP is part of the Plug-and-Play (PnP) software for the system, and it is usually 100% accurate on PnP hardware. Although some of these interrupt-reporting programs can have problems, most can easily identify the mouse IRQ if the mouse driver has been loaded. After the IRQ is identified, you might need to change the IRQ setting of the bus mouse adapter or one or more other devices in your system so that everything works together properly.

If your driver refuses to recognize the mouse at all, regardless of its type, try using a different mouse that you know works. Replacing a defective mouse with a known good one might be the only way to know whether the problem is indeed caused by a bad mouse.

I have had problems in which a bad mouse caused the system to lock right as the driver loaded or when third-party diagnostics were being run on the system. If you use a DOS-based diagnostic, such as Microsoft MSD or AMIDIAG, and the system locks up during the mouse test, you have found a problem with either the mouse or the mouse port. Try replacing the mouse to see whether that helps. If it does not, you might need to replace the serial port or bus mouse adapter. If a motherboard-based mouse port goes bad, you can replace the entire motherboard which is usually expensive or you can just disable the motherboard mouse port via jumpers or the system BIOS setup program and install a serial mouse instead. This method enables you to continue using the system without having to replace the motherboard. On systems with Windows 98/Me/2000/XP, you also can switch to a USB mouse, using USB ports on your motherboard or by installing a PCI-based USB card provided your system has a USB port.

Note

To learn more about using the Microsoft MSD diagnostic program to test for mouse or mouse-port problems, see Chapters 17 and 25 of *Upgrading and Repairing PCs, 11th Edition*, which is included on the disc packaged with this book.

Driver Software

Most mice and other pointing devices in use today emulate a Microsoft mouse, enabling you to have basic two-button plus scrolling functions with current versions of Windows without loading any special drivers. However, if your mouse has additional buttons or other special features, you will need to install device-specific drivers available from the mouse vendor.

If you plan to use the mouse from a Windows 9x/Me command prompt or with DOS, you must load the driver manually. To learn more about this process, see "Mouse Driver Software" in the Technical Reference section of the disc packaged with this book.

Scroll Wheels

Late in 1996, Microsoft introduced the IntelliMouse, which differed from standard Microsoft mice by adding a small gray wheel between the mouse buttons. This was the first scrolling mouse, and since then, Logitech, IBM, and virtually all other mouse vendors have made scroll wheels or similar devices standard across almost all models, including OEM mice bundled with computer systems.

The wheel has two main functions. The primary function is to act as a scrolling device, enabling you to scroll through documents or web pages by manipulating the wheel with your index finger. The wheel also

functions as a third mouse button when you press it.

Although three-button mice have been available for years from vendors such as Logitech, the scrolling function provided a real breakthrough. No longer do you have to move the mouse pointer to click the scrollbar on the right side of your screen or take your hand off the mouse to use the arrow keys on the keyboard. You just push or pull on the wheel. This is a major convenience, especially when browsing web pages or working with word processing documents or spreadsheets. Also, unlike three-button mice from other vendors, the IntelliMouse's wheel-button doesn't seem to get in the way and you are less likely to click it by mistake. Although it took a while for software vendors to support the wheel, improvements in application software and Windows support allow today's wheel mice to be fully useful with almost any recent or current Windows program.

Each vendor's mouse driver software offers unique features to enhance the basic operation of the mouse. For example, Logitech's latest MouseWare drivers enable you to select which function the OS should perform when clicking one of the mouse's extra buttons. (The more you spend on a mouse these days, the more buttons it's likely to have.) The drivers also provide various options for how to scroll with each wheel click (three lines, six lines, or one screen). Microsoft's IntelliMouse driver offers a feature called ClickLock, which allows you to drag items without holding down the primary mouse button. In addition, it offers a Universal Scroll feature that adds scrolling mouse support to applications that lack such support. To get the most from whatever scrolling or other advanced-feature mouse you have, be sure you periodically download and install new mouse drivers.

Instead of the wheel used by Microsoft and Logitech, IBM and other mouse vendors frequently use various types of buttons for scrolling. Some inexpensive mice use a rocker switch, but the most elegant of the non-wheel alternatives is IBM's ScrollPoint Pro, which uses a pressure-sensitive scroll stick similar to the TrackPoint pointing device used on IBM's laptop computer and some PC keyboards made by IBM and Unicomp. The scrollpointer in the center of the mouse enables you to smoothly scroll through documents without having to lift your finger to roll the wheel, as you do on the Microsoft version, which makes it much easier and more convenient to use. Because no moving parts exist, the ScrollPoint is also more reliable.

TrackPoint II/III/IV

On October 5, 1992, IBM introduced a revolutionary new pointing device called TrackPoint II as an integrated feature of its new ThinkPad 700 and 700C computers. Often referred to as a *pointing stick device*, TrackPoint II and its successors consist primarily of a small rubber cap that appears on the keyboard right above the B key, between the G and H keys. This was the first significant new pointing device since the mouse had been invented nearly 30 years earlier!

This device occupies no space on a desk, does not have to be adjusted for left-handed or right-handed use, has no moving parts to fail or become dirty, and (most importantly) does not require you to move your hands from the home row to use it. This is an absolute boon for touch typists.

I was fortunate enough to meet the actual creator and designer of this device in early 1992 at the spring Comdex/Windows World in Chicago. He was in a small corner of the IBM booth showing off his custom-made keyboards with a small silicone rubber nub in the middle. In fact, the devices he had were hand-built prototypes installed in standard desktop keyboards, and he was there trying to get public reaction and feedback on his invention. I was invited to play with one of the keyboards, which was connected to a demonstration system. By pressing on the stick with my index finger, I could move the mouse pointer on the screen. The stick itself did not move, so it was not a joystick. Instead, it had a silicone rubber cap that was connected to pressure transducers that measured the amount of force my finger was applying and the direction of the force and moved the mouse pointer accordingly. The harder I pressed, the faster the pointer moved. After playing around with it for just a few minutes, the movements became automaticmost as though I could just think about where I wanted the pointer to go.

The gentleman at the booth turned out to be Ted Selker, the primary inventor of the device. He and Joseph Rutledge created this integrated pointing device at the IBM T.J. Watson Research Center. When I asked him when such keyboards would become available, he could not answer. At the time, there were apparently no plans for production, and he was only trying to test user reaction to the device.

Just over six months later, IBM announced the ThinkPad 700, which included this revolutionary device then called the TrackPoint II Integrated Pointing Device. Since the original version came out, enhanced versions with greater control and sensitivity, called the TrackPoint III and IV, have become available.

Note

The reason the device was called TrackPoint II is that IBM had previously been selling a convertible mouse/trackball device called the TrackPoint. No relationship exists between the original TrackPoint mouse/trackball, which has since been discontinued, and the TrackPoint II integrated device. Since the original TrackPoint II came out, improved versions known as TrackPoint III and TrackPoint IV have become available. In the interest of simplicity, I will refer to all the TrackPoint II, III, and successive devices as just *TrackPoint*.

In its final production form, the TrackPoint consists of a small, red, silicone rubber knob nestled between the G, H, and B keys on the keyboard. The primary and secondary mouse buttons are placed below the spacebar where you can easily reach them with your thumbs without taking your hands off the keyboard.

IBM studies conducted by Selker found that the act of removing your hand from the keyboard to reach for a mouse and replacing the hand on the keyboard takes approximately 1.75 seconds. If you type 60wpm, that can equal nearly two lost words per minute, not including the time lost while you regain your train of thought. Almost all this time can be saved each time you use TrackPoint to move the pointer or make a selection (click or double-click). The combination of the buttons and the positioning knob also enable you to perform drag-and-drop functions easily.

IBM's research also found that people can get up to 20% more work accomplished using the TrackPoint instead of a mouse, especially when the application involves a mix of typing and pointing activities, such as with word processing, spreadsheets, and other typical office applications. In usability tests with the TrackPoint III, IBM gave a group of desktop computer users a TrackPoint and a traditional mouse. After two weeks, 80% of the users had unplugged their mice and switched solely to the TrackPoint device. Selker is convinced (as am I) that the TrackPoint is the best pointing solution for both laptop and desktop systems.

Another feature of the TrackPoint is that a standard mouse can be connected to the system at the same time to enable dual-pointer use. This setup not only enables a single person to use both devices, but also enables two people to use the TrackPoint and the mouse simultaneously to move the pointer on the screen. The first pointing device that moves (thus issuing a system interrupt) takes precedence and retains control over the mouse pointer on the screen until it completes its movement action. The second pointing device is automatically locked out until the primary device is stationary. This enables the use of both devices and prevents each one from interfering with the other.

IBM has added various versions of the TrackPoint to its laptop computers, as well as to high-end keyboards sold under the IBM, Lexmark, and Unicomp names. Laptop computer makers, such as HP and Toshiba, also have licensed the TrackPoint device (Toshiba calls it Accupoint).

I have compared the TrackPoint device to other pointing devices for laptops, such as the trackballs and even the capacitive touch pads, but nothing compares in terms of accuracy and control and, of course, you don't have to take your hands off the keyboard!

Some laptop computer makers copied the TrackPoint instead of licensing it, but with poor results that include sluggish response to input and poor accuracy. One way of telling whether the TrackPoint device is licensed from IBM and uses the IBM technology is if it accepts IBM TrackPoint II/III/IV rubber caps. They have a square hole in them and will properly lock on to any of the licensed versions, such as those found in Toshiba systems.

IBM has upgraded its pointing stick to the TrackPoint III and the current TrackPoint IV. Two main differences exist in the III/IV system, but the most obvious one is in the rubber cap. The IBM TrackPoint II and Toshiba Accupoint caps are made from silicone rubber, which is grippy and works well in most situations. However, if the user has greasy fingers, the textured surface of the rubber can absorb some of the grease and become slippery. Cleaning the cap (and the user's hands) solves the problem, but it can be annoying at times. The TrackPoint III/IV caps are made from a different type of rubber, which Selker calls "plastic sandpaper." This type of cap is much more grippy and does not require cleaning except for cosmetic purposes. I have used both types of caps and can say for certain that the TrackPoint III/IV cap is superior.

Note

Because the Accupoint device used in the Toshiba laptops is licensed from IBM, it uses the same hardware (a pressure transducer called a *strain gauge*) and takes the same physical caps. I ordered a set of the TrackPoint III caps and installed them on my Toshiba portable systems, which dramatically improved the grip. You can get these caps by ordering them from IBM Parts directly or from others who sell IBM parts, such as Compu-Lock (www.compu-lock.com). The cost is less than \$15 for a set of four "plastic sandpaper" red caps.

Replacing the cap is easy: grab the existing cap with your fingers and pull straight up; it pops right off. Then, push on the new red IBM TrackPoint III/IV cap in its place. You will thank me when you feel how you can grip the new IBM cap much more easily than you can grip the designs used by others.

The other difference between the TrackPoint II and III/IV from IBM is in the control software. IBM added routines that implement a subtle technique Selker calls "negative inertia," which is marketed under the label *QuickStop response*. This software not only takes into account how far you push the pointer in any direction, but also how quickly you push or release it. Selker found that this improved software (and the sandpaper cap) enables people to make selections up to 8% faster.

TrackPoint IV includes an extra scroll button, as well as the ability to press the TrackPoint nub to select as if using the left mouse button. These new features make the TrackPoint even better to use.

The bottom line is that anyone who touch types should strongly consider only portable systems that include an IBM-licensed TrackPoint device (such as Toshiba). TrackPoints are far superior to other pointing devices, such as the touch pads, because the TrackPoint is faster to use (you don't have to take your hands off the keyboard's home row), easier to adapt to (especially for speedy touch typists), and far more precise. It takes some getting accustomed to, but the benefits are worth it.

The benefits of the TrackPoint are not limited to portable systems, however. If you use a laptop computer

with TrackPoint like I do, you can have the same features on your desktop keyboard. For desktop systems, I use a Lexmark keyboard with the IBM-licensed TrackPoint device built in. This makes for a more consistent interface between desktop and laptop use because I can use the same pointing device in both environments. You also can buy these keyboards directly from Unicomp (Unicomp keyboards are TrackPoint III compatible); IBM also offers TrackPoint IV in some of its high-end keyboards available at retail.

Mouse and Pointing Stick Alternatives

Because of Windows, many users spend at least as much time moving pointers around the screen as they do in typing, making pointing device choices very important. In addition to the mouse and the pointing stick choices discussed earlier in this chapter, several other popular pointing devices are available, including

- Track pads, such as the Cirque GlidePoint
- Trackballs from many vendors
- Upright mice, such as the 3M Renaissance Mouse

All these devices are treated as mice by the operating system but offer radically different options for the user in terms of comfort. If you're not satisfied with a regular mouse and don't want to use an integrated pointing stick such as the TrackPoint II/III/IV, look into these options.

GlidePoint/Touch Pad

The first touch pad was included on the ill-fated Gavilan portable computer in 1982; however, it didn't catch on until many years later. Cirque originated the modern touch pad (also called a *track pad*) pointing device in 1994. Cirque refers to its technology as the GlidePoint and has licensed the technology to other vendors such as Alps Electric, which also uses the term GlidePoint for its touch pads. The GlidePoint uses a flat, square pad that senses finger position through body capacitance. This is similar to the capacitance-sensitive elevator button controls you sometimes encounter in office buildings or hotels.

When it is used on a portable computer's keyboard, the touch pad is mounted below the spacebar, and it detects pressure applied by your thumbs or fingers. Transducers under the pad convert finger movement into pointer movement. Several laptop manufacturers have licensed this technology from Cirque and have incorporated it into their portable systems. Touch pads are also integrated into a number of mid-range to high-end keyboards from many vendors. When used on a desktop keyboard, touch pads are often offset to the right side of the keyboard's typing area.

Touch pads feature mouse buttons, although the user also can tap or double-tap on the touch pad's surface to activate an onscreen button located under the touch pad's cursor. Dragging and dropping is accomplished without touching the touch pad's buttons; just move the cursor to the object to be dragged, press down on the pad, hold while moving the cursor to the drop point, and raise the finger to drop the object. Some recent models also feature additional hot buttons with functions similar to those on hot-button keyboards, as well a vertical scrollbar on the side and the capability to tap the touch pad to simulate a mouse click.

The primary use for touch pads has been for laptop computer and desktop keyboard-integrated pointing devices, although Cirque and Alps have both sold standalone versions of the touch pad for use as a mouse alternative on desktop systems. Cirque's touch pads are now available at retail under the Fellowes brand name, as well as direct from the Cirque website. The Internet Touchpad (also sold by Fellowes) has enhanced software to support touch gestures, has programmable hot buttons, and includes other features to make web surfing easier.

Although it has gained wide acceptance, especially on portable computers, touch pad technology can have many drawbacks for some users. Operation of the device can be erratic, depending on skin resistance and moisture content. The biggest drawback is that to operate the touch pad, users must remove their hands from the home row on the keyboard, which dramatically slows their progress. In addition, the operation of the touch pad can be imprecise, depending on how pointy your finger or thumb is! On the other hand, if you're not a touch typist, removing your hands from the keyboard to operate the touch pad might be easier than using a TrackPoint. Even with their drawbacks, touch pad pointing devices are still vastly preferable to using a trackball or a cumbersome external mouse with portable systems.

Unless you want to use a "real" mouse with a portable system, I recommend you sit down with portable computers that have both touch pad and TrackPoint pointing devices. Try them yourself for typing, file management, and simple graphics and see which type of integrated pointing device you prefer. I know what I like, but you might have different tastes.

Trackballs

The first trackball I ever saw outside of an arcade was the Wico trackball, a perfect match for mid-1980s video games and computer games, such as Missile Command and others. It emulated the eight-position Atari 2600 analog joystick but was capable of much more flexibility.

Unlike the mid-80s trackballs, today's trackballs are used primarily for business instead of gaming. Most trackballs use a mouse-style positioning mechanism—the differences being that the trackball is on the top or side of the case and is much larger than a mouse ball. The user moves the trackball rather than the input device case, but rollers or wheels inside most models translate the trackball's motion and move a cursor onscreen the same way that mouse rollers or wheels convert the mouse ball's motion into cursor movement.

Trackballs come in a variety of forms, including ergonomic models shaped to fit the (right) hand, ambidextrous models suitable for both lefties and right-handers, optical models that use the same optical sensors found in the latest mice in place of wheels and rollers, and multibutton monsters that look as if they're the result of an encounter with a remote control.

Because they are larger than mice, trackballs lend themselves well to the extra electronics and battery power needed for wireless use. Logitech offers several wireless trackball models that use radio-frequency transceivers; for details of how this technology works, see the section "[Wireless Input Devices](#)," later in this chapter.

Trackballs use the same drivers and connectors as conventional mice. For basic operations, the operating-system-supplied drivers will work, but you should use the latest version of the vendor-supplied drivers to achieve maximum performance with recent models.

Cleaning and Troubleshooting Trackballs

Trackball troubleshooting is similar to mouse troubleshooting. For issues other than cleaning the trackball, see the section "[Mouse Troubleshooting](#)," earlier in this chapter.

Because trackballs are moved by the user's hand rather than by rolling against a tabletop or desktop, they don't need to be cleaned as often as mouse mechanisms do. However, occasional cleaning is recommended, especially with trackballs that use roller movement-detection mechanisms. If the trackball pointer won't move, skips, or drags when you move the trackball, try cleaning the trackball mechanism.

Trackballs can be held into place by a retaining ring, an ejection tab, or simply by gravity. Check the vendor's website for detailed cleaning instructions if your trackball didn't come with such instructions. Swabs and isopropyl alcohol are typically used to clean the trackball and rollers or bearings; see the trackball's instructions for details.

3M's Ergonomic Mouse

Many PC users who grew up using joysticks on the older video games experienced some "interface shock" when they turned in their joysticks for mice. And even long-time mouse users nursing sore arms and elbows have wondered whether the mouse was really as "ergonomic" as it is sometimes claims to be.

3M's solution, developed late in 2000, is to keep the traditional ball-type mouse positioning mechanism but change the user interface away from the hockey puck/soap bar design used for many years to a slanted handle that resembles a joystick. 3M's Ergonomic Mouse (originally called the Renaissance Mouse) is available in two hand sizes and attaches to either the PS/2 port or USB port (serial ports are not supported). The single button on the top of the handle is a rocker switch; push on the left side to left-click and on the right side to right-click. The front handgrip provides scrolling support when the special Ergonomic Mouse driver software is installed.

The Ergonomic Mouse enables the user to hold the pointing device with a "handshake"-style hand and arm position. 3M's website provides detailed ergonomic information to encourage the proper use of the Ergonomic Mouse, which comes with software to support scrolling and other advanced functions. It's available in various colors and separate models for Windows-based PCs and Macs.

Input Devices for Gaming

Originally, game players on the PC used the arrow keys or letter keys on the keyboard to play all types of games. As you can imagine, this limited the number and type of games that could be played on the PC.

Analog Joysticks and the Game Port

As video standards improved, making games more realistic, input devices made especially for game play also became more and more popular. The first joysticks made for the IBM PC were similar to joysticks made for its early rival, the Apple II series. Both the IBM and Apple II joysticks were analog devices that lacked much of the positive feedback game players were accustomed to from the Atari 2600, Commodore 64, or arcade joysticks. These joysticks also required frequent recalibration to work properly and were far from satisfactory to hardcore game players. Also, these devices required their own connectorthe 15-pin game port. The game port found its way onto many sound cards as well as onto multi-I/O cards made for ISA and VL-Bus systems.

Even though joysticks began to add better features, including spring action, video game-style gamepads, and flight control options, the analog nature and slow speed of the gameport began to restrict performance as CPU speeds climbed above 200MHz and high-speed AGP and PCI video cards made ultra-realistic flying, driving, and fighting simulators possible. USB controllers offer the additional speed necessary for more sophisticated gamers.

USB Ports for Gaming

The USB port has become the preferred connector for all types of gaming controllers, including joysticks, gamepads, and steering wheels. Instead of making a single inadequate joystick work for all types of games, users can now interchange controllers using the hot-swap benefits of USB and use the best controller for each type of game.

Although a few low-end game controllers still on the market can connect to either the venerable game port or the serial port, serious gamers want USB because of its higher speed, better support for force feedback (which shakes the game controller realistically to match the action onscreen), and tilting (tilt the gamepad and the onscreen action responds).

As with USB mice, your USB-connected gaming controllers are only as good as their software drivers. Be sure to install the latest software available to keep up with the latest games.

Compatibility Concerns

If you play a lot of older games designed in the heyday of the 15-pin gameport, consider keeping a gameport-type controller. Even though the vendors of USB game controllers strive to make the USB port emulate a game port for use with older games, some older games can't be fooled. If you have problems using a USB game controller with a specific game, check the game's website for patches, as well as your game controller's website for tips and workarounds.

Wireless Input Devices

For several years, many manufacturers have offered cordless versions of mice and keyboards. In most cases, these devices have used either infrared or short-range radio transceivers to attach to standard USB or PS/2 ports, with matching transceivers located inside the mouse or keyboard. Wireless input devices are designed to be easier to use in cramped home-office environments and where a large-screen TV/monitor device is used for home entertainment and computing.

Many manufacturers, including Microsoft, Logitech, and second-tier vendors, offer bundled kits that include a wireless keyboard and mouse which share a transceiver. Because many of these keyboards and mice have the latest features, including programmable keys, multimedia and Internet-access keys, and optical sensors, these wireless combos are often the top-of-the-line products from a given vendor and are often less expensive than buying the keyboard and mouse separately.

How Wireless Input Devices Work

The three major technologies used by wireless input devices are as follows:

- Infrared (IR)
- Proprietary radio frequency
- Bluetooth

All three technologies use a transceiver connected to the PS/2 or USB ports on the computer. Because many wireless transceivers are designed for use with a mouse and keyboard, PS/2-compatible versions have two cablesone for the mouse port and one for the keyboard port. A USB-compatible transceiver needs only one USB port to handle both devices if the system supports USB Legacy (keyboard) functions. The transceiver attached to the computer draws its power from the port.

The transceiver receives signals from the transceiver built in to the mouse or keyboard. These devices require batteries to function; therefore, a common cause of wireless device failure is battery run-down. Early generations of wireless devices used unusual battery types, but most recent products use off-the-shelf alkaline AA or AAA batteries. Many models now use lithium-ion or NiMH rechargeable batteries in which the transceiver connected to the PC also doubles as a charger.

Although all three technologies rely on battery power, the similarities end there. IR devices have a relatively short range (12 ft. maximum) and must have a clear line-of-sight between the input device and transceiver. Anything from a Mountain Dew can to a sheet of paper can block the IR signal from reaching the transceiver, assuming you're aiming the transmitter built in to your input device correctly in the first place. Some late-model IR devices have transceivers that can receive signals through a relatively wide 120° range, but this technology is much more temperamental than the others and has been abandoned by most vendors. [Figure 16.15](#) shows how range and line-of-sight issues can prevent IR input devices from working correctly.

Figure 16.15. A wireless mouse using IR technology must be within range of the transceiver, at the correct angle to the transceiver, and not blocked by any

objects. Otherwise, it cannot work.

- A. Acceptable angle for receiving transmissions
- B. Not acceptable
- C. IR transceiver

- 1. Mouse with IR-connection to transceiver
- 2. Mouse can't connect (out of range)
- 3. Mouse can't connect (line-of-sight blocked)
- 4. Mouse can't connect (wrong angle to transceiver)

Because of the problems with IR devices shown in [Figure 16.15](#), almost all vendors of wireless input devices now use radio waves (RF) for transmission between the device and transceiver. RF-based wireless devices have no line-of-sight problems, but most have a limited range of about 6 ft. from the transmitter (see [Figure 16.16](#)).

Figure 16.16. A wireless mouse using RF must be within range of the transceiver, but unlike IR-based wireless mice, the angle of the mouse to the transceiver doesn't matter and radio signals can't be blocked by books, paper, or other obstacles.

A. Acceptable angle for receiving transmissions (360)
B. RF transceiver

1. Mouse can't connect (out of range)

2. Mouse with connection to RF transceiver

1. Mouse can't connect (out of range)
2. Mouse with connection to RF transceiver

Although RF overcomes line-of-sight issues that can cripple an IR mouse, early versions of RF products had a high potential for interference from other devices and from other devices in use in the same room because of a limited range of channels. For example, early Logitech wireless MouseMan products required the user to manually select the channel used by the transceiver and mouse. If more than six users in a small room had wireless devices, interference was practically inevitable and user error could lead to a user's mouse movements showing up on the wrong computer screen.

Fortunately, improvements in frequency bands used and automatic tuning have enabled all users of a particular type of device to avoid interference with other electronic devices or with each other. For example, many recent wireless products use FastRF technology, which provides 2.5 times the transmission rate of conventional 27MHz devices. The responsiveness of a FastRF connection is all but indistinguishable from a corded mouse or keyboard.

Although the 27MHz frequency pioneered by Logitech's Palomar line of peripherals has become a de facto standard for most recent wireless input devices (it has also been used by Microsoft and IBM for their wireless products), Logitech allows users to enable a digital security feature that uses one of more than 4,000 unique codes to prevent accidentally activating another computer with a wireless device or signal snooping by another user. Most vendors use similar technology, but some might use a much smaller number of codes. The range of 27MHz RF devices is shortabout 6 ft.but the transmitter can be located behind the computer or under the desk without loss of signal.

Finally, there's Bluetooth. Although most wireless products use proprietary radio transceivers, Microsoft, Logitech, and some others have developed wireless mouse and keyboard products using the Bluetooth wireless standard. Bluetooth-enabled devices have an effective range of up to 30 ft. and might be compatible with other brands of devices that are also Bluetooth enabled.

►► For more information about Bluetooth, see [Chapter 18](#), "Local Area Networking," p. [1097](#).

Having used both IR and RF types of wireless devices, I can tell you that a radio-frequency input device beats an infrared input device hands down for use at home or in a small one- or two-person office. It's little wonder that IR-based mouse devices and keyboards are now tough to find on a retail shelf. Today, there is little reason not to opt for an RF device even if you have the choice of purchasing a less-expensive IR peripheral. Because the cost of RF wireless products, including attractive keyboard and mouse combinations, varies widely, RF input devices are affordable for almost everyone. If you're planning to use a computer to drive a big-screen TV or as a presentation unit, consider Bluetooth-enabled devices available from Microsoft, Logitech, and others because of their longer range (up to 10 meters, or 33 ft.).

Power Management Features of Wireless Input Devices

A wireless mouse is useless if its batteries fail, so several vendors of wireless products have developed sophisticated power-management features to help preserve battery lifeespecially with optical mice, which use power-eating LEDs to illuminate the mousing surface. For example, the Logitech Cordless MouseMan Optical's LED sensor has four operating modes, as shown in [Table 16.5](#).

Table 16.5. Logitech Cordless MouseMan Optical Power Management

Mode	LED Flashing Rate	Notes
Normal	1,500 per second	Used only when mouse is being moved across a surface
Glow	1,000 per second	Used when mouse stops moving
Strobe	10 per second	Mouse not moved for more than 2 minutes
Flash	2 per second	Mouse not moved for more than 10 minutes

Wireless keyboards are activated only when you press a key or use the scroll wheel available on some models, so they tend to have longer battery lives than mice. Conventional ball-type mice also have longer battery lives than optical mice, but the convenience and accuracy of optical mice outweigh battery-life issues for most users.

Wireless Pointing Device Issues

Before you invest in wireless pointing devices for multiple computers, you should be aware of the following issues:

- *Line-of-site issues.* Infrared devices won't work if the IR beam between the pointing device and the transceiver attached to the system is blocked. These units are not as suitable for casual in-the-lap use as radio-frequency units are.
- *Radio-frequency interference.* Although early wireless mice used analog tuners that were hard to synchronize, today's wireless input devices typically use digital selectors. However, if several similar devices are used in close quarters, a transceiver might actually receive data from the wrong mouse or keyboard. Also, metal desks and furniture can reduce range and cause erratic cursor movement. Most wireless devices operate around 27MHz, minimizing interference from devices such as cordless phones. If you plan to install several different computers using wireless input devices in the same room, set up one at a time and allow about half an hour between installations if possible to let each unit synchronize with its transceiver. Check with the vendor for other tips on overcoming interference issues.
- *Battery life and availability.* Early wireless devices sometimes used unusual, expensive batteries. Today's units run on common battery types, such as AAA or AA, or even rechargeable batteries. Battery life is usually rated at about 6 months for keyboards or ball-type mice and about 23 months for optical mice. Be sure you have spare batteries for the input device to avoid failures due to running out of battery power. Some vendors provide software that gives users an onscreen warning when batteries run low. Furthermore, when using an optical wireless mouse, you should try working on brighter or whiter surfaces. Many optical mice adjust their sensors based on the illumination of the surface, which is why you might see the light in the mouse change intensity. The less intense the internal LED operates, the less battery power being used.
- *Location.* The range of wireless devices can vary from 6 ft. with conventional RF devices to as much as 30 ft. with Bluetooth-based devices. Consider where the device will be used before making your purchase. For instance, in an office where multiple devices might be used at the same time, a close-range device might be more desirable to avoid crosstalk among devices. On the other hand, the home user who wants to sit away from the screen while maintaining control might want an extended range, making Bluetooth-enabled devices a better choice.
- *User experience.* Different users will have different expectations of wireless input devices, but in

general, the more a wireless input device acts like its wired siblings, the better. The fact that a device is wireless should not compromise its functionality. If things such as reliability, connection, or driver problems hinder proper usage, the device isn't worth using. Hardcore gamers who need the fastest response time possible generally favor the responsiveness of a wired optical mouse over any wireless mouse. Although minimal, some lag time does exist. Some mice can require up to 0.25 centimeter of movement before responding. This lag time can also affect users doing graphical work requiring the superior consistency and accuracy of a wired optical mouse, although the latest dual-sensor wireless optical mice have accuracy on par with wired optical mice.

Troubleshooting Wireless Input Devices

If your wireless input device does not work, check the following:

- *Battery failure.* The transceivers attached to the computer are powered by the computer, but the input devices themselves are battery-powered. Check the battery life suggestions published by the vendor; if your unit isn't running as long as it should, try using a better brand of battery or turning off the device if possible.
- *Lost synchronization between device and transceiver.* Both the device and the transceiver must be using the same frequency to communicate. Depending on the device, you might be able to resynchronize the device and transceiver by pressing a button, or you might need to remove the battery, reinsert the battery, and wait for several minutes to reestablish contact.
- *Interference between units.* Check the transmission range of the transceivers in your wireless units and visit the manufacturer's website for details on how to reduce interference. Typically, you should use different frequencies for wireless devices on adjacent computers.
- *Blocked line of sight.* If you are using infrared wireless devices, check the line of sight carefully at the computer, the space between your device and the computer, and the device itself. You might be dangling a finger or two over the infrared eye and cutting off the signalthe equivalent of putting your finger over the lens on a camera.
- *Serial port IRQ conflicts.* If the wireless mouse is connected to a serial port and it stops working after you install another add-on card, check for conflicts using the Windows Device Manager.
- *Disconnected transceiver.* If you have moved the computer around, you might have disconnected the transceiver from its keyboard, PS/2 mouse, serial, or USB port. You can plug a USB device in without shutting down the system, but the other types require you to shut down, reattach the cable, and restart to work correctly.
- *USB Legacy support not enabled.* If your wireless keyboard uses a transceiver connected to the USB port and the device works in Windows, but not at a command prompt, make sure you have enabled USB Legacy support in the BIOS or use the PS/2 connector from the transceiver to connect to the PS/2 keyboard port.

Relating Internet and LAN Connectivity

Communication between computers is a major part of the PC computing industry. Thanks to the World Wide Web (WWW), no computer user is an island. Whether using a dialup modem or broadband technology, virtually all PCs can be connected to other computers, enabling them to share files, send and receive email, and access the Internet. This chapter explores the various technologies you can use to expand the reach of your PC around the block and around the world.

It might surprise you to see discussions of protocols and networking setup in both this chapter and the LAN chapter of this book, but a modem connection is really just another form of networking. In fact, 32-bit versions of Windows from Windows NT and Windows 9x all the way through Windows XP have all but blended the two services into a single entity.

The reason for this combination is that the typical target for a modem connection has changed over the years. Computer users a decade ago dialed in to *bulletin board systems (BBSs)*, which are proprietary services that provide terminal access to other computers. However, BBSs are practically extinct today. Similarly, proprietary online services such as America Online and CompuServe (now owned by AOL but maintained as a separate service), which have also been around for many years, have almost entirely dropped their proprietary client software and protocols and have been reborn as gateways to the Internet.

With the explosive growth of the Internet, modem and network technologies were joined because both could use the same client software and protocols. Today, the most popular suite of networking protocols TCP/IP is used on both LANs and the Internet. When you dial in to an Internet service provider (ISP), you are actually connecting to a network using a modem instead of a network interface card, and when you use most broadband services, your path to the Internet typically starts with a network interface card, built-in network port, network-to-USB adapter, or even a wireless connection.

Although some new PCs still include a dialup modem, an increasing number of PC users are abandoning dialup Internet access for the faster world of broadband access. In fact, according to the Broadband Update report by eMarketer.com, in 2006 the number of online households in the United States will exceed 51 million. Not bad when you consider that in 1995 no one had a broadband connection in their home and in 2000 only 8.9% of home users had access to broadband. In fact, 2005 marked the first time that the number of broadband users exceeded the number of dialup users both in the United States and worldwide.

Although broadband is growing at a rapid rate and is replacing dialup for the majority of users, dialup connections still have their uses and a large user base. Those without broadband options, those on a budget, or those who travel still need a dialup connection. They can also serve as a valuable backup Internet access source. Even though I use broadband when I can, I still configure new PCs with dialup modems for emergency use when the broadband connection is down. You'll find dialup modem coverage in the second portion of this chapter.

Comparing Broadband and Dialup Modem Internet Access

Even though many new PCs purchased at retail include some type of dialup modem you can use for Internet and email access, you are likely to find that Internet and email access with a dialup modem aren't sufficient for your needs if you use these services for more than a few minutes each day. If you haven't already, here are some reasons you should consider switching to a broadband service:

- *Speed.* The fastest dialup modems can download data at a maximum rate of 56Kbps (limited in the

United States to just 53Kbps by the FCC), whereas broadband services start at 128Kbps for ISDN. Newer forms of broadband, such as DSL and cable modems, start at 384Kbps and typically exceed 500Kbps. Many of the latest services offer 4Mbps8Mbps download speeds. Similarly, broadband services can upload data at several times the speed of a dialup modem.

- *Convenience.* Cable modems and some types of DSL and satellite broadband Internet service are always on, providing you with an immediate connection as soon as you open your web browser or email client. Dialup modems require you to dial up the server and wait up to a minute before you can check your email or surf the Web. Similarly, always-on broadband services can provide you with immediate notification of incoming email, whereas dialup systems can check for incoming email only if you stay online and tie up your phone line.
- *Telephone line usage.* In the wake of the September 11th terrorist attacks on the United States, keeping telephone communications lines open for emergencies has been a major consideration for many people. Most dialup modems do not support call waiting, making it difficult for callers to reach you with important messages while you're online unless you use call-forwarding or call-notification software. Although some dialup ISPs provide software that can alert you to incoming calls, in most cases you must find and install such software yourself. By contrast, most broadband services keep your telephone line free so you can check email or surf the Web and use the telephone at the same time.
- *Price.* One disadvantage of broadband communications is apparent when you see your bill: It costs two to three times as much per month as dialup access with a dialup modem. However, millions of U.S. users believe the additional speed and convenience of broadband make the extra cost of the service per month a worthwhile investment. If you use the Internet enough to justify installing a second phone line just for Internet use, the price gap narrows considerably because you can use most broadband services without tying up your single existing phone line. If you have cable TV, most cable TV providers now also offer cable broadband service and provide a discount off the normal price for customers who have both cable TV and cable Internet service.
- *Ease of reconnection after an operating system upgrade.* Because broadband Internet is usually based on automatically configured TCP/IP network settings, you should be able to keep your broadband connection running during a Windows upgrade with little difficulty. Just verify that you have the correct drivers for your Ethernet adapter (used for most broadband connections) before you perform the upgrade, note your computer and workgroup name, and you should be able to go online as soon as the upgrade is completed. A dialup connection is often much tougher to keep working, especially because of the different methods used by various Windows versions for handling dialup networking.

Broadband Internet Access Types

Thanks to the combination of huge multimegabyte downloads needed to update software and support hardware, dynamic websites with music and full-motion video, and increased demand for online services, even the fastest dialup modem (which can download at just 53Kbps) isn't sufficient for heavy Internet use. More and more users are taking advantage of various types of broadband Internet access solutions, including:

- Cable modem
- DSL
- Fixed-base wireless
- Satellite-based services
- ISDN
- Leased lines

At least one of these services might be available to you, and if you live in a large- to medium-size city, you might be able to choose from two or more of these broadband solutions. The first portion of this chapter focuses on these solutions.

High Speed = Less Freedom

Although high-speed services such as cable modems, DSL, and others all represent major improvements in speed over existing dialup 56Kbps connections, one big drawback you should consider is the loss of freedom in choosing an ISP.

With a 56Kbps dialup modem, you can choose from a wide variety of services, including

- Local ISPs (personalized service)
- National ISPs with dialup access across the country (great for travelers)
- Online services with customized content plus web access (AOL and CompuServe)
- Family-friendly filtered Internet access (Mayberry USA and Lightdog)
- Business-oriented web hosting plus Internet access plans from many vendors

At present, if you want faster speed, you must use the ISP provided with your high-speed service. Whether it's your local telephone company, a third-party vendor, or your friendly cable TV operator, their ISP is your ISP. When you evaluate a high-speed service, remember to look at the special features and services provided by the ISP and its track record for reliability and keeping customers happy. After all, the quality of the work your ISP does is reflected in the quality of your broadband connection.

Tip

If you want the extra speed and convenience of broadband Internet but want to shield your family from some types of Internet content, several filtering services are available that work with your preferred broadband service, including these:

- Cleanweb's Filter Your Internet (FYI) at www.cleanweb.net
- Bsafe Online at <http://www.bsafehome.com>

Cable Modems

For many users, cable modem service, which piggybacks on the same cable TV (CATV) service lines that bring your TV many channels, represents both a big boost in speed from that available with ISDN and a major savings in initial costs and monthly charges. Unlike ISDN, cable modem service normally is sold as an "all you can eat" unlimited-access plan with a modest installation charge (often waived) and a small monthly fee for the rental of the cable modem. Because more and more cable networks support a single standard, you can also choose to buy your cable modem from any of several vendors in some cases, saving even more money over the long term.

Connecting to the Internet with a "Cable Modem"

As with ISDN, the device used to connect a PC to a CATV network is somewhat inaccurately called a modem. In fact, the so-called "cable modem" (a name I will continue to use, for the sake of convenience) is actually a great deal more. The device does indeed modulate and demodulate, but it also functions as a tuner, a network bridge, an encryptor, and an SNMP agent. To connect your PC to a CATV network, you do not use a serial port as with dialup modem technologies or ISDN terminal adapters. Instead, the most typical connection today runs the incoming cable connection to an external cable modem, which has an Ethernet connection to a router, which then connects to 1255 PCs via Ethernet as well. Although you can directly connect most PCs to a cable modem using USB, I do not recommend that option because it precludes using a router. I always recommend running a router between a cable or DSL modem and a PC because a router not only allows more than one PC to be connected, but also provides a robust hardware firewall that helps shield the PCs connected to it from Internet-based attacks. Some cable modems have a built-in router, in which case you don't need to purchase a separate one. If your computer doesn't include an Ethernet adapter built in to the motherboard or a separate Ethernet card, you can install an Ethernet card into an available internal expansion slot or use a USB-based Ethernet adapter instead. Some older cable modem services utilize an internal adapter for one-way service and use the conventional modem for uploads; this type of service is called *telco return* and is largely obsolete. Even though you get fast downloading, telco return systems tie up your phone line and are not recommended.

Tip

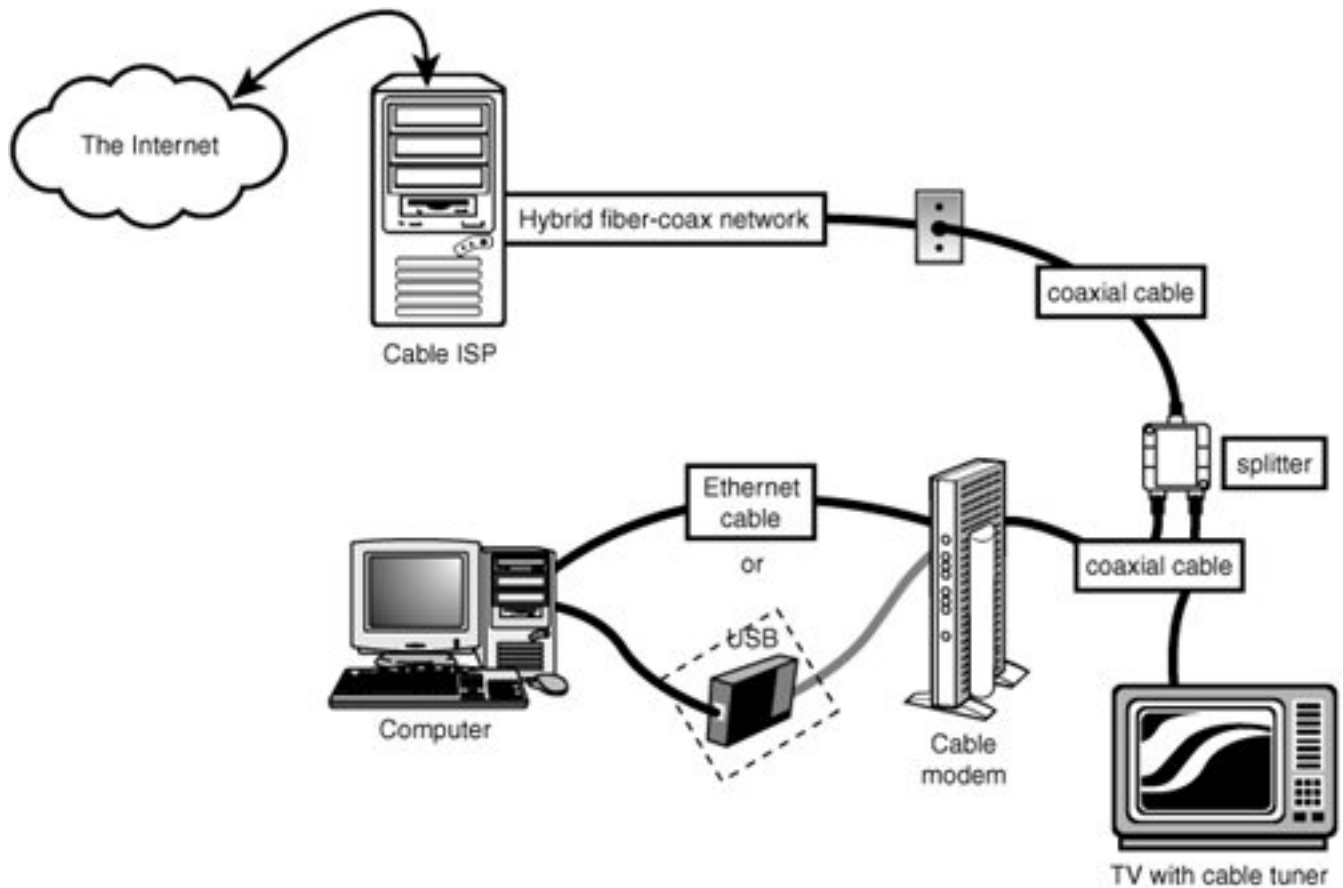

For maximum security, speed, and ease of sharing among multiple systems, I recommend that you connect your cable modem to a router and then connect the router to an Ethernet card or port in your system. Combination cable modems and routers are available that include both functions in one box.

The Cable Modem and the CATV Network

The cable modem connects to the CATV network using the same coaxial cable connection as your cable TV service (see [Figure 17.1](#)). Thus, the cable modem functions as a bridge between the tiny twisted-pair network in your home and the hybrid fiber/coax (HFC) network that connects all the cable customers in your neighborhood.

Figure 17.1. A typical hybrid fiber-coax cable TV network that also includes two-way cable modem service.

[\[View full size image\]](#)

A few cable modem CATV systems have been built using the older one-way (download-only) coax cable, but this type of cable is much slower for cable modem use and is obsolete for both CATV and data communications. The industry has largely replaced coax with HFC. Before you sign up for CATV Internet service, find out which type of service is being offered. Only the two-way, HFC-based systems allow you to use the Internet independently of the telephone system; one-way cable modem service requires a dialup modem for uploading page requests, files, and email. The modem can be built into your one-way cable modem (these are called *bundled* cable modems) or be a separate external dialup modem. In either case, going online with a one-way cable modem ties up your phone line.

Digital CATV service, which brings your TV many more channels and a clearer picture, requires the cable TV provider to upgrade to an HFC physical plant. Thus, digital CATV service is a precursor to two-way cable modem service; pure-coax CATV systems can't be used to transmit digital service or handle two-way cable modem traffic. CATV systems that have been upgraded to digital service are capable of providing two-way cable modem service, after suitable head-end equipment is installed at the CATV central office. A good rule of thumb, therefore, is that CATV systems that don't offer digital cable TV might offer only one-way cable modem service or no cable modem service at all. A typical two-way cable modem connection is shown in [Figure 17.1](#).

Originally, cable modems were not sold to users of CATV Internet access but were leased by the CATV companies offering Internet access to their cable modem customers. This is because each cable modem on a particular CATV network had to match the proprietary technology used by the network. In late 1998, DOCSIS-compliant cable modems began to be used by some CATV companies. DOCSIS refers to devices

that meet the Data Over Cable Service Interface Specification standards established by Cable Television Laboratories, Inc. (CableLabs). Modems that meet DOCSIS standards are now referred to as CableLabs Certified cable modems. Visit the CableLabs website at www.cablelabs.org for a complete list of cable modems that are CableLabs Certified.

Many vendors of traditional modems and other types of communications products, such as 3Com, Motorola, Cisco, D-Link, and many others, now make CableLabs Certified Cable Modemcompliant hardware. The models supported by your CATV Internet provider might vary according to the DOCSIS standard it supports. [Table 17.1](#) provides a brief overview of the differences in these standards.

Table 17.1. DOCSIS Standards Overview

DOCSIS Standard	Benefits	Notes
1.0	Basic broadband CATV (cable modem) service	Original DOCSIS version
1.1	Supports tiered service (different speeds at different costs), faster uploading, home networking, and packet telephony while reducing costs	Backward-compatible with DOCSIS 1.0
2.0	Faster performance for downloading and uploading compared to DOCSIS 1.0 and 1.1; supports high-speed two-way business services	Backward-compatible with DOCSIS 1.1, 1.0

Although most cable modems are now available for about \$50\$100, compared to \$10\$65 for typical dialup modems, you should check with your CATV Internet provider before purchasing one to determine which models are supported by your provider and whether your CATV Internet provider still requires you to lease the cable modem.

If you plan to keep cable modem service for more than a year, I recommend purchasing a CableLabs Certified cable modem, but if you're unsure of your long-term plans, leasing isn't all that expensive. Typical lease costs for the device add only about \$10/month to the monthly rate of \$30\$45 for cable modem service.

Cable modems come in several forms:

- *External cable modem "box."* It requires an Ethernet NIC or a USB port. Some vendors provide "bundles" that combine the external cable modem with the NIC at a lower price than leasing or purchasing both separately. This type of cable modem is designed for fast uploads as well as fast downloads and works only on newer "two-way" CATV Internet connections. Almost all cable modems sold by retailers fall into this category.
- *Internal cable modem with a 56Kbps dialup modem built in.* This type of cable modem provides fast downloads but uploads at dialup speeds only; this type might use either an ISA or a PCI slot.
- *Internal cable modem for use with a separate 56Kbps dialup modem.* This type might use either an ISA or a PCI slot. As with the previous model, uploads are at dialup speeds only.

- *Internal cable modem for use with two-way service.* This type of cable modem is rare, but because some internal cable modems are now CableLabs Certified, you might see some cable ISPs offer these. Some also might be designed for one-way service, enabling the cable ISP to install a single modem for use with both types of service.
- *External cable modem with a 56Kbps dialup modem built in.* This type of cable modem is sometimes designed to work with both one-way and two-way services.

Cable modem models that must be used with (or include) a dialup modem are designed for older "one-way" CATV Internet connections; these will tie up your phone line when transmitting page requests as well as when sending uploads.

CATV Bandwidth

Cable TV uses what is known as a *broadband network*, meaning the bandwidth of the connection is split to simultaneously carry many signals at different frequencies. These signals correspond to the channels you see on your TV. A typical HFC network provides approximately 750MHz of bandwidth, and each channel requires 6MHz. Therefore, because the television channels start at about 50MHz, you would find channel 2 in the 50MHz-56MHz range, channel 3 at 57MHz-63MHz, and so on up the frequency spectrum. At this rate, an HFC network can support about 110 channels.

For data networking purposes, cable systems typically allocate one channel's worth of bandwidth in the 50MHz-750MHz range for downstream traffic—that is, traffic coming into the cable modem from the CATV network. In this way, the cable modem functions as a tuner, just like your cable TV box, ensuring that your PC receives signals from the correct frequency.

Upstream traffic (data sent from your PC to the network) uses a different channel. Cable TV systems commonly reserve the bandwidth from 5MHz to 42MHz for upstream signals of various types (such as those generated by cable TV boxes that enable you to order pay-per-view programming). Depending on the bandwidth available, you might find that your CATV provider does not furnish the same high speed upstream as it does downstream. This is called an *asymmetrical network*.

Note

Because the upstream speed often does not match the downstream speed (and to minimize noise, which tends to accumulate because of the tree-and-branch nature of the network), cable TV connections usually are not practical for hosting web servers and other Internet services. This is largely deliberate because most CATV providers are currently targeting their traditional home user market. As the technology matures, however, this type of Internet connection is likely to spread to the business world as well. There are now specialized domain name services that can be used to "point" web surfers to your cable modem or DSL connection.

Some cable ISPs require you to switch to a more expensive business plan if you want to host a server (including a P2P server such as Gnutella) on your cable modem connection. In fact, hosting a server on a residential cable modem service could be a violation of your contract and could lead to cancellation of your service.

The amount of data throughput that the single 6MHz downstream channel can support depends on the type of modulation used at the head end (that is, the system to which your PC connects over the network). Using a technology called 64 QAM (quadrature amplitude modulation), the channel might be capable of

carrying up to 27Mbps of downstream data. A variant called 256 QAM can boost this to 36Mbps.

You must realize, however, that you will not achieve anything even approaching this throughput on your PC. First of all, if you are using an outdated 10BASE-T Ethernet adapter to connect to the cable modem, you are limited to 10Mbps. A USB 1.1 port is limited to 12Mbps, but even this is well beyond the real-life results you will achieve. As with any LAN, you are sharing the available bandwidth with other users in your neighborhood. All your neighbors who also subscribe to the service use the same 6MHz channel. As more users are added, more systems are contending for the same bandwidth, and throughput goes down.

In November 1999, ZDTV (now TechTV) tested five brands of cable modems in typical operations and found that the overhead of CATV proved to be a major slowdown factor. The cable modems were first connected directly to the server to provide a baseline for comparisons. Some of these tests showed speeds as high as 4Mbps. However, when the CATV cable was connected and the same tests were run, the best performer dropped to just 1.1Mbps, with others running even slower. Of course, the picture has changed a bit since 1999. More recently, cable providers have been increasing speeds, with most offering 4Mbps8Mbps as part of their standard cable Internet service.

Tip

You can improve the performance of your cable modem or other broadband Internet access device by making changes to your system Registry that affect the size of the TCP receive window and other settings. I recommend the system tweaks available at the SpeedGuide.net website (www.speedguide.net). You can find tweaks for all Windows versions from Windows 95 through Windows XP, along with instructions on how to make the changes manually and easy methods for setting your system's Registry back to its default values.

CATV Performance

The fact that you are sharing the CATV network with other users doesn't mean the performance of a cable modem isn't usually spectacular. Although the CATV network takes a big cut out of the maximum speeds, you'll still realize a throughput that hovers between 512Kbps and 6Mbps, almost 10120 times that of the fastest modem connection and up to 48 times that of ISDN. You will find the Web to be an entirely new experience at this speed. Those huge audio and video clips you avoided in the past now download in seconds, and you will soon fill your hard drives with all the free software available.

Add to this the fact that the service is typically quite reasonably priced. Remember that the CATV provider is replacing both the telephone company (if you have two-way service) and your ISP in your Internet access solution. The price can be about \$40\$50 per month (including cable modem rental), which is twice that of a normal dialup ISP account, but it is far less than ISDN, does not require a telephone line (if your provider has two-way service), and provides 24-hour access to the Internet. The only drawback is that the service might not be available yet in your area. In my opinion, this technology exceeds all the other Internet access solutions available today in speed, economy, convenience, and widespread availability. Its nearest rival is DSL, which is still not as widely available geographically and is plagued with poor coordination between ISPs and telephone companies. Because cable modem Internet service providers provide the physical plant, provide ISP services, and can provide equipment, you can get service installed in just days and avoid the finger-pointing common with other types of broadband Internet service.

CATV Internet Connection Security

Because your PC is sharing a network with other users in your neighborhood and because the traffic is bidirectional on systems using two-way cable modems, the security of your PC and the network becomes an issue. In most cases, some form of encryption is involved to prevent unauthorized access to the network. CableLabs Certified (DOCSIS) cable modems have built-in encryption, but older one-way modems might not have this feature.

If you use an operating system such as 32-bit Windows that has built-in peer networking capabilities and your provider doesn't use CableLabs Certified cable modems or some other form of encryption, you might be able to see your neighbors' computers on the network. The operating system has settings that enable you to specify whether other network users can access your drives. If these settings are configured improperly, your neighbors might be able to view, access, and even delete the files on your hard drives. Be sure the technician from the cable company installing the service addresses this problem if your cable modem hardware doesn't provide encryption although this is rare today. If you want to use a cable modem along with sharing access on your computer (for printing, file storage, and so on), I'd recommend that you use passwords for any shared drives, but you're even safer if you disable file and printer sharing on the system you connect to the cable modem.

For more information on securing any type of Internet access, see "[Securing Your Internet Connection](#)," p. [1075](#).

Digital Subscriber Line

The biggest rival to the cable modem in the broadband Internet business is the digital subscriber line (DSL). DSL, like its predecessor ISDN, appeals to the telephone companies who might be able to use the existing POTS wiring to provide high-speed Internet access. Not every type of DSL is suitable for existing wiring; however, all but the fastest, most expensive types can sometimes be used with the existing POTS plant. DSL is also appealing to businesses that don't have access to cable modems but are looking for a high-performance, lower-cost alternative to the expensive ISDN services that top out at 128Kbps.

Note

Some technical discussions of DSL refer to xDSL. The x stands for the various versions of DSL being proposed and offered by local telephone companies and ISPs. DSL generally is used to refer to any type of digital subscriber line service.

One advantage of DSL compared to its most popular rival cable modems is that cable modems share common bandwidth, which means that a lot of simultaneous use by your neighbors can slow down your connection. If you use DSL you don't have this concern; whatever bandwidth speed you pay for is yours period.

How DSL Works

DSL takes advantage of the broadband nature of the telephone system, using the system's capability to carry signals at multiple frequencies to allow both high-speed Internet traffic and phone calls at the same time. Two methods for sending and receiving signals are used by the most common type of DSL, Asymmetric DSL (ADSL):

- Carrierless Amplitude/Phase (CAP)
- Discrete Multitone (DMT)

Most early DSL installations used CAP, which splits the telephone line into three frequency bands. Exact frequency usage varies by system, but most typically, the divisions resemble the following:

- Voice calls use frequencies from 30Hz to 4KHz. This frequency is also used by answering machines, fax machines, and alarm systems.
- Upstream data such as web page requests and sent email uses frequencies between 25Hz and 160Hz.
- Downstream data such as received web pages and email uses frequencies between 240KHz and 1.5MHz.

Some systems use the 300Hz-700Hz range for downstream data and frequencies of 1MHz and above for upstream data.

Because voice, downstream, and upstream data use different frequencies, you can talk, surf, and send email at the same time.

DMT, the system used by most recent ADSL installations, divides the telephone line into 247 channels that are 4KHz wide. If a particular channel has problems, a different channel with better signal quality is used automatically. Unlike CAP, DMT uses some channels starting at around 8KHz to send and receive information.

Both types of signaling can have problems with interference from telephones and similar devices, so devices called *low-pass filters* are used to prevent telephone signals from interfering with signals above the 4KHz range, where DSL signals begin. The location of these filters depends on the type of DSL you use and whether you are installing DSL service yourself.

At the central switch, DSL data is transferred to a device called a *DSL access multiplexer (DSLAM)*, which transfers outgoing signals to the Internet and sends incoming signals to the correct DSL *transceiver* (the correct name for the so-called "DSL modem" that connects to your computer).

Who Can Use DSL and Who Can't

DSL services have been slowly rolling out across the country for years, first to major cities and then to smaller cities and towns. As with 56Kbps modems, rural and small-town users are often the last to receive this service. If you live in an area without access to cable or Internet, you should consider satellite-based or fixed wireless Internet services where available for a faster-than-56Kbps experience.

Just as distance to a telephone company's central switch (CS) is an important consideration for people purchasing an ISDN connection, distance also affects who can use DSL in the markets offering it. For example, most DSL service types require that you be within about 18,000 feet (about 3 miles) wire distance to a telco offering DSL; some won't offer it if you're beyond 15,000 feet wire distance because the speed drops significantly at longer distances. Repeaters or a local loop that has been extended by the telco with fiber-optic line might provide longer distances. The speed of your DSL connection varies with distance: The closer you are to the telco, the faster your DSL access is. Many telcos that offer some type of DSL service provide websites that help you determine whether, and what type of, DSL is available to you.

If you want to locate DSL service providers in your area, compare rates, and see reviews from users of the hundreds of ISPs now providing DSL service, set your browser to <http://www.dslreports.com>. The site provides a verdict on many of the ISPs reviewed, summarizing users' experiences and ranking each ISP in five categories.

Note

If you want to connect DSL to your SOHO or office LAN, check first to see what the provider's attitude is. Some users report good cooperation, whereas others indicate they were told "we can't help you" or were told that DSL "couldn't be connected to a LAN." Fortunately, as home LANs continue to proliferate, this is becoming a less frequent problem. Again, check around for the best policies. Low-cost switch/router combinations from companies such as Linksys and D-Link and Microsoft's Internet Connection Sharing provide relatively easy ways to share both DSL and other types of high-speed connections.

Even if your telco's central switch is well within wire distance range of your location, that's no guarantee that you qualify for DSL service. The design and condition of the wiring plant connecting your location with the central switch can prevent you from qualifying for DSL service. Because DSL service depends on successful sending and receiving of high-frequency data, a telephone wiring plant that blocks high-frequency signals can't be used for DSL service. Some of the typical issues with telephone lines that aren't DSL-friendly include

- *Loading coils.* These amplifiers boost voice signals and are sometimes called voice coils. Unfortunately, these block the high-frequency signals needed by DSL service.
- *Bridge taps.* Used to extend service to new customers without running separate lines all the way back to the central switch. Bridge taps can create a circuit that's too long for DSL service.
- *Fiber-optic cables.* Used to carry a lot of signals in a small physical space, fiber-optic cables use analog-to-digital (A/D) and digital-to-analog (D/A) converters where they connect to copper telephone lines. A/D and D/A converters can't pass DSL signals through to their destinations.

Major Types of DSL

Although the term *DSL* is used in advertising and popular discussions to refer to any form of DSL, many, many variations of DSL are used in different markets and for different situations. This section discusses the most common forms of DSL and provides a table that compares the various types of DSL service. Although many types of DSL service exist, you can choose only from the service types offered by your DSL provider:

- *ADSL (Asymmetrical DSL).* The type of DSL used most often, especially in residential installations. Asymmetrical means that downstream (download) speeds are much faster than upstream (upload) speeds. For most users, this is no problem because downloads of web pages, graphics, and files are the major use of Internet connections. Maximum downstream speeds are up to 9Mbps, with up to 640Kbps upstream. Most vendors who offer ADSL provide varying levels of service at lower speeds and prices, as well. Voice calls are routed over the same wire using a small amount of bandwidth, making a single-line service that carries voice and data possible. ADSL is more expensive to set up than some other forms of DSL because a splitter must be installed at the customer site, meaning that you must pay for a service call (also called a truck roll) as part of the initial setup charge.
- *CDSL (Consumer DSL).* A slower (1Mbps downstream) form of DSL that was developed by modem chipset maker Rockwell. It doesn't require a service call because no splitter is required at the customer site.
- *G.Lite (Universal DSL, and also called DSL Lite or Splitterless DSL).* Another version that splits the line at the telco end rather than at the consumer end. Downstream speeds range from 1.544Mbps to 6.0Mbps, and upstream speeds can be from 128Kbps to 384Kbps. This is becoming one of the most popular forms of DSL because it enables consumers to use self-install kits. Note that the DSL vendor might cap the service at rates lower than those listed earlier in the chapter; check with the vendor for details.
- *SDSL (Symmetrical DSL).* This type of DSL service provides the same speed for upstream as for downstream service. Generally, SDSL is offered to business rather than residential customers because it requires new cabling (rather than reusing existing phone lines). A long-term contract frequently is required.

[Table 17.2](#) summarizes the various types of DSL.

Table 17.2. DSL Type Comparison

DSL Type	Description	Data Rate Downstream; Upstream	Distance Limit	Application
IDSL	ISDN Digital Subscriber Line	128Kbps	18,000 feet on 24-gauge wire	Similar to the ISDN BRI service but data only (no voice on the same line)
CDSL	Consumer DSL from Rockwell	1Mbps downstream; less upstream	18,000 feet on 24-gauge wire	Splitterless home and small business service; similar to DSL Lite
DSL Lite (same as G.Lite)	Splitterless DSL	From 1.544Mbps to 6Mbps downstream, depending on the subscribed service	18,000 feet on 24-gauge wire	Sacrifices speed for not having to install splitters
HDSL	High bit-rate Digital Subscriber Line	1.544Mbps duplex on two twisted-pair lines; 2.048Mbps duplex on three twisted-pair lines	12,000 feet on 24-gauge wire	T-1/E1 service between server and phone company or within a company
SDSL	Symmetric DSL	1.544Mbps duplex (U.S. and Canada); 2.048Mbps (Europe) on a single-duplex line downstream and upstream	12,000 feet on 24-gauge wire	Same as for HDSL but requiring only one line of twisted pair
ADSL	Asymmetric Digital Subscriber Line	1.544Mbps to 8.448Mbps downstream; 16Kbps to 640Kbps upstream	1.544Mbps at 18,000 feet; 2.048Mbps at 16,000 feet; 6.312Mbps at 12,000 feet; 8.448Mbps at 9,000 feet	The most common DSL used for Internet access
VDSL	Very High Subscriber Line Digital	12.9Mbps to 52.8Mbps downstream; 1.6Mbps to 2.3Mbps upstream	4,500 feet at 12.96Mbps; 3,000 feet at 25.82Mbps; 1,000 feet at 51.84Mbps	ATM networks; Fiber to the Neighborhood

With any type of DSL, an external device called a DSL *modem* is attached to the computer through either of the following:

- A crossover cable running to an Ethernet card or port in the computer
- A USB cable running to a USB port in the computer

An RJ-11 (standard telephone) cable is attached between the DSL modem and the RJ-11 port that has been

set up for DSL service.

To prevent telephone signals from interfering with DSL frequencies, splitters or microfilters must be installed on a DSL line. If you choose a technician-installed form of DSL, a device called a *splitter* is used at your location to prevent interference. Splitter-based DSL allows faster speeds than splitterless DSL installations, but the wait for a technician to show up and add the splitter can add days or weeks to your installation process.

If you self-install DSL, you will install small devices called *microfilters* to block interference from telephones, answering machines, and similar devices. These devices might fit behind the faceplate of the wall outlet used for DSL service or inline between the phone, answering machine, or fax machine and the wall outlet (see [Figure 17.2](#)).

Figure 17.2. Two types of DSL self-installations; if a splitter is used to set up a separate DSL line, the microfilters shown here are not necessary.

DSL Installation with In-line Microfilter

DSL Installation with Wall Outlet Microfilter

RJ-11 line cord

Tip

If you have a security system attached to your telephone line, watch out for problems if you select DSL as your preferred broadband access method. Security systems are often designed to seize the line, interrupting a phone call in progress to send an alarm to the security company. This feature won't work with normal microfilters, so you should purchase a special DSL Alarm filter to allow your alarm system to coexist with your DSL installation. Get more information about the alarm microfilter and alternative DSL installation options from www.hometech.com/learn/dsl.html.

DSL Pricing

DSL pricing varies widely, with different telephone companies offering different speeds of DSL and different rates. One thing that's true about the most commonly used flavors of DSL is that they are usually an asymmetrical service with download speeds faster than upload speeds. ADSL installations can typically be run over existing copper wires, whereas SDSL installations usually require that new high-quality copper wires be installed between the CO and the subscriber's location.

For unlimited use, typical residential DSL pricing ranges anywhere from \$15 to \$80 a month depending on whether you want a static or dynamic IP address and the download speed, which ranges from 256Kbps to 1.5Mbps. Business DSL pricing ranges from \$50 to as high as \$500 per month.

The wide variance is partly due to the upload speeds permitted. The lower-cost plans typically use a lower upload speed (some variation on ADSL or G.Lite); in contrast, the more expensive plans often use SDSL. Check carefully with your vendor because your traditional telephone company might not be the only DSL game in town. Some major cities might have as many as half a dozen vendors selling various flavors of DSL.

DSL Security Issues

Unlike other types of broadband access, DSL is a direct one-to-one connection that isn't shared; you have no digital "neighbors" who could casually snoop on your activities. However, as with any broadband "always-on" connection, intrusion from the Internet to your computer is a very real possibility and you should safeguard your system behind a router with firewall capabilities. Using an additional software firewall, such as the one included with Windows XP, is also a good idea.

►► For more information on securing any type of Internet access, see "[Securing Your Internet Connection](#)," p. [1075](#).

Technical Problems with DSL

Telecommunications has always had its share of difficulties, starting with the incredibly slow and trouble-plagued 300bps modems used on early PCs, but as speed increases, so do problems. DSL connections are often very difficult to get working correctly because DSL, as you've seen, combines the problems of adding high-speed data access to the telephone line with network configuration using TCP/IP (the most powerful and most complex network protocol in widespread use; see [Chapter 18](#), "Local Area Networking," for details).

A review of comments from DSL users in various forums, such as DSLReports.com and others, shows that the most common problems include the following:

- *Poor coordination between the DSL sales department of the telco or third-party provider and the installers.* This can lead to broken or very late appointments for installation; if possible, contact the installer company to verify the appointment. If possible, opt for a self-install version of DSL to avoid problems with late or missing appointments.
- *Installers who install the hardware and software and then leave without verifying it works properly.* Ask whether the installer carries a notebook computer that can test the line; don't let the installer leave until the line is working.
- *Poor technical support before and after installation.* Record the IP address and other information used during the installation; read reviews and tips from sources listed earlier in the chapter to help you find better DSL providers and solutions you can apply yourself or ask your telco or provider to perform.
- *Lower speeds than anticipated.* This can be due to a poor-quality connection to the telco from your home or business or problems at the central switch; ask the installer to test the line for you during initial installation and tell you the top DSL speed the line can reach. On a healthy line, the problem is often traceable to a very low value for the Windows Registry key called **RWIN** (receive window), which should be adjusted from its default of 8192 (8KB) to a value as high as 32768 (32KB) or even 65535 (64KB). If your system previously was used with a dialup modem, the value for **RWIN** can be as low as 2144; low values force your DSL connection to receive data at rates hardly faster than those for a dialup modem connection. For interactive tests that will help you find the best value to use for **RWIN** or other Registry options, find line problems, and adjust your configuration, go to <http://www.dslreports.com> and follow the Tools link from the home page.

Because of the problems with trying to retrofit an aging voice-oriented telephone network with high-speed Internet service, many pure DSL companies are having financial problems. Some once-prominent DSL ISPs went out of business in 2000/2001, leading to service cancellations in some cases. Before you sign a long-term contract for DSL service, you should determine what your options are if your telco, DSL line provider, or ISP drops DSL service.

Fixed-Base Wireless Broadband

If cable modem or DSL service isn't available at your location, you still might be able to get broadband Internet service through a fixed wireless broadband Internet provider. These services use various frequencies of microwave signals to connect to the Internet. Most of these are based on the same 2.4GHz frequencies 802.11 Wi-Fi connections use. These services typically require a small directional panel antenna to be mounted at the highest point on your roof and must have a clear line-of-sight view of the transmitter, which is usually mounted on a tower only a few miles away. Such services are therefore local, so you generally need to check your area to see whether they are available. Normally, I recommend fixed-base wireless only if cable modem or DSL service is unavailable, but I'd place it as a better overall choice than satellite service. In general, the initial equipment fees are less than satellite and the signals are more immune to weather problems.

To learn more about fixed-base wireless broadband, see the Technical Reference section on the disc packaged with this book.

Internet Connectivity via Satellite with DirecWAY or StarBand

If you're in an area where cable modem, DSL, or fixed wireless services don't exist, you might be able to use a satellite connection as a last resort. To see whether this is possible, take a look at the southern sky from your home, condo, or apartment building. If you have a good, clear 45° window view to the sky toward the equator and you want fast downloads of big files, a satellite-based service such as DirecWAY or StarBand might be the best (or only viable) high-speed choice for you.

Note

Geosynchronous satellites used for satellite Internet/TV service are visible in the southern sky for users in the Northern Hemisphere (North America, Europe, and Asia); if you're in the Southern Hemisphere (South America, Australia, Africa), these satellites are located in the northern sky.

Depending on the product you choose for satellite Internet, you might be able to use a single dish for both satellite Internet and satellite TV.

Tip

If you want both high-speed Internet access and satellite TV with a single dish, you can add DirecTV to the DirecWAY dish at any time. The StarBand dish can work with both Dish Network (TV) and StarBand (Internet) services in the continental United States and Canada. However, if you decide to add DirecWAY to an existing DirecTV setup, you will need to replace your existing DirecTV dish unless you installed the larger DirecDUO dish (which works with DirecTV and DirecPC or DirecWAY).

DirecWAY

DirecWAY was originally called DirecPC, but Hughes Network Systems renamed it in mid-2001, shortly after rolling out a two-way version of the DirecPC service; this section discusses the two-way service. The original version of DirecPC/DirecWAY was a one-way service that used satellite for downloading and a conventional dialup modem for uploads. Starting in 2002, this was replaced with a two-way satellite connection.

Currently, DirecWAY Home is advertised at 700Kbps for downloads, although most people experience much higher speeds of 1000Kbps2000Kbps. Uploads are more limited in speed to about 60Mbps. This might be slower than cable modems or DSL, but satellite connections are often the only available broadband connection for people living away from urban areas. If you're willing to spend a little more, DirecWAY also sells a Professional package that offers download speeds at 1Mbps.

DirecWAY Requirements

The DirecWAY service requires you to purchase and install a small satellite dish as part of the necessary hardware. It's similar to and slightly larger than the dishes used for satellite TV services, such as DirecTV and DishNetwork. In fact, you can combine DirecTV and DirecWAY service on the same dish in many cases, although generally you are better off keeping them separate. DirecWAY uses a 35" wide DirecWAY satellite dish to send and receive data. The dish is connected to a DW6000 satellite modem, which provides a shareable Ethernet connection to which you can plug an individual PC or a router to share the access on your network for Windows PC, Mac, and other systems. The DW6000 is functionally identical to a cable modem as far as setup and operation is concerned. This means that no custom software is required on the PC end. Older modems connected via USB and required a PC for connection, but those have since been phased out.

Purchasing DirecWAY Service

DirecWAY can be purchased from DirecWAY (www.direcway.com) as well as from partners such as EarthLink (www.earthlink.com).

You can either purchase the equipment up front (installation is included) and then pay a lower monthly fee or pay a higher monthly fee and avoid the greater upfront costs. Either way, you have to accept a minimum 15-month contract with penalties for early termination.

DirecWAY's FAPBrakes on High-speed Downloading?

A big concern for those wanting to exploit the high-speed download feature continues to be DirecWAY's Fair Access Policy (FAP). FAP uses unpublished algorithms to determine who is "abusing" the service with large downloads. This has proven to be a controversial feature. For example, the current guidelines for residential customers state that you might experience the FAP if the cumulative requested downloads in a 1-hour to 4-hour time period exceeds 169MB. The restrictions are lifted within 812 hours of the original application of the FAP if the usage in that period stays below the FAP threshold. The limits are higher for those using the Professional service and for business customers. For a more detailed discussion of the real-world impact of FAP on both residential and business users and software you can use to track downloading, see the Fair Access Policy page at <http://www.copperhead.cc/fap.html>.

Note

Because different satellites are used by the different DirecWAY partners, it pays to research which DirecWAY versions perform best. In addition to the DirecPC/DirecWAY newsgroup, check out the DirecPC Uncensored! website at www.copperhead.cc as well as the forums on www.dslreports.com for speed tests and tweaks you can make to your system.

StarBand

In April 2000, StarBandthe first consumer-oriented two-way satellite networkwas introduced after being tested as Gilat-At-Home. After some initial teething pains, StarBand has achieved success but is not as popular as DirecWAY. Even so, the feature set of StarBand in its current two-way form is almost identical to DirecWAY.

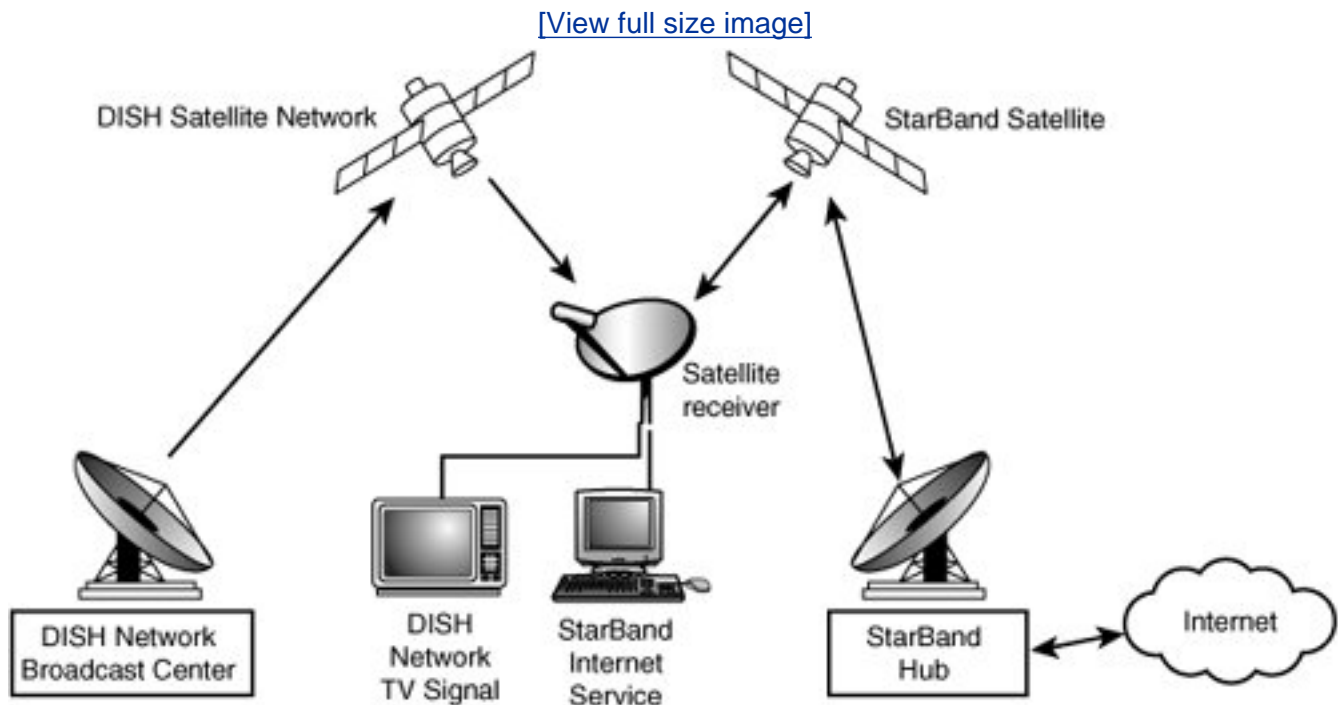

StarBand provides download speeds ranging from 500Kbps to 1000Kbps and upload speeds ranging from 50Kbps to 100Kbps, depending on the satellite modem used. StarBand has partnered with several other companies, including SIA (satellite-internet-access.net) and US Online (www.usonline.com), to support its products. StarBand equipment pricing and monthly service fees are generally similar to DirecWAY's two-way price structure, although some vendors might offer special promotional packages and bundles.

Tip

You can find excellent tips, tricks, utility software, and user-provided help at the StarBand Users website (www.starbandusers.com) as well as www.dslreports.com.

DirecWAY and StarBand services work as shown in [Figure 17.3](#).

Figure 17.3. The DirecWay and StarBand services can receive both TV programs (left) and Internet traffic (right) with a single 24"x36" satellite dish.

Real-world Satellite Performance

Benchmark addicts will find that satellite Internet access performs poorly on ping tests because the complex pathway your data must travel (ground to space and back again) results in pings taking at least 400ms600ms. Interactive benchmarks are also disappointing. The delays caused by communicating with a geosynchronous satellite over 22,500 miles in space make satellite a poor choice for these applications, although download speeds are significantly faster than dialup modems. Speeds vary widely, but speeds of 1000Kbps are common, and some can reach download speeds of more than 2000Kbps. To achieve results like this, use the tips available on the various forums and sites covering satellite connections to adjust your system's configuration.

Weather can be a problem for satellite connections, but not in the way you might think. Clouds and storms don't generally affect the signal, unless the storm is so severe you should probably be taking shelter anyway. What can be a problem, however, is snow and ice accumulation on the dish. If you live in an area where it snows, you can have signal problems even though the sky is clear; those problems are invariably caused by snow and ice accumulation on the dish. With that in mind, try to have the dish mounted in a location where you can periodically get to it to brush off any snow and ice accumulation.

Because of the higher latency, slower overall speeds, greater equipment costs, and sensitivity to snow and ice, few would recommend satellite service when alternatives are available. But when the only alternatives are dialup or having an expensive T1 line, satellite is certainly more attractive than the alternatives. Although the costs are higher than cable modem or DSL access, satellite might be the only even remotely cost-effective option for people outside urban areas. Many people have creatively adapted the dishes for use on a recreational vehicle (RV) when stationary or in various tripods and platforms for use while camping.

Integrated Services Digital Network

The connection speed of dialup modems is limited by Shannon's Law (see the section "56Kbps Modems," later in this chapter). To surpass the speed limitations of dialup modems, you need to use digital signals. Integrated Services Digital Network (ISDN) was the first step in the move to digital telecommunications. With ISDN, you can connect to the Internet at speeds of up to 128Kbps. Because ISDN was developed by the telephone companies, you can purchase a variety of service plans. Depending on the ISDN service you choose, you can use it strictly for Internet service or use it to service multiple telephony applications such as voice, fax, and teleconferencing.

Depending on where you live, you might find that ISDN service is available for Internet uses, or your local telco might offer faster DSL service as an alternative. Because ISDN was not originally designed for Internet use, its speed is much lower than other broadband options. Also, ISDN costs about twice what a typical ADSL or cable modem connection costs per month.

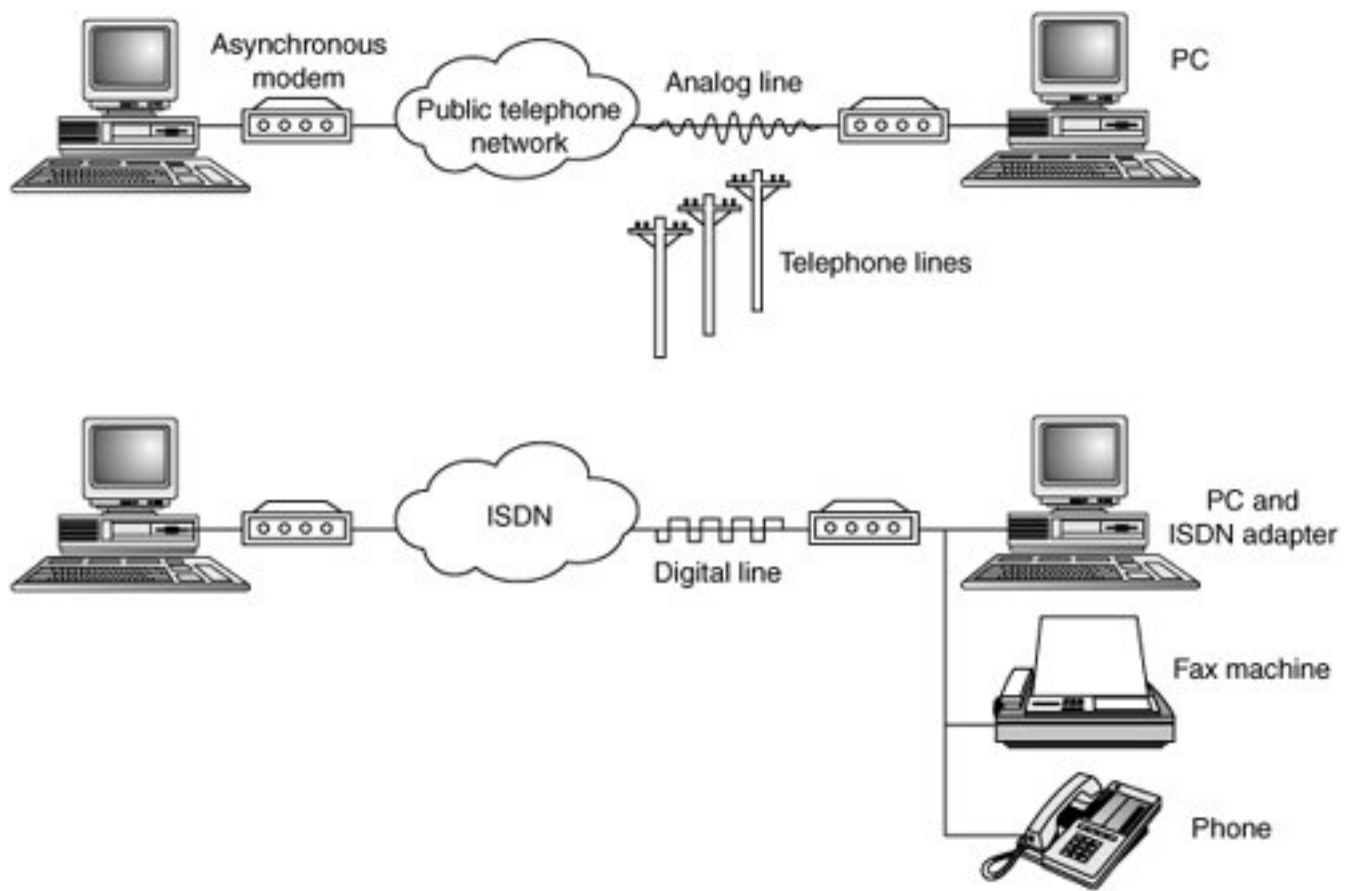

ISDN doesn't require as high a line quality as DSL, so it can be offered in areas where DSL can't work without a major upgrade of the telephone system.

How Standard ISDN Works

Because ISDN carries three channels, it allows integrated services that can include combinations such as voice+data, data+data, voice+fax, fax+data, and so on (see [Figure 17.4](#)).

Figure 17.4. A dialup modem connection (top) connects only your PC to the Internet or other online services, whereas ISDN (bottom) can connect your computer, fax, and many other devices via a single ISDN terminal adapter.

[\[View full size image\]](#)

On a standard ISDN connection, bandwidth is divided into bearer channels (B channels) that run at 64Kbps and a delta channel (D channel) that runs at either 16Kbps or 64Kbps, depending on the type of service. The B channels carry voice transmissions or user data, and the D channel carries control traffic. In other words, you talk, surf, or fax through the B-channel lines.

Two types of ISDN service exist: basic rate interface (BRI) and primary rate interface (PRI). The BRI service is intended for private and home users and consists of two B channels and one 16Kbps D channel, for a total of 144Kbps. The typical BRI service enables you to use one B channel to talk at 64Kbps and one B channel to run your computer for web surfing at 64Kbps. Hang up the phone, and both B channels become available. If your ISDN service is configured appropriately, your web browsing becomes supercharged because you're now running at 128Kbps.

The PRI service is oriented more toward business use, such as for PBX connections to the telephone company's central office. In North America and Japan, the PRI service consists of 23 B channels and 1 64Kbps D channel for a total of 1536Kbps, running over a standard T-1 interface. In Europe, the PRI service is 30 B channels and 1 64Kbps D channel, totaling 1984Kbps, which corresponds to the E1 telecommunications standard. For businesses that require more bandwidth than one PRI connection provides, 1 D channel can be used to support multiple PRI channels using non-facility associated signaling (NFAS).

The BRI limit of two B channels might seem limiting to anyone other than a small office or home office user, but this is misleading. The BRI line can actually accommodate up to eight ISDN devices, each with a unique ISDN number. The D channel provides call routing and "on-hold" services, also called *multiple call signaling*, allowing all the devices to share the two B channels.

Note

When speaking of ISDN connections, 1 kilobyte equals 1,000 bytes, not 1,024 bytes as in standard computer applications.

As you saw earlier, this is also true of speed calculations for modems. Calculations that use 1,000 as a base are often referred to as *decimal* kilobytes, whereas the ones based on 1,024 are now called *kibibytes* or *binary* kilobytes.

If you need a more powerful, more flexible (and more expensive) version of ISDN, use the PRI version along with a switching device, such as a PBX or server. Although PRI allows only one device per B channel, it can dynamically allocate unused channels to support high-bandwidth uses, such as video-conferencing, when a switching device is in use along with PRI.

Acquiring ISDN Service

To have an ISDN connection installed, you must be within 18,000 wire feet (about 3.4 miles or 5.5km) of the CO (telco central office or central switch) for the BRI service; *wire feet* refers to the distance traveled by the telephone wires serving your location, not straight-line distance. For greater distances, expensive repeater devices are needed, and some telephone companies might not offer the service at all.

Prices for ISDN service vary widely depending on your location. In the United States, the initial installation fee can range from \$35 to \$150, depending on whether you are converting an existing line or installing a new one. The monthly charges typically range from \$30 to \$50, and sometimes you must pay a connect-time charge as well, ranging from 1 to 6 cents per minute or more, depending on the state. Keep in mind that you also must purchase an ISDN terminal adapter for your PC and possibly other hardware as well, and these charges are only for the telephone company's ISDN service. In addition, you must pay your ISP for access to the Internet at ISDN speeds. Typically, when all charges are included, you can pay up to \$100 or more per month for ISDN service in a residential setting, and more for a small business connection. Residential plans are often dialup, requiring you to make a connection to the ISP's server every time you want to go online, whereas business plans are usually always-on, with immediate connection.

Note

Although ISDN Internet access provided by your local telephone company usually has a single price for the ISDN line and ISDN Internet access, most third-party ISDN ISPs provide pricing for only Internet access. These costs might appear to be much less expensive at startup and per month than what the telco's ISDN package costs, but this is misleading because the telco's charges for ISDN service aren't included. Add up the costs from both the ISP and the telephone company for a true picture of third-party ISDN Internet service pricing.

Because ISDN pricing plans offer many options depending on the channels you want and how you want to use them, be sure you carefully plan how you want to use ISDN. Check the telco's website for pricing and package information to get a jump on the decision-making process. Although ISDN is unique among broadband Internet services for its capability to handle both voice and data traffic, its relatively high cost and low speed make it a poor choice for most small-office and home-office users.

ISDN Hardware

To connect a PC to an ISDN connection, you must have a hardware component called a *terminal adapter (TA)*. The terminal adapter takes the form of an expansion board or an external device connected to a serial port, much like a modem. In fact, terminal adapters often are mistakenly referred to as ISDN modems. Actually, they are not modems at all because they do not perform analog/digital conversions.

Because an ISDN connection originally was designed to service telephony devices, most ISDN terminal adapters have connections for telephones, fax machines, and similar devices, as well as for your computer. Some terminal adapters can also be used as routers to enable multiple PCs to be networked to the ISDN connection.

Caution

To achieve the best possible performance, you should either purchase an external ISDN terminal adapter that connects to your computer's USB port or use an internal version. A terminal adapter with compression enabled easily can exceed a serial port's capability to reliably send and receive data. Consider that even a moderate 2:1 compression ratio exceeds the maximum rated speed of 232Kbps, which most high-speed COM ports support. USB 1.1 ports, on the other hand, can handle signals up to 12Mbps, easily supporting even the fastest ISDN connection. USB 2.0 ports available on the latest computers support speeds up to 480Mbps.

Note

For more information about ISDN hardware and configuration, see *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the disc packaged with this book.

Comparing High-speed Internet Access

One way of making sense out of the confusing morass of plans available from cable modem, DSL, fixed wireless Internet, and satellite vendors is to calculate the average cost per Kbps of data downloaded (\$/Kbps). You can calculate this figure yourself by dividing the service cost (\$SC) per month by the rated or average speed of the service (\$SPD):

$$\$SC / \$SPD = \$/\text{Kbps}$$

For example, a typical cable modem service costs \$50 per month, including cable modem lease, and has an average (not peak) speed of 1000Kbps. Divide \$50 by 1000Kbps, and the cost per Kbps equals 5 cents.

Use this formula with any broadband or dialup service to find the best values. Don't forget to calculate the cost of required equipment (as in the example). If you must pay for equipment or installation upfrontas you will need to do with satellite, fixed wireless, and ISDN Internet plansdivide the upfront cost by the number of months you plan to keep the service and add the result to the monthly service charge to get an accurate figure.

How does a typical 56Kbps modem compare, assuming 50Kbps download speeds? Using Juno Web (\$14.95 per month) and assuming no charge for a dialup modem, the cost per Kbps is 29.9 cents per Kbpsalmost three times as much for service that is at least 10 times slower than a typical cable modem.

Generally, the services stack up as shown in [Table 17.3](#), from slowest to fastest when download speeds are compared.

Table 17.3. Comparing Typical Speeds for Various Types of Internet Connections

Connection Type	Speed (Kbps)	Connection Type	Speed (Kbps)
V.34 dialup	33.6/33.6	Basic DSL	384/128
V.90/92 dialup	53/33.6	Satellite (two-way)	500/60
ISDN (1BRI)	64/64	Premium DSL	3000/128
ISDN (2BRI)	128/128	Premium wireless	3000/256
Basic wireless	256/256	Cable modem	8000/384

The values in this table indicate various vendor maximum ratings; maximum values available in your area will depend on specific vendors and offerings. These figures do not indicate actual average speeds and do not take into account turn-around (ping) speeds or other issues such as network traffic.

Another way to compare Internet connection types is by feature, as in [Table 17.4](#).

Table 17.4. Comparing High-speed Internet Access by Feature

Service	Always On?	Reliability Affected By?	Connection to Network
Cable modem	Yes	Cable outages	Ethernet
DSL	Yes	Phone line outages	Ethernet
Fixed wireless	Yes	Transmitter outages; obstructions	Ethernet
Satellite (two-way)	Yes	Weather; satellite outages	Ethernet

Having a Backup Plan in Case of Service Interruptions

Because no high-speed connection is immune to service interruptions, you should consider having some type of backup plan in place in case of a significant service outage.

If your high-speed Internet access uses an ISP that can also accept dialup connections, you can use your regular modem for emergencies. However, this might require an extra charge in some cases. You could also consider using a free trial subscription to an ISP that uses a conventional modem. If you temporarily switch to a different ISP, especially one that uses its own client, such as AOL, be sure to back up your current Internet configuration information before you install the client software. Your best bet is to use an Internet-only ISP whose dialup connection can be configured manually with the Dialup Networking Connection Wizard or Network Setup Wizard in XP. Then, you can construct a new connection without destroying your existing configuration.

If you don't want to spend \$15-\$25/month for an additional dialup service, or if you travel occasionally and want a low-cost way to work online when you're away from broadband, consider using a broadband vendor who also offers dialup connections such as EarthLink (www.earthlink.com) or SpeakEasy (www.speakeasy.net). Having both broadband and dialup access is essential for those who travel because broadband connections are not always available when on the road. Also, if your broadband connection goes down for some reason, you can usually check the broadband carrier or network status online using a dialup connection to access the company's web pages.

Note

Each type of Internet connection uses a particular combination of TCP/IP settings. TCP/IP is the protocol (software rules) used by all computers on the Internet. TCP/IP is covered in [Chapter 18](#), but for now keep in mind that different TCP/IP settings are required for modem access and access through a NIC or USB port device (cable modem, DSL, and DirecWAY or StarBand). Modems usually have an IP address provided dynamically by the ISP when the modem connects with the ISP. The other types of Internet access devices might have static IP addresses that don't change or have dynamically assigned IP addresses. IP addresses are just one of the network settings that, if changed, prevent you from connecting to the Internet.

Leased Lines

For users with high bandwidth requirements (and deep pockets), dedicated leased lines provide digital service between two locations at speeds that can far exceed ISDN and are as fast or faster than DSL or cable modem. A *leased line* is a permanent 24-hour connection to a particular location that can be changed only by the telephone company. Businesses use leased lines to connect LANs in remote locations or to connect to the Internet through a service provider. Leased lines are available at various speeds, as described in the following sections.

T-1 and T-3 Connections

To connect networks in distant locations, networks that must support a large number of Internet users, or especially organizations that will be hosting their own Internet services, a T-1 connection might be a wise investment. A *T-1* is a digital connection running at about 1.5Mbps. This is more than 10 times faster than an ISDN link and is more than double the speed of most fast DSL connections. A T-1 can be split (or fractioned), depending on how it is to be used. It can be split into 24 individual 64Kbps lines or left as a single high-capacity pipeline. Some ISPs allow you to lease any portion of a T-1 connection that you want (in 64Kbps increments). SBC (formerly Ameritech), for example, offers a flexible T-1 service it calls DS1; it's available at full bandwidth or in various fractional sizes. [Figure 17.5](#) shows how a T-1 line is fractioned.

Figure 17.5. Full T-1 service uses all 24 lines (each one is 64Kbps) as a single pipeline; a fractional T-1 service of 256Kbps could use slots 14 only, for example.

An individual user of the Internet interacts with a T-1 line only indirectly. No matter how you're accessing the Internet (dialup modem, ISDN, DSL, cable modem, DirecWAY, StarBand, or fixed-base wireless), your ISP typically will have a connection to one or more T-1 or T-3 lines, which connect to the backbone of the Internet. This connection to the backbone is sometimes referred to as a *point of presence (PoP)*. When you make your connection to the Internet, your ISP shares a small chunk of that T-1 pipe with you. Depending on how many other users are accessing the Internet at your ISP or elsewhere, you might experience very fast to slow throughput, even if your modem connection speed remains constant. It's a bit like splitting up a pizza into smaller and smaller slices to accommodate more people at a party: The more users of a high-speed connection, the slower each individual part of it will be. To keep user connections fast while growing, ISPs add full or fractional T-1 lines to their points of presence. Or, they might switch from a T-1 connection to the even faster T-3 if available.

Note

Equivalent in throughput to approximately 28 T-1 lines, a T-3 connection runs at 45Mbps and is suitable for use by very large networks and university campuses. Pricing information falls into the "if-you-have-to-ask-you-can't-afford-it" category.

If your Internet connection is on a corporate LAN or your office is located in a downtown building, your relationship to a T-1 line might be much closer. If your building or office is connected directly to a T-1, you're sharing the capacity of that line with just a relatively few other users rather than with the hundreds or thousands of dialup users a normal ISP is hosting at one time. Full or fractional T-1 lines are being added to more and more apartments and office buildings in major cities to allow residents and workers faster Internet access. In these cases, a LAN connection to the T-1 is usually provided, so your Internet access device is a network card, rather than a modem or ISDN terminal adapter.

With the rise of the Internet and the demand for high-speed data access for networks, the price of T-1 links in the United States has fallen drastically since the late 1990s, although you will still pay in the hundreds of dollars for typical service offerings. T-1 service can be acquired from either your local telco or third-party firms. Fractional T-1 or burstable T-1 (which allows you to have differing levels of bandwidth up to the entire T-1 1.5Mbps depending on demand) costs less than full T-1 service. For a large organization that requires a lot of bandwidth, the lower cost of T-1 services today make installing a higher-capacity service and growing into it rather than constantly upgrading the link more economical than ever. Although the speed of T-1 links resembles the maximum rates available with DSL or cable modem service, most types of T-1 service provide constant bandwidth (unlike cable modems) and bypass the potentially severe problems of trying to retrofit old phone lines with digital service (unlike DSL).

Comparing Conventional High-speed Services

Some telcos who formerly posted pricing for ISDN, T-1, or other high-end telecommunications services now have a "call us" button on their websites because pricing is complicated by many factors, including

- Location (state and locality because telephone companies are regulated public utilities)
- Fixed and variable costs
- Usage
- Installation costs
- Your needs

Be sure to consider hardware and usage costs when you price services, and (for items such as ISDN terminal adapters and network cards) compare the official offerings with products available elsewhere. If you decide to provide some of the equipment yourself, find out whose responsibility repairs become. Some companies provide lower-cost "value" pricing for services in which you agree to configure the hardware yourself and maintain it. If you have knowledgeable staffers who can handle routers and other network configuration, you can save money every month, but if not, go with the full-service option.

Securing Your Internet Connection

Because any Internet connection must use TCP/IP, which uses built-in logical ports numbered 065,535 to service different types of activity, any user of the Internet can be vulnerable to various types of Internet attacks, even if precautions such as turning off drive and folder sharing have been followed. Such vulnerabilities increase drastically with always-on broadband services such as DSL and cable modems.

Steve Gibson of Gibson Research Corporation (makers of the classic SpinRite disk maintenance program) has established a free web-based service called Shields Up that you should try with *any* Internet-connected PC to see how safe or vulnerable you are.

The Shields Up portion of the Gibson Research Corporation website (<http://www.grc.com>) probes your system's Internet connection security and Internet service ports.

After testing your system, Shields Up provides reviews and recommendations for proxy server and firewall software (such as ZoneAlarm, Norton Internet Security, and Sygate Personal Firewall) that you can use to help secure your system.

With the increasing importance of the Internet and the multiple vulnerabilities we've seen since 2000 to Internet-borne viruses, Trojan horses, and denial-of-service attacks, Shields Up provides a valuable service for *any* Internet user.

[Chapter 18](#) discusses how using a router to share your Internet connection can also help protect your system against intruders.

Note

Proxy servers and firewalls are subjects that go far beyond the scope of this book. If you want to learn more, I suggest you pick up a copy of *Upgrading and Repairing Networks* also published by Que.

Que's *Absolute Beginner's Guide to Security, Spam, and Spyware* by Andy Walker is another excellent resource for users who want to install a personal firewall or otherwise protect their systems from the darker denizens of the Internet.

Asynchronous (Dialup) Modems

If you want to connect to the Internet without spending a lot of money, a dialup modem can serve as your on-ramp to the rest of the computing world. Modems are standard equipment with most recent systems and continue to be popular upgrades for systems that do not have access to broadband solutions, such as two-way cable modem or DSL lines. Even with some types of broadband access (such as one-way DirecWAY and one-way cable modem), modems are still needed to send page requests and email.

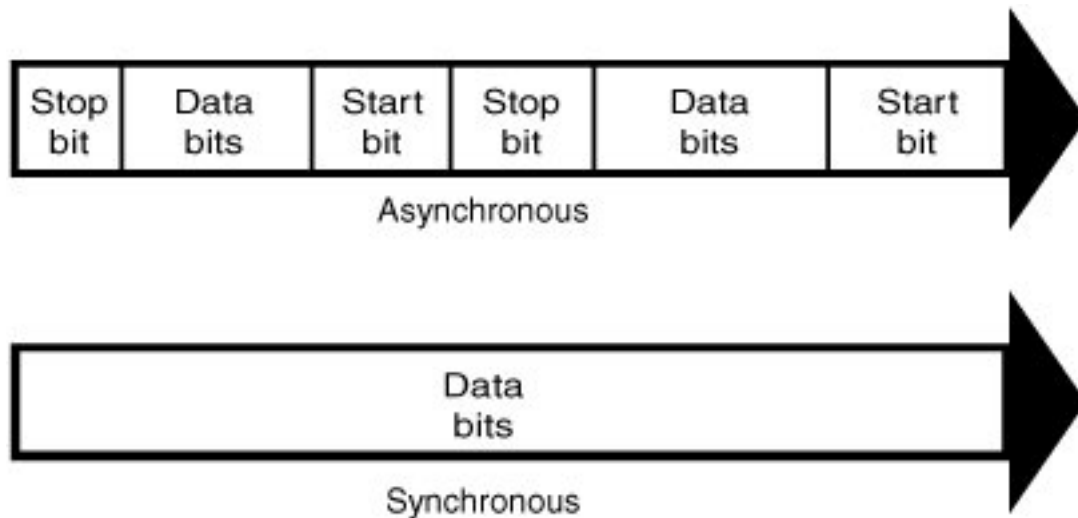

The word *modem* (from modulator/demodulator) basically describes a device that converts the digital data used by computers into analog signals suitable for transmission over a telephone line and converts the analog signals back to digital data at the destination. To distinguish modems that convert analog and digital signals from other types of access devices, modems are frequently referred to as *analog modems*; because you must dial a telephone number to reach a remote computer, they are also referred to as *dialup modems*. The typical PC modem is an asynchronous device, meaning it transmits data in an intermittent stream of small packets. The receiving system takes the data in the packets and reassembles it into a form the computer can use.

Note

Because it has become such a familiar term, even to inexperienced computer users, the word *modem* is sometimes used to describe devices that are, strictly speaking, not modems at all. For example, earlier in this chapter you read about broadband solutions such as ISDN, cable modems, DirecWAY, DSL, and StarBand. Although all these services use devices commonly called "modems" to connect your PC to fast online services, not all of them convert digital information to analog signals. However, because these devices look similar to a standard modem and are used to connect PCs to the Internet or to other networks, they are called modems.

Asynchronous modems transmit each byte of data individually as a separate packet. One byte equals 8 bits, which, using the standard ASCII codes, is enough data to transmit a single alphanumeric character. For a modem to transmit asynchronously, it must identify the beginning and end of each byte to the receiving modem. It does this by adding a start bit before and a stop bit after every byte of data, thus using 10 bits to transmit each byte (see [Figure 17.6](#)). For this reason, asynchronous communications have sometimes been referred to as *start-stop* communications. This is in contrast to synchronous communications, in which a continuous stream of data is transmitted at a steady rate.

Figure 17.6. Asynchronous modems frame each byte of data with a start bit and a stop bit, whereas synchronous communications use an uninterrupted stream of data.

Synchronous modems generally are used in leased-line environments and in conjunction with multi-plexers to communicate between terminals to Unix- or Linux-based servers and mainframe computers. Thus, this type of modem is outside the scope of this book.

Whenever modems are referred to in this book, I will be discussing the asynchronous, analog variety. (Synchronous modems are not found in typical computer stores and aren't included in normal computer configurations, so you might not ever see one unless you go into the data center of a corporation that uses them.)

Note

During high-speed modem communications, the start and stop bits are usually not transmitted over the telephone line. Instead, the modem's data compression algorithm eliminates them. However, these bits are part of the data packets generated by the communications software in the computer, and they exist until they reach the modem hardware. If both ends of a dialup modem connection don't use the same value for start and stop bits, the connection transmits gibberish instead of usable data.

The use of a single start bit is required in all forms of asynchronous communication, but some protocols use more than one stop bit. To accommodate systems with different protocols, communications software products usually enable you to modify the format of the frame used to transmit each byte. The standard format used to describe an asynchronous communications format is parity/data bits/stop bits. Almost all asynchronous connections today are therefore abbreviated as N-8-1 (No parity/8 data bits/1 stop bit). The meanings for each of these parameters and their possible variations are as follows:

- *Parity.* Before error-correction protocols became standard modem features, a simple parity mechanism was used to provide basic error checking at the software level. Today, this is almost never used, and the value for this parameter is nearly always set to none. Other possible parity values you might see in a communications software package are odd, even, mark, and space.
- *Data Bits.* This parameter indicates how many bits are actually carried in the data portion of the packet (exclusive of the start and stop bits). PCs typically use 8 data bits, but some types of computers use a 7-bit byte, and others might call for other data lengths. Communications programs provide this option to prevent a system from confusing a stop bit with a data bit.
- *Stop Bits.* This parameter specifies how many stop bits are appended to each byte. PCs typically use

1 stop bit, but other types of protocols might call for the use of 1.5 or 2 stop bits.

In most situations, you will never have to modify these parameters manually, but the controls are almost always provided. In Windows 9x/Me/2000/XP, for example, if you open the Modems control panel and look at the Connection page of your modem's Properties dialog box, you will see Data Bits, Parity, and Stop Bits selectors.

Unless you use the Windows HyperTerminal program to establish a direct connection to another computer via phone lines, you might never need to modify these parameters. However, if you need to call a mainframe computer to perform terminal emulation for e-banking, checking a library's catalog, or working from home, you might need to adjust these parameters. (*Terminal emulation* means using software to make your PC keyboard and screen act like a terminal, such as a DEC VT-100 and so on.) Many mainframe computers use even parity and a 7-bit word length. If your PC is set incorrectly, you'll see garbage text on your monitor instead of the other system's login or welcome screen.

Modem Standards

For two modems to communicate, they must share the same *protocol*. A protocol is a specification that determines how two entities will communicate. Just as humans must share a common language and vocabulary to speak with each other, two computers or two modems must share a common protocol. In the case of modems, the protocol determines the nature of the analog signal the device creates from the computer's digital data.

Bell Labs (which set standards for early 300bps modems) and the CCITT are two of the bodies that have set standards for modem protocols. CCITT is an acronym for Comité Consultatif International Téléphonique et Télégraphique, a French term that translates into English as the Consultative Committee on International Telephone and Telegraph. The organization was renamed the International Telecommunication Union (ITU) in the early 1990s, but the protocols developed under the old name are often referred to as such. Newly developed protocols are called ITU-T standards, which refers to the Telecommunication Standardization Sector of the ITU. Most modems built in recent years conform to the standards developed by the CCITT/ITU.

The ITU, headquartered in Geneva, Switzerland, is an international body of technical experts responsible for developing data communications standards for the world. The group falls under the organizational umbrella of the United Nations, and its members include representatives from major modem manufacturers, common carriers (such as AT&T), and governmental bodies. The ITU establishes communications standards and protocols in many areas, so one modem often adheres to many different standards, depending on its various features and capabilities.

All modems sold today support the following ITU protocols:

- ITU V.90 (modulation)
- ITU V.42 (error correction)
- ITU V.42bis (data compression)

However, earlier modems supported many industry-standard and proprietary protocols for modulation, error correction, and data compression.

Most modems today also support the proprietary Microcom Network Protocol (MNP) MNP10 and MNP10EC error-correction standards to provide better connection during conventional wired and wireless (cellular) communication sessions. The latest modems also support the newest ITU standards: V.92 (modulation) and V.44 (data compression). All current protocols are discussed later in this chapter.

Note

To learn more about earlier industry-standard and proprietary protocols, see [Chapter 18](#) of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the disc packaged with this book.

Note

The term *protocol* is also used to describe software standards that must be established between different computers to allow them to communicate, such as TCP/IP.

Modems are controlled through AT commands, which are text strings sent to the modem by software to activate the modem's features. For example, the **ATDT** command followed by a telephone number causes the modem to dial that number using tone dialing mode. Applications that use modems typically generate AT commands for you, but you can control a modem directly using a communications program with a terminal mode or even the **DOS ECHO** command.

Because almost every modem uses the AT command set (originally developed by modem-maker Hayes), this compatibility is a given and should not really affect your purchasing decisions about modems. The basic modem commands might vary slightly from manufacturer to manufacturer, depending on a modem's special features, but the basic AT command set is all but universal.

Note

A list of the basic AT commands can be found in the Technical Reference on the disc included with this book. However, the best source for the commands used by your modem is the manual that came with the device.

Although most modem users will never need to review these commands, if you use MS-DOSbased communication programs or some specialized Windows programs, you might be required to enter or edit an *initialization string*, which is a series of AT commands sent to the modem before dialing. If these commands are not correct, the modem will not work with these programs.

Bits and Baud Rates

When discussing modem transmission speeds, the terms *baud rate* and *bit rate* are often confused. Baud rate (named after a Frenchman named Emile Baudot, the inventor of the asynchronous telegraph printer) is the rate at which a signal between two devices changes in 1 second. If a signal between two modems can change frequency or phase at a rate of 300 times per second, for example, that device is said to communicate at 300 baud.

Thus, baud is a signaling rate, not a data-transmission rate. The number of bits transmitted by each baud is used to determine the actual data-transmission rate (properly expressed as bps or Kbps). Modern dialup modems transmit and receive more bits per baud than the original 300bps modems (which also ran at 300 baud).

Note

To learn more about bits versus baud, see [Chapter 18](#) of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the disc packaged with this book.

Modulation Standards

Modems start with modulation, which is the electronic signaling method used by the modem. Modulation is a variance in some aspect of the transmitted signal. By modulating the signal using a predetermined pattern, the modem encodes the computer data and sends it to another modem that demodulates (or decodes) the signal. Modems must use the same modulation method to understand each other. Each data rate uses a different modulation method, and sometimes more than one method exists for a particular rate.

Regardless of the modulation method, all modems must perform the same task: Change the digital data used inside the computer (ON-OFF, 1-0) into the analog (variable tone and volume) data used by the telephone company's circuits, which were built over a period of years and were never intended for computer use. That's the "mo(dulate)" in modem. When the analog signal is received by the other computer, the signal is changed back from the analog waveform into digital data (see [Figure 17.7](#)). That's the "dem(odulate)" in modem.

Figure 17.7. The modem at each computer changes digital (computer) signals to analog (telephone) signals when transmitting data or analog back to digital when receiving data.

[\[View full size image\]](#)

The three most popular modulation methods are as follows:

- *Frequency-shift keying (FSK)*. A form of frequency modulation, otherwise known as FM. By causing and monitoring frequency changes in a signal sent over the phone line, two modems can send information.
- *Phase-shift keying (PSK)*. A form of phase modulation in which the timing of the carrier signal wave is altered and the frequency stays the same.
- *Quadrature amplitude modulation (QAM)*. A modulation technique that combines phase changes with signal-amplitude variations, resulting in a signal that can carry more information than the other methods.

All modem protocols since ITU V.34 (33.6Kbps maximum speed) up through the current ITU V.90 and ITU V.92 standards (56Kbps maximum speed) are full-duplex protocols. A *full-duplex* protocol is one in which communications can travel in both directions at the same time and at the same speed. A telephone call, for example, is full duplex because both parties can speak at the same time. In *half-duplex* mode, communications can travel in both directions, but only one side can transmit at a time. A radio call in which only one party can speak at a time is an example of half-duplex communications.

These protocols are automatically negotiated between your modem and the modem at the other end of the connection. Basically, the modems start with the fastest protocol common to both and work their way down to a speed/protocol combination that will work under the line conditions existing at the time of the call.

The ITU V.90 and V.92 protocols are the industry-standard protocols most commonly used today; V.92 modems also support V.90.

Note

The 56Kbps standards that represent the highest current increment in modem communication speed require a digital connection at one end and are therefore not purely analog. Other high-speed communication technologies such as ISDN and cable network connections don't perform digital-to-analog conversions, so they should not be called modems, strictly speaking.

V.90

V.90 is the ITU-T designation for a 56Kbps communication standard that reconciles the conflict between the proprietary U.S. Robotics (3Com) x2 and Rockwell K56flex modem specifications developed in 1996 and 1997. The last ISA modems manufactured by major vendors typically support V.90, as do many PC Card and PCI modems built from 1998 to 2001.

▶▶ See "[56Kbps Modems](#)," p. [1082](#).

V.92

V.92 is the ITU-T designation for an improved version of the V.90 standard that provides faster negotiation of the connection, call-waiting support, and faster uploading than is possible with V.90. Most PCI and PC Card modems sold by major vendors since mid-2001 to the present are V.92 compatible.

▶▶ See "[56Kbps Modems](#)," p. [1082](#).

V.90 and V.92 are the current communication protocols supported by ISPs; any modem you want to use today should support at least the V.90 protocol.

Error-Correction Protocols

Error correction refers to the capability of some modems to identify errors during a transmission and to automatically resend data that appears to have been damaged in transit. Although you can implement error correction using software, this places an additional burden on the computer's expansion bus and processor. By performing error correction using dedicated hardware in the modem, errors are detected and corrected before any data is passed to the computer's CPU.

As with modulation, both modems must adhere to the same standard for error correction to work. Fortunately, most modem manufacturers use the same error-correction protocols.

V.42, MNP10, and MNP10EC Error-Correction Protocols

The current error-correction protocols supported by modems include Microcom's proprietary MNP10 (developed to provide a better way to cope with changing line conditions) and MNP10EC (an enhanced version developed to enable modems to use constantly changing cellular telephone connections).

V.90 and V.92 modems (as well as some older models) also support the ITU V.42 error-correction protocol, with fallback to the MNP 4 protocol (which also includes data-compression). Because the V.42 standard includes MNP compatibility through Class 4, all MNP 4-compatible modems can establish error-controlled connections with V.42 modems.

This standard uses a protocol called Link Access Procedure for Modems (LAPM). LAPM, similar to MNP, copes with phone-line impairments by automatically retransmitting data corrupted during transmission, ensuring that only error-free data passes between the modems. V.42 is considered to be better than MNP 4 because it offers approximately a 20% higher transfer rate due to its more intelligent algorithms.

Note

For information about the MNP 14 protocols, see [Chapter 18](#) of *Upgrading and Repairing PCs, 11th Edition*, included in electronic form on the disc packaged with this book.

Data-Compression Standards

Data compression refers to a built-in capability in some modems to compress the data they're sending, thus saving time and money for modem users. Depending on the type of files the modem is sending, data can be compressed to nearly one-fourth its original size, effectively quadrupling the speed of the modem at least in theory. This assumes that the modem has V.42bis data compression built in (true since about 1990) *and* that the data hasn't already been compressed by software. Thus, in reality, the higher throughput caused by data compression applies only to HTML and plain-text files on the Web. Graphics and Zip or EXE archives have already been compressed, as have most PDF (Adobe Acrobat Reader) files. Another factor that influences the throughput of a modem is the type of UART chip used by the serial port included in an internal modem or connected to an external modem, or the use of a USB port instead of a serial port.

Note

To learn more, see "Can Non-56Kbps Modems Achieve Throughput Speeds Above 115,200bps?" in the Technical Reference section of the disc packaged with this book.

As with error correction, data compression can also be performed with software. Data can be compressed only once, so if you are transmitting files that are already in a compressed form, such as Zip archives, GIF or JPEG images, or Adobe Acrobat PDF files, there will be no palpable increase in speed from the modem's hardware compression. The transmission of plain-text files (such as HTML pages) and uncompressed bitmaps, however, is accelerated greatly by modem compression.

MNP5 and V.42bis

Current data-compression standards in modems include Microcom's MNP 5 and the ITU V.42bis protocols. V.42bis is a CCITT data-compression standard similar to MNP Class 5, but it provides about 35% better compression. V.42bis is not actually compatible with MNP Class 5, but nearly all V.42bis modems include the MNP 5 data-compression capability as well.

V.42bis is superior to MNP 5 because it analyzes the data first and then determines whether compression would be useful. V.42bis compresses only data that needs compression. MNP 5, on the other hand, always attempts to compress the data, which slows down throughput on previously compressed files.

To negotiate a standard connection using V.42bis, V.42 also must be present. Therefore, a modem with V.42bis data compression is assumed to include V.42 error correction. When combined, these two protocols result in an error-free connection that has the maximum data compression possible.

V.44

At the same time that the V.92 protocol was introduced by the ITU in mid-2000, a companion data-compression protocol called V.44 was also introduced by the ITU. V.44 uses a new lossless LZJH compression protocol designed by Hughes Network Systems (developers of the DirecWAY satellite broadband Internet service) to achieve performance more than 25% better than that of V.42. Data throughput with V.44 can reach rates of as much as 300Kbps, compared to 150Kbps200Kbps with V.42bis. V.42bis was developed in the late 1980s, long before the advent of the World Wide Web, so it is not optimized for web surfing the way V.44 is. V.44 is especially designed to optimize compression of HTML text pages.

Note

V.44 is the latest compression algorithm to be based in part on the work of mathematicians Abraham Lempel and Jakob Ziv in the late 1970s. Lempel and Ziv's work also has been used in the development of LZW (Lempel-Ziv-Welch) compression for TIFF image files, GIF compressed image files, PKZIP-compatible compression, and other data compression methods.

Proprietary Standards

In addition to the industry-standard protocols for modulation, error correction, and data compression that are generally defined and approved by the ITU-T, several protocols in these areas were invented by various companies and included in their products without any official endorsement by any standards body. Some of these protocols have been quite popular at times and became pseudo-standards of their own. The only

proprietary standards that continue to enjoy widespread support are the Microcom MNP standards for error correction and data compression. Others, such as 3Com's HST, CompuCom's DIS, and Hayes' V-series, are no longer popular. For details about the MNP classes, see "MNP Classes" in the Technical Reference section of the disc packaged with this book.

Note

For more information about older proprietary protocols, see [Chapter 18](#) of *Upgrading and Repairing PCs, 11th Edition*, included in electronic form on this book's disc.

56Kbps Modems

At one time, the V.34 annex speed of 33,600bps (33.6Kbps) was regarded as the absolute speed limit for asynchronous modem usage. However, starting in 1996, modem manufacturers began to produce modems that supported speeds of up to 56,000bps. These so-called "56K" or "56Kbps" modems are now universal, although the methods for breaking the 33.6Kbps barrier have changed several times. To understand how this additional speed was achieved, you must consider the basic principle of modem technology that is, the digital-to-analog conversion.

As you've learned, a traditional modem converts data from digital to analog form so it can travel over the Public Switched Telephone Network (PSTN). At the destination system, another modem converts the analog data back to its digital form. This conversion from digital to analog and back causes some speed loss. Even though the phone line is physically capable of carrying data at 56Kbps or more, the effective maximum speed because of the conversions is about 33.6Kbps. An AT&T engineer named Claude Shannon came up with a law (Shannon's Law) stating that the maximum possible error-free data communications rate over an all-analog PSTN is approximately 35Kbps, depending on the noise present.

However, because many parts of the United States's urban telephone system is digital being converted to analog only when signals reach the telephone company's central office (or central switch) it's possible to "break" Shannon's Law and achieve faster download rates. You can, in some cases, omit the initial digital-to-analog conversion and send a purely digital signal over the PSTN to the recipient's CO (see [Figure 17.8](#)). Thus, only one digital-to-analog conversion is necessary, instead of two or more. The result is that you theoretically can increase the speed of the data transmission, in one direction only, beyond the 35Kbps specified by Shannon's Law to nearly the 56Kbps speed supported by the telephone network. Prior to the new ITU V.92 standard, the transmission in the other direction was still limited to the V.34 annex maximum of 33.6Kbps. However, both the modem and the ISP must have support for the ITU V.92 standard to overcome this limitation for uploading speeds.

Figure 17.8. V.90-based 56Kbps connections enable you to send data at standard analog modem rates (33.6Kbps maximum) but enable you to receive data nearly twice as fast, depending on line conditions.

▶▶ See "[ITU V.92 and V.44 Breaking the Upload Barrier](#)," p. [1085](#), for more information on how the V.92 standard enables faster uploading.

56Kbps Limitations

Thus, 56Kbps modems can increase data transfer speeds beyond the limits of V.34 modems, but they are subject to certain limitations. Unlike standard modem technologies, you can't buy two 56Kbps modems, install them on two computers, and achieve 56Kbps speeds. One side of the connection must use a special digital modem that connects directly to the PSTN without a digital-to-analog conversion.

Therefore, 56Kbps modems can be used at maximum speeds only to connect to ISPs or other hosting services that have invested in the necessary infrastructure to support the connection. Because the ISP has the digital connection to the PSTN, its downstream transmissions to your computer are accelerated. If both sides of the connection support standards predating V.92, your communications back to the ISP are not accelerated.

On a practical level, this means you can surf the Web and download files more quickly, but if you host a web server on your PC, your users will realize no speed gain because the upstream traffic is not accelerated unless you and your ISP both use V.92-compliant modems. If you connect to another regular modem, your connection is made at standard V.34 annex rates (33.6Kbps or less).

Also, only one digital-to-analog conversion can be in the downstream connection from the ISP to your computer. This is dictated by the nature of the physical connection to your local telephone carrier. If additional conversions are involved in your connection, 56Kbps technology will not work for you; 33.6Kbps will be your maximum possible speed.

Note

Although most advertising for 56Kbps modems refers to them as simply "56K" modems, this is inaccurate. "K" is most often used in the computer business to refer to kilobytes. If that were true, a "real" 56K modem would be downloading at 56,000 bytes per second (or 448,000 bits per second)!

With the way the telephone system has had to grow to accommodate new exchanges and devices, even

neighbors down the street from each other might have different results when using a 56Kbps modem.

Caution

56Kbps modem communications are highly susceptible to slowdowns caused by line noise. Your telephone line might be perfectly adequate for voice communications and even lower-speed modem communications, but inaudible noise easily can degrade a 56Kbps connection to the point at which there is only a marginal increase over a 33.6Kbps modem, or even no increase at all. If you do have a problem with line noise, getting a surge suppressor with noise filtration might help.

Hotel connections through telephones with data jacks typically provide very slow connections with any type of modem. Even if you have a V.90- or V.92-compliant 56Kbps modem, you will be lucky to achieve even a 24Kbps transmission rate. The analog-to-digital conversions that occur between your room's telephone and the hotel's digital PBX system eliminate the possibility of using any of the 56Kbps standards the modem supports because they depend on a direct digital connection to the central switch (CS).

As an alternative, more and more hotels and motels provide Ethernet-based access to broadband Internet service; a growing number even provide wireless Ethernet access with Wi-Fi/IEEE-802.11b hardware. Depending on the location, you might be able to use your normal Ethernet card or connect to a USB adapter provided by the hotel. If you want high-speed Internet access as part of the package with your next hotel or motel stay, contact the specific lodging location or chain website for details and pricing.

Early 56Kbps Standards

To achieve a high-speed connection, both modems and your ISP (or other hosting service to which you connect) must support the same 56Kbps technology. The first 56Kbps chipsets were introduced in late 1996:

- U.S. Robotics's x2 used Texas Instruments (TI) chipsets.
- Rockwell's K56flex was supported by Zoom and other modem makers.

These rival methods for achieving performance up to 56Kbps were incompatible with each other and were replaced in 1998 by the ITU's V.90 standard.

Note

For more information about K56flex and x2, see *Upgrading and Repairing PCs, 11th Edition*, available in electronic format on the disc supplied with this book.

Unfortunately, the 56Kbps name is rather misleading, in regards to actual transmission speeds. Although all 56Kbps modems theoretically are capable of this performance on top-quality telephone lines, the power requirements for telephone lines specified in the FCC's Part 68 regulation limit the top speed of these modems to 53Kbps. The FCC has been considering lifting this speed limitation since the fall of 1998, but it

remains in place to date.

V.90

V.90 was introduced on February 5, 1998, and was ratified by the ITU-T on September 15, 1998. Its ratification ended the K56flex/x2 standards "war": Shortly thereafter, most modem manufacturers announced upgrade options for users of x2 and K56flex modems to enable these products to become V.90 compliant.

Some modem vendors offer upgrades for K56flex and x2 modems to the V.90 standard. If you purchased your modem before the V.90 standard became official, see your modem vendor's website for information about upgrading to V.90.

ITU V.92 and V.44Breaking the Upload Barrier

56Kbps protocols, such as the early proprietary x2 and K56flex and the ITU V.90 standard, increased the download speed from its previous maximum of 33.6Kbps to 56Kbps. However, upload speeds, which affect how quickly you can send email, page requests, and file transfers, were not affected by the development of 56Kbps technologies. Upload speeds with any of these 56Kbps technologies are limited to a maximum of 33.6Kbps. This causes severe speed lags for both pure dialup users and those who depend on dialup modems for upstream traffic, such as users of one-way broadband solutionsfor example, one-way (Telco Return) cable modems, one-way DirecWAY, and one-way (Telco Return) fixed-base wireless Internet services. Other shortcomings of existing 56Kbps technology include the amount of time it takes the user's modem to negotiate its connection with the remote modem and the lack of uniform support for call-waiting features.

In mid-2000, the ITU unveiled a multifaceted solution to the problem of slow connections and uploads: the V.92 and V.44 protocols (V.92 was previously referred to as V.90 Plus).

V.92, as the name implies, is a successor to the V.90 protocol, and any modem that supports V.92 also supports V.90. V.92 doesn't increase the download speed beyond the 56Kbps barrier, but offers these major features:

- *QuickConnect.* QuickConnect cuts the amount of time needed to make a connection by storing telephone line characteristics and using the stored information whenever the same phone line is used again. For users who connect to the Internet more than once from the same location, the amount of time the modem beeps and buzzes to make the connection will drop from as much as 27 seconds to about half that time. Bear in mind, though, that this reduction in connection time does not come about until after the initial connection at that location is made and its characteristics are stored for future use.
- *Modem-on-Hold.* The Modem-on-Hold feature allows the user to pick up incoming calls and talk for a longer amount of time than the few seconds allowed by current proprietary call-waiting modems. Modem-on-Hold enables the ISP to control how long you can take a voice call while online without interrupting the modem connection; the minimum amount of time supported is 10 seconds, but longer amounts of time (up to unlimited!) are also supported by this feature. Modem-on-Hold also allows you to make an outgoing call without hanging up the modem connection. Modem-on-Hold, similar to previous proprietary solutions, requires that you have the call-waiting feature enabled on your telephone line and also requires that your ISP support this feature of V.92.
- *PCM Upstream.* PCM Upstream breaks the 33.6Kbps upload barrier, boosting upload speed to a maximum of 48Kbps. Unfortunately, because of power issues, enabling PCM Upstream can reduce your downstream (download) speed by 1.3Kbps2.7Kbps or more. PCM Upstream is an optional feature of V.92, and ISPs who support V.92 connections might not support this feature.

Modems that support V.92 typically also support the V.44 data-compression standard. V.44, which replaces V.42bis, provides for compression of data at rates up to 6:1 that's more than 25% better than V.42bis. This enables V.92/V.44 modems to download pages significantly faster than V.90/V.42bis modems can at the same connection speed.

Note

Although Modem-on-Hold is good for the Internet user with only one phone line (because it allows a single line to handle incoming as well as outgoing calls), it's not as good for ISPs because when you place your Internet connection on hold, the ISP's modem is not capable of taking other calls. ISPs that support Modem-on-Hold might need to add more modems to maintain their quality of service if this feature is enabled. More modems are necessary because the ISP won't be able to count on users dropping their Internet connections to make or receive voice calls when Modem-on-Hold is available.

When will you be able to enjoy the benefits of V.92/V.44? Although most major modem vendors have been offering V.92/V.44-compliant modems since late 2000, ISP interest in this standard has been tepid. Only one national ISP, Navipath (which provided support for many local and regional ISPs), offered V.92 access in 2001, and Navipath went out of business in September 2001. Prodigy began to offer V.92 service early in 2002.

According to the V.92 News & Updates page at Richard Gamberg's Modemsite (www.modemsite.com/56K/v92s.htm), many vendors of ISP equipment continue to drag their feet on V.92/V.44 support, in part because it often requires expensive upgrades to terminal equipment. Even after upgrading to support V.92/V.44, some existing terminal hardware is incapable of working with the desirable PCM Upstream feature. Additionally, many major modem vendors have produced so-called "V.92" modems that don't support major V.92 features. Check user reviews available at the Modemsite website and others before you buy a particular V.92 modem model.

Tip

Wondering whether it's time to get a V.92/V.44 modem? Before you update your current model or buy a new modem, do the following:

- Contact your ISP to see whether (or when) it plans to support V.92/V.44 and to determine which features will be supported.
- Check the V.92 ISPs listing at (www.v92.com) and contact ISPs in your area for more details.

Although the change from x2/K56flex to V.90 was a no-cost one for many modem owners, the upgrade from V.90 to V.92/V.44 isn't as painless. In many cases, only the most recent V.90 modems will be eligible for a free upgrade to V.92/V.44 firmware. Contact your modem vendor for details.

Can your existing V.90-compatible modem be upgraded to V.92/V.44? As with earlier 56Kbps modem standards, the answer will likely be, "It depends." Some Lucent LT Winmodem (Agere Systems) modem

drivers for V.90 also might include V.92 commands; see Modemsite's Lucent modem section for the latest information (<http://www.modemsite.com/56k/ltwin.asp>). For modems based on other chipsets, check with your modem vendor.

As with earlier 56Kbps standards, you shouldn't worry about V.92/V.44 support until your ISP announces that it is supporting these standards. Because the V.92 standard has several components, find out which features of V.92 your ISP is planning to support before you look into a modem firmware update or modem replacement.

Fax Modem Standards

Even though the first experimental facsimile equipment was developed at the end of World War II, it took many years for faxing to become commonplace. Similarly, the first fax boards for computers were not introduced until the late 1980s as separate devices. Later, fax capabilities were incorporated into modems. Today, virtually all modems also meet the ITU-T Class 3 fax standards, enabling them to send data to and receive data from other ITU-T Class 3 fax machines and multifunction devices.

Many recent multifunction devices also support the newer ITU-T.30E recommendation for color faxing. Fax modems don't meet this standard as shipped from the manufacturer, but you can download free color fax software developed by HP (Impact ColorFax) that works with most fax modems. Find Impact ColorFax at the BlackICE Software website (www.blackice.com).

For more information about ITU-T fax protocols, see "ITU-T Fax Protocols" in the Technical Reference on the disc packaged with this book.

Dialup Modem Recommendations

A dialup modem for a PC can take the form either of an external device with its own power supply that plugs into a PC's serial port or USB port or of an internal expansion card you insert into a PCI or PC Card bus slot inside the computer. Very few ISA-slot dialup modems are still on the market because the majority of recent systems no longer have ISA slots.

External versions of dialup modems are slightly more expensive because they include a separate case and power supply and sometimes require you to buy a serial modem cable or USB cable. The decision as to which type to use should typically depend on whether you have a free bus slot or serial port, whether you have USB ports and Windows 98/Me/2000/XP, how much room you have on your desk, the capabilities of your system's internal power supply, and how comfortable you are with opening up your computer.

I often prefer external modems because of the visual feedback they provide through their LED indicator lights. These lights let you easily see whether the modem is still connected and transmitting or receiving data. However, Windows and many communication programs today include onscreen indicators that provide some of the same information.

In many situations, however, an internal modem is preferable. If you are using an older computer whose serial ports do not have buffered UART chips, such as the 16550, some more advanced controller-based internal modems include an onboard 16550 UART-equivalent controller chip. This onboard UART with the modem saves you the trouble of upgrading the UART serial port. However, controller-less (or "Windows") modems do not include such chips and rely on the processor for their power and speed, which can degrade the performance of other applications while online. External 56Kbps modems can be hampered from achieving their full speeds by the limitations of the computer's serial port. An external USB model or an

internal model using the PCI slot might be preferable instead. Use [Table 17.5](#) to see how internal and external units compare.

Table 17.5. External Versus Internal Modems

Features	External	Internal
Price	Higher	Lower
Extras required	Serial or USB cable	Nothing
Migration between systems	Easy	Difficult (must open case)
Power supply	External AC adapter brick	Nonpowered by host bus
Status monitoring	External signal LEDs	Tray icon or none
Interface	Serial or USB	PCI or ISA

Although late versions of Windows 95 OSR 2.x have USB support, many USB devices actually require Windows 98 or better. Use Windows 98/Me/2000/XP to achieve more reliable support for USB devices.

▶▶ See "[UARTs](#)," p. [997](#).

Not all modems that function at the same speed have the same functionality. Many modem manufacturers produce modems running at the same speed but with different feature sets at different price points. The more expensive modems usually support advanced features, such as distinctive ring support, caller ID, voice and data, video teleconferencing, and call-waiting support. When purchasing a modem, be sure it supports all the features you need. You also should make sure the software you plan to use, including the operating system, has been certified for use with the modem you select.

If you live in a rural area, or in an older city neighborhood, your telephone line quality might influence your decision. Look at comparison test results carefully and pay particular attention to how well various modems perform with noisy lines. If your phone line sounds crackly during a rainstorm, that poor-quality line makes reliable modem communications difficult, too, and it can limit your ability to connect at speeds above 33.6Kbps.

Another feature to consider is the modem's resistance to electrical damage. Some brands feature built-in power protection to shield against damage from digital telephone lines (higher powered and not compatible with modems) or power surges. However, every modem should be used with a surge protector that allows you to route the RJ-11 telephone cable through the unit for protection against high-voltage surges.

All modems on the market today support V.90 or V.92, and even if your particular location can't support those speeds, your modem might still offer advanced features, such as voicemail or simultaneous voice and data. Keep in mind that V.90/V.92 connections seem to work better for many users if their modems also support x2. If you prefer a modem made by a vendor that also supports K56flex, try to buy a modem that contains both types of standards in its firmware (referred to by some vendors as "Dualmode" modems).

Choosing to Upgrade

If you bought your modem in 1997 or later, or if it was included in your computer, chances are good that it came with 56Kbps support or that you've upgraded it to some form of 56Kbps support. However, even though today's V.90/V.92 modems still have the same maximum speed, other changes in modem design have occurred that might make a modem upgrade desirable for you. And if you are still using a 33.6Kbps modem or even slower model, you should get a 56Kbps modem if your line quality can support it.

Dialup modems introduced from 2001 to the present still run at the 53Kbps FCC maximum with the potential to run at up to 56Kbps if the FCC regulations change, but they might offer one or more of the following advanced features:

- *MNP10EC support.* Improves performance on poor-quality phone lines by quickly adjusting line speed up and down with changing conditions. MNP10EC includes MNP10 and is superior.
- *PCI bus.* Newer systems don't have ISA slots. It can share IRQs. Unfortunately, most PCI modems are WinModems; see "[Modems Without a UART \(WinModems\)](#)," later in this chapter.
- *USB connection.* Most new systems include USB, but some no longer include serial ports. Requires Win98 or better.
- *Game-optimized.* Provides faster ping response for gaming but is not as useful for ordinary web surfing. These modems are more expensive than others.
- *Modem-on-hold.* Allows you to answer the phone and not lose the modem connection. Maximum hold time might be limited.
- *V.92/V.44 support.* Includes faster negotiation, modem-on-hold, and 56Kbps support. Not all ISPs have full V.92/V.44 support.
- *Voice support.* Allows the digitizing of received calls for answering machine functionality.

Modems Without a UART (WinModems)

Modems without a UART chip, sometimes referred to as *WinModems* after the pioneering U.S. Robotics version, can save you money at purchase time but can cause problems with speed and operating-system compatibility later.

For users wanting an inexpensive internal modem, a modem that doesn't use a traditional UART instead of a UART-equipped internal or external modem looks like a great deal, often costing less than \$40, compared to \$80 or more for a UART-equipped "hardware" modem. But, there is no free lunch for modem users. What can you lose with a modem that lacks a UART?

First, you need to realize that there are actually two types of UART-less modems: those that rely on Windows and the CPU for all operations (these modems are also called *controllerless* modems) and those that use a programmable digital signal processor (DSP) chip to replace the UART. Both types of modems use less power than traditional UART-based modems, making them better for use with notebook computers. Although both are "software modems," there's an enormous difference in what you're getting.

A Windows-based modem must run under Windows because Windows provides the brains of the modem, a cost-cutting move similar to that used by some low-cost host-based printers. You should avoid this if you're planning to try Linux, move the modem to a Macintosh, or use an old MS-DOSbased communications program. If you have no drivers for your modem/operating system combination, you'll have no luck using the software modem.

Software modems that lack a DSP have a second major strike against them: They make your CPU do all the work. Although today's computers have much faster CPUs than those required for typical software modems

(Pentium 133 minimum), your modem can still slow down your computer if you multitask while downloading or surfing the Web.

Most of the modems bundled with computer systems are software modems, and the major chipsets used include Lucent LT (now Agere Systems), Conexant (formerly Rockwell) HCF, U.S. Robotics WinModem, ESS Technology's HSP-compliant chipsets, Intel's Modem Silicon Operation (formerly Ambient), and PCTel.

Except for U.S. Robotics, the other companies produce chipsets that can be found in the modems made by many manufacturers.

For best results, do the following:

- *Make sure your modem uses a DSP.* Typically, these modems don't require a particular CPU or a particular speed of CPU.
- *Consider modems built around the Lucent/Agere LT chipset.* These modems have a DSP, and Lucent/Agere's firmware is frequently revised to achieve the best results in a rapidly changing telephony environment.
- *Use the modem manufacturer's own drivers first.* But software modems can often use any manufacturer's drivers for the same chipset with excellent results; in particular, Lucent/Agere LT chipset modems typically can use any Lucent/Agere LT driver from any modem manufacturer.
- *Don't delete the old software driver when you download and install new modem software.* As with UART-equipped modems, the latest firmware isn't always the best.
- *Look carefully at the CPU, RAM, and operating system requirements before you buy your modem.*

Tip

Many manufacturers sell both traditional and UART-free modems. If you have an older system or want the option to use MS-DOS or Linux-based communications programs, the hardware modem with a traditional UART might cost more but be a better choice.

Finding Support for "Brand-X" Modems

Many computer users today didn't install their modems, or even purchase them as a separate unit. Their modems came bundled inside the computer and often have a bare-bones manual that makes no mention of the modem's origin or where to get help. Getting V.90 firmware updates, drivers, or even jumper settings for OEM modems such as this can be difficult.

One of the best websites for getting help when you don't know where to start is the "Who Made My Modem?" page (www.56K.com), which features

- Links to the FCC's equipment authorization database (enter the FCC ID to locate the vendor)
- Using ATI commands to query the modem chipset
- Lookup by chipset manufacturer
- Search engine tips
- Links to major modem and chipset manufacturers

Squeezing Performance from Your 56Kbps Modem

Although many users of 56Kbps modems have seen significant improvements in their connect speeds and throughputs over their previous V.34-type modems, many have not or have seen only sporadic improvements. According to the research of Richard Gamberg, available online at his Modemsite website (<http://www.modemsite.com>), a combination of five factors comes into play to affect your ability to get reliable connections in the range of 45Kbps-53Kbps (the current FCC maximum):

- The modem
- The modem firmware/driver
- Your line conditions
- The ISP's modems
- The ISP's modem firmware

It's up to you to ensure that you match your modem's 56Kbps type to the 56Kbps standards your ISP supports, and that you use the best (not always the latest!) modem firmware and drivers, as discussed in the previous section.

Other modem adjustments recommended by Modemsite include

- Modifying existing modem .INF files used by Windows 9x to accurately reflect connection speed
- Disabling 56Kbps connections (!) when playing games to minimize lag times

Note

This last suggestion might seem odd, but "fast" modems are designed to push a large amount of data through for downloads, and gameplay over modems actually deals with small amounts of data instead. The lag time caused by 56Kbps data handling can make a regular "fast" modem seem slow. If you want a fast modem for both downloading and game playing, see "[Choosing to Upgrade](#)," earlier in this chapter.

The site also hosts a forum area for discussing modem configuration, reliability, and performance issues.

Telco "Upgrades" and Your Modem

In addition to the well-known analog-to-digital conversion issue that prevents some phone lines from handling 56Kbps modems at anything beyond 33.6Kbps, other local telephone company (telco) practices and services can either prevent 56Kbps from ever working or take it away from you after you've enjoyed it for a while.

If you were getting 45Kbps or faster connections with your 56Kbps modem but can no longer get past 33.6Kbps, what happened? Some local telephone companies have been performing network "upgrades" that improve capacity for voice calls but prevent 56Kbps modems from running faster than 28Kbps. The cause seems to be the telephone companies' change from a signaling type called RBS (Robbed Bit Signaling) to SS7 (Signaling System 7), which changes how data used by the modem for high-speed access is detected. Caller ID devices connected to your phone line use RBS or SS7 signals to obtain information from incoming phone calls. If you use a caller ID box on the same phone circuit as your modem (even if it's connected in another room), you might not be able to get fast connections, or you might experience frequent disconnects. If you notice a drop in connection speed or reliability after you install caller ID, disconnect the caller ID box from the wall jack while you're online and see whether the speed and reliability

of your modem connections improve.

What else can you do? You can install the latest firmware available for your modem model or chipset. You can also check with your local telephone company to see whether it can update its firmware to solve the problem. Even if your modem has different firmware, checking on an upgrade might still be useful because this problem is likely to become widespread as telephone numbers, exchanges, and area codes continue to multiply like weeds and telephone network upgrades must keep pace.

Sharing Your Internet Connection

Whether you have a 56Kbps dialup modem or a broadband connection, one connection is often not enough for a home or small-office setting. You can share your connection with other computer users with one of the following methods:

- *Computer-based sharing solutions.* These work by connecting the computer with Internet access to a network with the other computers with which you want to share the connection. The computer with the connection acts as a gateway to the Internet.
- *Router-based sharing solutions.* These work by connecting all the computers on a network with a router or gateway connected to the Internet. Most routers are designed to work with broadband devices that use a USB or 10BASE-T connection, but a few work with dialup modems.

Typical computer-based sharing solutions include

- *Microsoft Internet Connection Sharing (ICS).* Introduced in Windows 98 Second Edition (Win98SE) and also a part of Windows Me, Windows 2000, and Windows XP
- *Third-party gateway or proxy-server programs such as Wingate, Winproxy, and others*

Both ICS and third-party programs can also work with non-Windows computers because the TCP/IP network protocol, the standard protocol of the Internet, is used for networking.

▶▶ See "[Network Protocols](#)," p. [1129](#), for details of the TCP/IP protocol.

Router-based solutions are available for popular types of home and small-office networks, including:

- Wired Ethernet
- IEEE 802.11b and 802.11g wireless (Wi-Fi) Ethernet
- HomePNA (phone-line) networks

Comparing Gateways, Proxy Servers, and Routers

To the typical user, it doesn't matter whether a gateway, proxy server, or router is used to provide shared Internet access. Traditional gateway programs such as Microsoft ICS, Sygate Home Network, and WinGate use a method of shared access called Network Address Translation (NAT), which enables sharing by converting network addresses into Internet-compatible addresses during the file request and download process. This process requires little client PC configuration but doesn't permit page caching, content filtration, firewalls, or other useful services that can be provided by a proxy server. Proxy servers traditionally have required tricky configurationsometimes at an individual application level. However, products such as WinProxy combine the ease of configuration of a gateway with the extra features of a proxy server.

Popular third-party sharing programs include WinProxy (www.winproxy.com), WinGate (www.wingate.com), and SyGate (www.sygate.com). Many home-oriented networks and modems are bundled with these or similar products, so if you're in the market for a new modem or are building a small network, ask

whether a proxy server or gateway program for Internet sharing is included. If not, you can download free trial versions from the previously listed websites.

If you don't like leaving a computer on at all times to provide Internet access to the network, a router is the only way to go. Routers also provide better firewall protection for all computers on the network, and some, such as certain Linksys models, can be configured to require networked PCs to be running specified firewall or antivirus software before Internet access is granted. The most common routers for broadband Internet access also contain a switch, so you won't need a separate connection device for your home network.

Routers for Internet Sharing

Just as an ICS gateway has two IP addresses—one for the network and one for the Internet—so does a router. Most routers are sold for use with two-way broadband Internet access devices such as two-way cable modems and fixed wireless broadband services or DSL lines. Most of these devices connect to the computer via a 10BASE-T Ethernet port, as seen in [Figure 17.9](#).

Figure 17.9. Front (top) and rear (bottom) views of a typical broadband router with a built-in four-port switch, the Linksys EtherFast Cable/DSL Router, BEFSR41. *Top photo courtesy Linksys.*

1. LAN port #1
2. LAN port #2
3. LAN port #3
4. LAN port #4
5. WAN port (connects to cable or DSL modem)
6. Uplink port (connects to a hub or switch to allow additional users to connect to the Internet)

When you use a router to share your Internet connection, the WAN port on the router replaces the network card connection originally used to connect your computer with the cable modem or DSL modem. All computers on the network connect to LAN ports and can share files and printers with each other as well as share Internet access.

The router can be configured to provide either dynamically assigned or fixed IP addresses to each computer connected to it through the LAN ports and can be configured to use the same MAC address (a unique hardware address assigned to each network component) originally used by the network card first connected to the cable modem or DSL modem. This prevents the ISP from determining that you're sharing the connection. The WAN port on the router can be configured to obtain an IP address from the cable modem or DSL modem or to have a fixed IP address, depending on the configuration required by the ISP.

As long as the router is running and properly connected to the cable modem or DSL modem, any computer connected to it can go online just by opening its email client or web browser.

[Figure 17.10](#) shows a typical Ethernet home network configuration that uses a router with a built-in switch to share a cable modem.

Figure 17.10. When you use a router to share a cable modem or DSL modem, you need only one network card in each computer. This router incorporates a switch that can connect up to four computers to the cable modem.

If you have a wireless network, connect the wireless access point or gateway device designed for your network to the cable modem or other broadband Internet device (some also work with dialup modems). The wireless access point or gateway device will transfer data to and from computers on the wireless network and the Internet.

For more information about choosing and installing wired and wireless networks, see [Chapter 18](#).

Internet Troubleshooting

This section deals with hardware problems that can cause Internet problems. Software problems usually are caused by incorrect configuration of the TCP/IP protocol required by all types of Internet connections. For more information about TCP/IP or other software problems, see [Chapter 18](#).

Diagnosing Problems with a Shared Internet Connection

Although each Internet sharing product has individual configuration issues, the following tips provide general guidelines useful for solving problems with all of them.

Check Your Host Configuration

If your host isn't set up correctly, it can't share its connection with clients. Check the bindings for TCP/IP or other protocols used to create the shared connection. If you are using Microsoft's ICS and two Ethernet cards, you will see entries in the Network configuration on the host computer for each Ethernet card and for the ICS software itself.

Check Your Client Configuration

Make sure your clients have correct TCP/IP, DHCP, and other protocol settings for the host. The **ping** command can be used at a command prompt to check the Internet connection; try pinging a website by opening a Windows command prompt and typing a command such as **ping** www.dslreports.com. Note that many sites are designed to reject ping requests, in which case you receive timeout errors.

If you have a working Internet connection and are pinging a site not designed to reject ping requests, you should see the IP address for the website you specify and the round-trip time (or ping rate) for four signals sent to the website. If you are pinging a site that normally responds and yet you still get no response or see an error message, you might have a configuration problem with your TCP/IP configuration.

Note

Because pinging can also be used for denial-of-service (DoS) attacks by hackers on websites, some websites don't respond to pings. Use **ping** when your system is working properly to find a website that will respond to **ping** and use that site for troubleshooting as described previously.

Verify that the host has a working Internet connection that's active before you try to share it. Check the sharing program's documentation to see how guests can dial the host's modem to start a connection if necessary.

Speed Will Drop with Multiple Users

It's normal for the speed of an Internet connection to drop with multiple users, but if you're concerned about the degree of decline, check with the sharing software provider for Registry tweaks and other options to improve performance.

Diagnosing Connection Problems with Signal Lights

Signal lights are found on most external broadband devices, such as cable modems, wireless broadband routers, and DSL modems. The signal lights indicate whether the unit is receiving signals from the computer, sending data to the network, or receiving data from the network and whether the unit can "see" the network even if no data is currently flowing through the unit.

On many units, the power light also is used to indicate problems. If the light is normally green, for example, a red light might indicate the unit has failed. Other lights flash when data is being sent or received. On cable modem or wireless broadband routers, look for a signal lock light; this light flashes if the unit is trying to lock onto a signal from the cable network or wireless transmitter.

Learn the meaning of the lights on your broadband device to help you diagnose problems; the user manual or vendor's website will provide the troubleshooting information you need for the particular broadband device you use.

Modem Fails to Dial

1.

Check line and phone jacks on the modem. Use the line jack to attach the modem to the telephone line. The phone jack takes the same RJ-11 silver cord cable, but it's designed to let you daisy-chain a telephone to your modem, so you need only a single line for modem and telephone use. If you have reversed these cables, you will not get a dial tone.

2.

If the cables are attached properly, check the cable for cuts or breaks. The outer jacket used on RJ-11 telephone cables is minimal. If the cable looks bad, replace it.

3.

If the modem is external, make sure the RS-232 modem cable is running from the modem to a working serial port on your computer and that it is switched on. Signal lights on the front of the modem can be used to determine whether the modem is on and whether it is responding to dialing commands.

4.

If the modem is a PC Card (PCMCIA card), make sure it is fully plugged into the PCMCIA/PC slot. With Windows 9x/Me/2000/XP, you should see a small PCMCIA/PC Card icon on the toolbar. Double-click it to view the cards that are currently connected. If your modem is properly attached, it should be visible. Otherwise, remove it, reinsert it into the PCMCIA/PC Card slot, and see whether the

computer detects it.

5.

Make sure your modem has been properly configured by your OS. With Windows 9x/Me/2000, use the Modems control panel to view and test your modem configuration (with Windows XP, you can use the Modem Troubleshooter). Select your modem and click the Diagnostics tab. This displays the COM (serial) ports in your computer. Select the COM port used by the modem, and click the More Info tab. This sends test signals to your modem. A properly working modem responds with information about the port and modem.

6.

If you get a **Couldn't Open Port** error message, your modem isn't connected properly. It might be in use already by a program running in the background, or there might be an IRQ or I/O port address conflict with another card in your computer. Whether you have a modem installed, every COM port that is working will display its IRQ, I/O port address, and UART chip type when you run Diagnostics. The UART type should be 16550 or above for use with any modern modem.

Connecting a PC Card Modem via a Dongle

Some PC Card modems do not use a standard RJ-11 cable because the card is too thin. Instead, they use a connection called a *dongle*, which runs from the PC Card to the telephone. If this proprietary cable is damaged, your modem is useless. You should purchase a spare from the modem vendor and carry it with you. And if you find the dongle is too short to reach the data jacks in a hotel room, buy a coupler from your local RadioShack or telephone-parts department and attach a standard RJ-11 cable to your dongle via the coupler. Dongles are also used with some PC Card network cards for the same reason; the RJ-45 twisted-pair cable connector is too wide to attach to a standard PC Card. To avoid using dongles, look for a network or modem card that has a standard RJ-11 or RJ-45 connection built in to it.

Note

You can also test your modem response by setting up a HyperTerminal session (discussed earlier) to send the modem commands. If the modem fails to respond, this is another indication of a problem with the modem-PC connection.

Computer Locks Up After Installing or Using Internal Modem, Terminal Adapter, or Network Card

The usual cause of lockups after you install an internal card is an IRQ conflict. Internal dialup modems that use ISA slots typically cause the "curse of the shared IRQ," especially if a serial mouse is also used. PC Card and PCI modems can share IRQs safely, and USB mice use the same IRQ as the USB port itself. For

more information about shared IRQs with ISA modems and serial mice, see the Technical Reference section on the disc packaged with this book.

Computer Can't Detect External Modem

1.

Make sure the modem has been connected to the computer with the correct type of cable.

For external modems that use an RS-232 serial port, you might need a separate RS-232 modem cable, which has a 9-pin connector on one end (to connect to the computer) and a 25-pin connector on the other end (to connect to the modem). Some external modems have an integrated modem cable. Because RS-232 is a very flexible standard encompassing many pinouts, be sure the cable is constructed according to the diagram on the following page.

If you purchase an RS-232 modem cable prebuilt at a store, you'll have a cable that works with your PC and your modem. However, you can use the preceding chart to build your own cable or, by using a cable tester, determine whether an existing RS-232 cable in your office is actually made for modems or some other device.

PC (with 9-pin COM portmale)		Modem (25-pin portfemale)	
3	TX data	2	
2	RX data	3	
7	RTS	4	
8	CTS	5	
6	DSR	6	
5	SIG GND	7	
1	CXR	8	
4	DTR	20	
9	RI	22	

2.

Make sure the COM (serial) port or USB port to which the modem is connected to is working.

The Windows 9x/Me/2000/XP diagnostics test listed earlier can be useful in testing the serial port, but third-party testing programs such as AMIDIAG have more thorough methods for testing the system's COM ports. These programs can use loopback plugs to test the serial ports. The loopback plug loops signals that would be sent to the modem or other serial device back to the serial port. These programs normally work best when run from the MS-DOS prompt.

Some diagnostics include a loopback plug to test serial ports. Loopback plugs may vary in design depending on the vendor.

To ensure that the USB port is working, check the Device Manager in Windows; a working USB port is listed as a USB Root hub and a PCI to USB Universal Host Controller in the Universal Serial Bus device category. Any external USB hubs also are listed in the same category. If this category is not listed and the ports are physically present on the computer, make sure you are using Windows 98/Me/2000/XP (only a few late versions of Windows 95 have USB support). If you are, be sure the USB ports are enabled in the system BIOS.

3.

Check the power cord and power switch.

Using Your Modem Sound to Diagnose Your Modem

If you listen to your modem when it makes a connection, you might have realized that different types of modems make distinctive connection sounds and that different connection speeds also make distinctive sounds.

The various types of 56Kbps modems have distinctly different handshakes of tones, buzzes, and warbles as they negotiate speeds with the ISP's modem. Learning what your modem sounds like when it makes a 56Kbps connection and when it settles for a V.34-speed connection can help you determine when you should hang up and try to connect at a faster speed.

The Modemsite's troubleshooting section has a number of sound samples of various modems during the handshaking process. Use RealPlayer to play the samples, available at www.modemsite.com/56k/trouble.asp (click the Handshakes link).

Compare these sound samples to your own modem; be sure you adjust the speaker volume for your modem so you can hear it during the call.

Focus of This Chapter

This chapter concentrates on how to build and use a peer-to-peer network, the lowest-cost network that is still highly useful to small business and home-office users. This type of network can be created utilizing required network hardware along with any recent version of Windows, from Windows 9x and NT through Windows XP. As you'll see, most peer-to-peer networks can be "grown" into client/server networks at a later point by adding a dedicated server and the appropriate software to the server and client PCs.

Thus, this chapter provides the hands-on and practical information you need to create a small-office, workgroup, or home-office network. If you manage a corporate network using Linux, Unix, Windows Server, or Novell NetWare, you will also be concerned with matters such as security, user profiles, SIDs, and other factors beyond the scope of this book.

Note

Networking is an enormous topic. For more information about client/server networking, wide area networking, the Internet, and corporate networking, I recommend *Upgrading and Repairing Networks* from Que.

Defining a Network

A *network* is a group of two or more computers that *intelligently* share hardware or software devices with each other. A network can be as small and simple as two computers that share the printer and CD-ROM drive attached to one of them or as large as the world's largest network: the Internet.

Intelligently sharing means that each computer that shares resources with another computer or computers maintains control of that resource. Thus, a switchbox for sharing a single printer between two computers doesn't qualify as a network device; because the switchbox not the computers handles the print jobs, neither computer knows when the other one needs to print, and print jobs can interfere with each other.

A shared printer, on the other hand, can be controlled remotely and can store print jobs from different computers on the print server's hard disk. Users can change the sequence of print jobs, hold them, or cancel them. And, sharing of the device can be controlled through passwords, further differentiating it from a switchbox.

Virtually any storage or output device can be shared over a network, but the most common devices include

- Printers
- Disk drives
- Optical drives
- Modems
- Fax machines
- Tape backup units
- Scanners

Entire drives or just selected folders can be shared with other users via the network.

In addition to reducing hardware costs by sharing expensive printers and other peripherals among multiple users, networks provide additional benefits to users:

- Multiple users can share access to software and data files.
- Electronic mail (email) can be sent and received.
- Multiple users can contribute to a single document using collaboration features.
- Remote-control programs can be used to troubleshoot problems or show new users how to perform a task.
- A single Internet connection can be shared among multiple computers.

Types of Networks

Several types of networks exist, from small, two-station arrangements to networks that interconnect offices in many cities:

- *Local area networks.* The smallest office network is referred to as a local area network (LAN). A LAN is formed from computers and components in a single office or building. A LAN can also be built at home from the same components used in office networking, but, as you'll see later, special home-networking components now exist to allow the creation of what can be called a home area network (HAN).

- *Home area networks.* A home area network (HAN) is really no different from a LAN. It often uses the same hardware components as a LAN, but a HAN is mainly used to share Internet access. While wireless is often used in LANs, its usage has skyrocketed in the HAN environment. HANs are often referred to as small-office/home-office (SOHO) LANs.
- *Wide area networks.* LANs in different locations can be connected by high-speed fiber-optic, satellite, or leased phone lines to form a wide area network (WAN).
- *The Internet.* The World Wide Web is the most visible part of the world's largest network, the Internet. Although many users of the Internet still use modems over a dialup connection rather than a LAN or WAN connection, any user of the Internet is a network user. The Internet is really a network of networks, all of which are connected to each other through the TCP/IP protocol. It's a glorified WAN in many respects. Programs such as web browsers, File Transfer Protocol (FTP) clients, and email clients are some of the most common ways users work with the Internet.
- *Intranets.* Intranets use the same web browsers and other software and the same TCP/IP protocol as the public Internet, but intranets exist as a portion of a company's private network. Typically, intranets comprise one or more LANs that are connected to other company networks, but, unlike the Internet, the content is restricted to authorized company users only. Essentially, an intranet is a private Internet.
- *Extranets.* Intranets that share a portion of their content with customers, suppliers, or other businesses, but not with the general public, are called extranets. As with intranets, the same web browsers and other software are used to access the content.

Note

Both intranets and extranets rely on firewalls and other security tools and procedures to keep their private contents private.

Requirements for a Network

Unless the computers that are connected know they are connected and agree on a common means of communication and what resources are to be shared, they can't work together. Networking software is just as important as networking hardware because it establishes the logical connections that make the physical connections work.

At a minimum, each network requires the following:

- Physical (cable) or wireless (usually via radio-frequency) connections between computers
- A common set of communications rules, known as a *network protocol*
- Software that enables resources to be shared with other PCs and controls access to shared resources, known as a *network operating system*
- Resources that can be shared, such as printers, disk drives, and CD-ROMs
- Software that enables computers to access other computers with shared resources, known as a *network client*

These rules apply both to the simplest and the most powerful networks, and all the ones in between, regardless of their nature. The details of the hardware and software you need are discussed more fully later in this chapter.

About Wireless Networking

Various forms of wireless networks using either radio or IR (infrared) have been developed over the years, but until recently, the benefits of a wireless network (no wires to pull or holes to drill) were outweighed by the lack of standards and relatively slow speed. In conventional Ethernet networks, you can use various brands of NICs, hubs, and switches without any problems, as long as each device corresponds to the same Ethernet standard. That distinction, as you're likely well aware, has changed considerably.

Even though early forms of wireless networking were much slower than wired networks and often were single-vendor proprietary solutions, today's newest wireless networks offer speeds that range from being comparable to 10BASE-T to being nearly as fast as Fast Ethernet. Prices have also dropped dramatically, making wireless networking an increasingly appealing alternative to traditional wired network solutions.

Client/Server Versus Peer Networks

Although every computer on a LAN is connected to every other computer, they do not necessarily all communicate with each other. There are two basic types of LANs, based on the communication patterns between the machines: client/server networks and peer-to-peer networks.

Client/Server Networks

On a *client/server* network, every computer has a distinct role, that of either a client or a server. A *server* is designed to share its resources among the client computers on the network. Typically, servers are located in secured areas, such as locked closets or data centers (server rooms), because they hold an organization's most valuable data and do not have to be accessed by operators on a continuous basis. The rest of the computers on the network function as *clients* (see [Figure 18.1](#)).

Figure 18.1. The components of a client/server LAN.

A dedicated server computer typically has faster processors, more memory, and more storage space than a

client because it might have to service dozens or even hundreds of users at the same time.

High-performance servers typically use from two to eight processors (and that's not counting dual-core CPUs), have several gigabytes of memory installed, use the 64-bit version of the PCI expansion slot for server-optimized network interface cards, and have redundant power supplies. The server runs a special network operating system such as Windows Server, Linux, Unix, or Novell NetWare that is designed solely to facilitate the sharing of its resources. These resources can reside on a single server or on a group of servers. When more than one server is used, each server can "specialize" in a particular task (file server, print server, fax server, email server, and so on) or provide redundancy (duplicate servers) in case of server failure. For very demanding computing tasks, several servers can act as a single unit through the use of parallel processing.

A client computer typically communicates only with servers, not with other clients. A client system is a standard PC that is running an operating system such as Windows XP. These versions of Windows contain the client software that enables the client computers to access the resources that servers share. Older operating systems, such as Windows 3.x and DOS, require add-on network client software to join a network.

Peer-to-Peer Network

By contrast, on a peer-to-peer network, every computer is equal and can communicate with any other computer on the network to which it has been granted access rights (see [Figure 18.2](#)). Essentially, every computer on a peer-to-peer network can function as both a server and a client; any computer on a peer-to-peer network is considered a server if it shares a printer, a folder, a drive, or some other resource with the rest of the network. This is why you might hear about client and server activities, even when the discussion is about a peer-to-peer network. Peer-to-peer networks can be as small as two computers or as large as hundreds of systems. Although there is no theoretical limit to the size of a peer-to-peer network, performance drops significantly and security becomes a major headache on peer-based networks with more than 10 computers. Also, Microsoft imposes a 10-station limit on computers running Windows 2000 Professional or Windows XP Professional that are sharing resources with other systems. For these reasons, I recommend that you switch to a client/server network when your network climbs above 10 stations.

Figure 18.2. The logical architecture of a typical peer-to-peer network.

Peer-to-peer networks are more common in small offices or within a single department of a larger organization. The advantage of a peer-to-peer network is that you don't have to dedicate a computer to

function as a file server. Instead, every computer can share its resources with any other. The potential disadvantages to a peer-to-peer network are that typically less security and less control exist because users normally administer their own systems, whereas client/server networks have the advantage of centralized administration.

Comparing Client/Server and Peer-to-Peer Networks

Client/server LANs offer enhanced security for shared resources, greater performance, increased backup efficiency for network-based data, and the potential for the use of redundant power supplies and RAID drive arrays. Client/server LANs also have a much greater cost to purchase and maintain. [Table 18.1](#) compares client/server and peer-to-peer server networking.

Table 18.1. Comparing Client/Server and Peer-to-Peer Networking

Item	Client/Server	Peer-to-Peer
Access control	Via user/group lists of permissions; a user has access to only the resources granted, different users can be given different levels of access	Via password lists by resource; each resource requires a separate password, all-or-nothing access, no centralized user list
Security	High; access is controlled by user or by group identity	Low; knowing the password gives anybody access to a shared resource
Performance	High; the server is dedicated and doesn't handle other tasks	Low; servers often act as workstations
Hardware cost	High; specialized high-performance server hardware with redundancy features	Low; any workstation can become a server by sharing resources
Software cost	Higher; license fees per user are part of the cost of the server OS	Lower; client software is included with OS
Backup	Centralized on the server; managed network administrator, backup by device and media only required at server	Decentralized; managed by users, backup devices and media required at each workstation
Redundancy	Yes; duplicate power supplies, hot-swappable drive arrays, and even redundant servers are common; network OS normally is capable of using redundant devices automatically	No true redundancy among peer "servers" or clients; failures require manual intervention to correct, with a high possibility of data loss

Network Architecture Overview

The architecture on which you choose to base your network is the single most important decision you make when setting up a local area network. The architecture defines the speed of the network, the medium access control mechanism it uses, the types of cables you can use, the network interface adapters you must buy, and the adapter drivers you install in the network client software.

The Institute of Electrical and Electronic Engineers (IEEE) has defined and documented a set of standards for the physical characteristics of both collision-detection and token-passing networks. These standards are known as IEEE 802.3 (Ethernet) and IEEE 802.5 (Token-Ring). IEEE 802.11 (Wi-Fi) defines wireless versions of Ethernet.

Note

Be aware, however, that the colloquial names Ethernet and Token-Ring actually refer to earlier versions of these architectures, on which the IEEE standards were based. Minor differences exist between the frame definitions for true Ethernet and true IEEE 802.3. In terms of the standards, IBM's 16Mbps Token-Ring products are an extension of the IEEE 802.5 standard.

The most common choice today for new networks is Ethernet (both wired and wireless), although you might still see some Token-Ring installations in older environments. Other network data-link architectures you might encounter are summarized in [Table 18.2](#). The abbreviations used for the cable types are explained in the following sections.

Table 18.2. LAN Architecture Summary

Network Type	Speed	Maximum Number of Stations	Transmission Types	Notes
Ethernet	10Mbps	Per network: 1,024; per segment: 10BASE-T=2 10BASE-2=30 10BASE-5=100 10BASE-FL=2	Cable: UTP Cat 3 (10BASE-T), Thicknet (coax; 10BASE-5), Thinnet (RG-58 coax; 10BASE-2), fiber-optic (10BASE-F)	Largely replaced by Fast Ethernet; backward compatible with Fast or Gigabit Ethernet
Fast Ethernet	100Mbps	Per network: 1,024; per segment: 1	Cable: Cat 5 UTP	The most popular networking standard

Gigabit Ethernet	1,000Mbps	Per network: 1,024; per segment: 1	Cable: Cat 5/5e/6 UTP	Uses all four signal pairs in the cable
802.11a Wireless Ethernet	54Mbps	Per network: 1,024; per segment: n/a	RF 5GHz band (up to 75 ft. outdoors)	Dual-band hardware needed to connect with 802.11b or 802.11g
802.11b Wireless Ethernet	11Mbps	Per network: 1,024; per segment: n/a	RF 2.4GHz band (up to 150 ft. indoors)	Interoperable with 802.11g; dual-band hardware needed to connect with 802.11a
802.11g Wireless Ethernet	54Mbps	Per network: 1,024; per segment: n/a	RF 2.4GHz band (up to 150 ft. indoors)	Interoperable with 802.11b; dual-band hardware needed to connect with 802.11a
Token-Ring	4Mbps; 16Mbps; 100Mbps	72 on UTP; 250260 on type 1 STP	UTP, Type 1 STP, and fiber optic	Largely replaced by Fast Ethernet
ARCnet	2.5Mbps	255	RG-62 coax UTP/Type 1 STP	Obsolete for new installations; uses same cable as IBM 3270 terminals

A few years ago, the choice between Token-Ring or Ethernet wasn't easy. The original versions of standard Ethernet (10BASE-5 "Thick Ethernet" and 10BASE-2 "Thin Ethernet") used hard-to-install coaxial cable and were expensive to build beyond a certain point because of the technical limitations expressed by the "5-4-3" rule. This rule gets its name from the fact that Ethernet signals can travel through no more than five segments, four repeaters or hubs, and three populated segments (cable segments with two or more stations) before they become unreliable.

Initially, Token-Ring's 16Mbps version was substantially faster than 10BASE versions of Ethernet and had larger limits on the numbers of workstations permitted per segment. Currently, however, the popularity and low cost of Fast Ethernet; the use of easy-to-install twisted-pair cabling for standard, 100Mbps Fast, and even 1,000Mbps Gigabit Ethernet; and the use of hubs and switches to overcome classic Ethernet station limitations have made Fast Ethernet the preferred choice for networks of any size and that doesn't take into account the rising popularity of wireless Ethernet. It should also be noted that a properly designed Fast Ethernet network can be upgraded to Gigabit Ethernet in the future with a minimum of costs and hassle.

Wired Ethernet

With tens of millions of computers connected by Ethernet cards and cables, Ethernet is the most widely used data link layer protocol in the world. Ethernet-based LANs enable you to interconnect a wide variety of equipment, including Unix and Linux workstations, Apple computers, printers, and PCs. You can buy Ethernet adapters from dozens of competing manufacturers. Older adapters supported one, two, or all three of the cable types defined in the standard: Thinnet, Thicknet, and Unshielded Twisted Pair (UTP). Current adapters, on the other hand, typically support only UTP. Traditional Ethernet operates at a speed of 10Mbps, but the more recent (and most popular of the Ethernet flavors) Fast Ethernet standards push this speed to 100Mbps. The latest version of Ethernet, Gigabit Ethernet, reaches speeds of 1,000Mbps, or 100

times the speed of original Ethernet.

Note

Throughout the remainder of this chapter, be aware that discussion of older Ethernet solutions, such as those using Thicknet or Thinnet, or Token-Ring are only included for reference. You will usually work with these technologies only when installing new workstations or servers into older, existing networks. Most new network installations today use Gigabit, Fast, or Wireless Ethernet.

Fast Ethernet

Fast Ethernet requires adapters, hubs, switches, and UTP or fiber-optic cables designed to support the higher speed. Some early Fast Ethernet products supported only 10Mbps, but almost all current Fast Ethernet products are combination devices that run at both 10Mbps and 100Mbps, enabling you to gradually upgrade an older 10Mbps Ethernet network by installing new NICs and hubs over an extended period of time.

Both the most popular form of Fast Ethernet (100BASE-TX) and 10BASE-T standard Ethernet use two of the four wire pairs found in UTP Category 5 cable. An alternative Fast Ethernet standard called 100BASE-T4 uses all four wire pairs in UTP Category 5 cable, but this Fast Ethernet standard was never popular and is seldom seen today.

Gigabit Ethernet

Gigabit Ethernet also requires special adapters, hubs, switches, and cables. When Gigabit Ethernet was introduced, most installations used fiber-optic cables, but today it is just as common if not more common to run Gigabit Ethernet over the same Category 5 UTP (although better Cat 5e or Cat 6 is recommended) cabling that Fast Ethernet and newer installations of standard Ethernet use. Gigabit Ethernet for UTP is also referred to as 1000BASE-T.

Unlike Fast Ethernet and standard Ethernet over UTP, Gigabit Ethernet uses all four wire pairs. Thus, Gigabit Ethernet requires dedicated Ethernet cabling; you can't "borrow" two wire pairs for telephone or other data signaling with Gigabit Ethernet as you can with the slower versions. Most Gigabit Ethernet adapters can also handle 10BASE-T and 100BASE-TX Fast Ethernet traffic, enabling you to interconnect all three UTP-based forms of Ethernet on a single network.

Neither Fast Ethernet nor Gigabit Ethernet support the use of thin or thick coaxial cable originally used with traditional Ethernet, although you can interconnect coaxial-cable-based and UTP-based Ethernet networks by using media converters or specially designed hubs and switches.

Note

For more information about Ethernet, Fast Ethernet, Token-Ring, and other network data-link standards, see the "Data Link Layer Protocols" and "High-Speed Networking Technologies" sections found in [Chapter 19](#) of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the disc provided with this book.

Wireless Ethernet

The most common forms of wireless networking in the United States and Canada are built around various versions of the IEEE 802.11 wireless Ethernet standards, including IEEE 802.11b, IEEE 802.11a, and the newer (and more popular) IEEE 802.11g standard.

Wireless Fidelity (Wi-Fi) is a logo and term given to any IEEE 802.11 wireless network product certified to conform to specific interoperability standards. Wi-Fi Certification comes from the Wi-Fi Alliance, a nonprofit international trade organization that tests 802.11-based wireless equipment to ensure it meets the Wi-Fi standard. To carry the Wi-Fi logo, an 802.11 networking product must pass specific compatibility and performance tests, which ensure that the product will work with all other manufacturers' Wi-Fi equipment on the market. This certification arose from the fact that certain ambiguities in the 802.11 standards allowed for potential problems with interoperability between devices. By purchasing only devices bearing the Wi-Fi logo, you ensure that they will work together and not fall into loopholes in the standards.

Note

The Bluetooth standard for short-range wireless networking, covered later in this chapter, is designed to complement, rather than rival, IEEE 802.11-based wireless networks. In Europe, HiperLAN, which has performance and frequency usage similar to that of 802.11a, is the wireless networking standard.

The widespread popularity of IEEE 802.11-based wireless networks has led to the abandonment of other types of wireless networking, including RadioLAN and HomeRF. RadioLAN now markets long-range antennas that work with 802.11a-based wireless networks.

Note

Although products that are certified and bear the Wi-Fi logo for a particular speed (IEEE standard), such as 802.11g, are designed and tested to work together, most vendors of SOHO wireless networking equipment have started shipping devices that also feature proprietary technologies to raise the speed of the wireless network even further. Linksys calls its solution SpeedBooster, for example, which is advertised as providing "performance increases of up to 30% from old 802.11g standards." Just beware that most, if not all, of these vendor-specific solutions are not interoperable with solutions from other vendors.

Wi-FiA Standard Upon a Standard

When the first 802.11b networking products appeared, compatibility problems existed due to certain aspects of the 802.11 standards being ambiguous or leaving loopholes. A group of companies formed an alliance designed to ensure that their products would work together, eliminating any ambiguities or loopholes in the standards. This was originally known as the Wireless Ethernet Compatibility Alliance (WECA) but is now known simply as the Wi-Fi Alliance (www.wi-fi.org). In the past, the term *Wi-Fi* has

been used as a synonym for IEEE 802.11b hardware. However, because the Wi-Fi Alliance now certifies other types of 802.11 wireless networks (802.11a and 802.11g, for example), the term *Wi-Fi* should always be accompanied by the frequency band (as in Wi-Fi 2.4GHz band) to make it clear which products will work with the device. Currently, the alliance has certified 802.11b, 802.11a, 802.11g, and dual-band (a/b/g) products.

Caution

Dual-band hardware can access the 802.11a, 802.11b, and 802.11g flavors of Wi-Fi. The newer 802.11g wireless standard has the speed of 802.11a but connects to 802.11b networks without special hardware. Be sure you find out which flavor of Wi-Fi is in use in a particular location to determine whether you can connect to it.

[Figure 18.3](#) shows the labels used by the Wi-Fi Alliance on 11Mbps, 54Mbps, and dual-band equipment along with the name of the official IEEE standard for each type of product.

Figure 18.3. The Wi-Fi Alliance's certification labels for Wi-Fi-compliant 802.11 hardware.

[\[View full size image\]](#)

IEEE 802.11b 11Mbps Wi-Fi

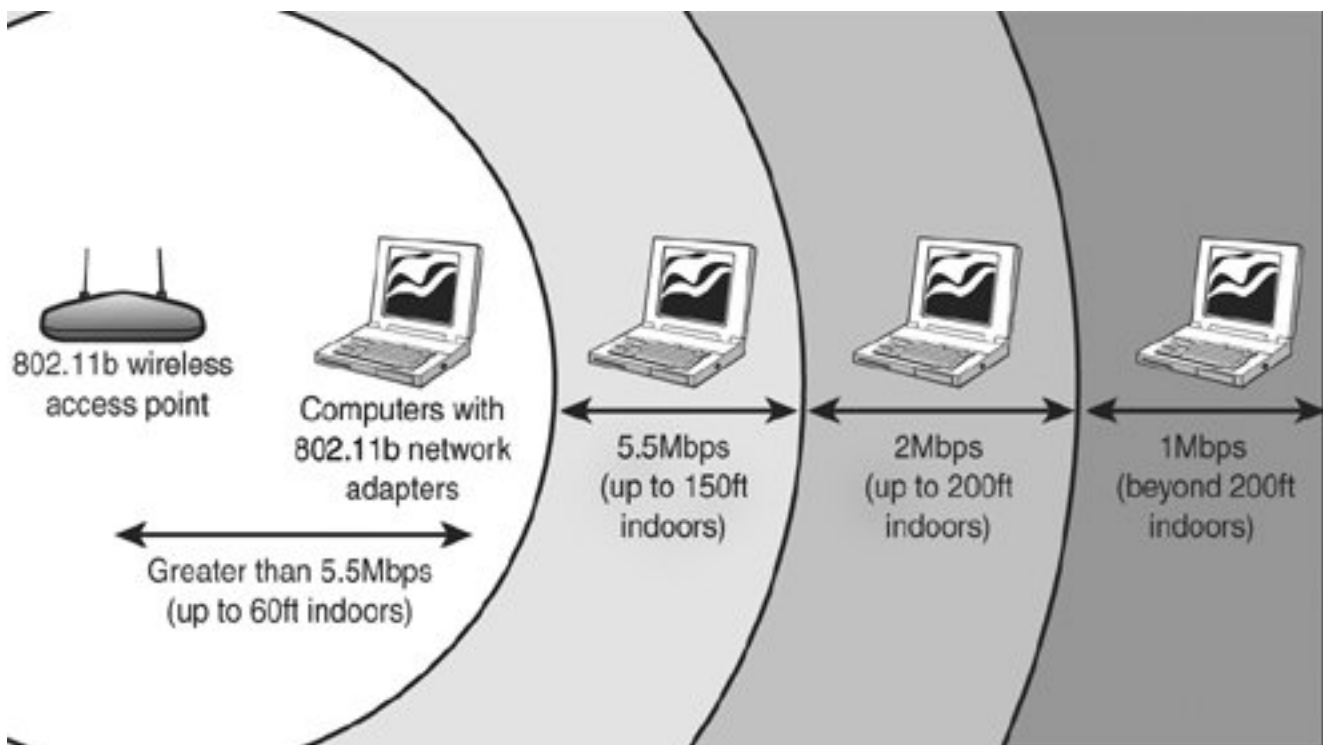

IEEE 802.11b (Wi-Fi 2.4GHz band-compliant) wireless networks run at a maximum speed of 11Mbps, about the same as 10BASE-T Ethernet (the original version of IEEE 802.11 supported data rates up to 2Mbps only). 802.11b networks can connect to conventional Ethernet networks or be used as independent networks, similar to other wireless networks. Wireless networks running 802.11b hardware use the same 2.4GHz spectrum that many portable phones, wireless speakers, security devices, microwave ovens, and the Bluetooth short-range networking products use. Although the increasing use of these products is a potential source of interference, the short range of wireless networks (indoor ranges up to approximately 150 feet and outdoor ranges up to about 300 feet, varying by product) minimizes the practical risks. Many devices use a spread-spectrum method of connecting with other products to minimize potential interference.

Although 802.11b supports a maximum speed of 11Mbps, that top speed is seldom reached in practice and speed varies by distance. Most 802.11b hardware is designed to run at four speeds, using one of four data-encoding methods, depending on the speed range:

- *11Mbps*. Uses quaternary phase-shift keying/complimentary code keying (QPSK/CCK)
- *5.5Mbps*. Also uses quaternary phase-shift keying/complimentary code keying (QPSK/CCK)
- *2Mbps*. Uses differential quaternary phase-shift keying (DQPSK)
- *1Mbps*. Uses differential binary phase-shift keying (DBPSK)

As distances change and signal strength increases or decreases, 802.11b hardware switches to the most suitable data-encoding method. The overhead required to track and change signaling methods, along with the additional overhead required when security features are enabled, helps explain why wireless hardware throughput is consistently lower than the rated speed. [Figure 18.4](#) is a simplified diagram showing how speed is reduced with distance. Figures given are for best-case situations; building design and antenna positioning can also reduce speed and signal strength, even at relatively short distances.

Figure 18.4. At short distances, 802.11b devices can connect at top speed (up to 11Mbps). However, as distance increases, speed decreases because the signal strength is reduced.

IEEE 802.11a Wi-Fi in the 5GHz Band

The second flavor of Wi-Fi is the wireless network known officially as IEEE 802.11a. 802.11a uses the 5GHz frequency band, which allows for much higher speeds (up to 54Mbps) and helps avoid interference from devices that cause interference with lower-frequency 802.11b networks. Although real-world 802.11a hardware seldom, if ever, reaches that speed (almost five times that of 802.11b), 802.11a maintains relatively high speeds at both short and long distances.

For example, in a typical office floor layout, the real-world throughput (always slower than the rated speed due to security and signaling overhead) of a typical 802.11b device at 100 feet might drop to about 5Mbps, whereas a typical 802.11a device at the same distance could have a throughput of around 15Mbps. At a distance of about 50 feet, 802.11a real-world throughput can be four times faster than 802.11b. 802.11a has a shorter maximum distance than 802.11b (approximately 75 feet indoors), but you get your data

much more quickly.

Given the difference in throughput (especially at long distances), and if we take the existence of 802.11g out of the equation for a moment, why not skip 802.11b altogether? In a single word: *frequency*. By using the 5GHz frequency instead of the 2.4GHz frequency used by 802.11b, standard 802.11a hardware cuts itself off from the already vast 802.11b universe, including the growing number of public and semipublic 802.11b wireless Internet connections (called *hot spots*) showing up in cafes, airports, hotels, and business campuses.

The current solution for maximum flexibility is to use dual-band hardware. As [Figure 18.3](#) demonstrated, the Wi-Fi Alliance is encouraging the manufacture of dual-band hardware through its certification program. Dual-band hardware can work with either 802.11a or 802.11b/g networks, enabling you to move from an 802.11b/g wireless network at home or at Starbucks to a faster 802.11a office network.

802.11 gA Compatible 54Mbps Standard

IEEE 802.11g, also known to some as *Wireless-G*, is a newer standard that combines compatibility with 802.11b with the speed of 802.11a at longer distances at a price only slightly higher than 802.11b hardware. The final 802.11g standard was ratified in mid-2003.

Although 802.11g promised to connect seamlessly with existing 802.11b hardware, early 802.11g hardware was slower and less compatible than the specification promised. In some cases, problems with early-release 802.11g hardware can be solved through firmware upgrades. 802.11g is currently the predominant wireless networking standard with 802.11b fading into the background.

Bluetooth

Bluetooth is a low-speed (up to 700Kbps), low-power standard originally designed to interconnect notebook computers, PDAs, cell phones, and pagers for data synchronization and user authentication in public areas, such as airports, hotels, rental car pickups, and sporting events. Bluetooth is also used for a wide variety of wireless devices on PCs, including printer adapters, keyboards and mice (Microsoft's Bluetooth keyboard and mouse are available at many stores selling computer hardware), DV camcorders, data projectors, and many others. A list of Bluetooth products and announcements is available at the official Bluetooth wireless information website: www.bluetooth.com. Bluetooth devices also use the same 2.4GHz frequency range Wi-Fi/IEEE 802.11b devices use. However, in an attempt to avoid interference with Wi-Fi, Bluetooth uses a signaling method called *frequency hopping spread spectrum (FHSS)*, which switches the exact frequency used during a Bluetooth session 1,600 times per second over the 79 channels Bluetooth uses. Unlike Wi-Fi, which is designed to allow a device to be part of a network at all times, Bluetooth is designed for ad hoc temporary networks in which two devices connect only long enough to transfer data and then break the connection.

Interference Issues Between Bluetooth and IEEE 802.11b/g

Despite the frequency-hopping nature of Bluetooth, studies have shown that Bluetooth (up through version 1.1) and IEEE 802.11b devices can interfere with each other, particularly at close range (under 2 meters) or when users attempt to use both types of wireless networking at the same time (as with an 802.11b wireless Internet connection on a computer with a Bluetooth wireless keyboard and mouse). Although 802.11g has not been specifically studied, it uses the same frequencies as 802.11b, and interference between 802.11g and Bluetooth can also take place under similar circumstances. Interference reduces throughput and in some circumstances can cause data loss.

An improved version of the Bluetooth specification (version 1.2) adds adaptive frequency hopping to solve interference problems when devices are more than 1 meter (3.3 feet) away from each other. However, close-range (less than 1 meter) interference can still take place.

IEEE has developed 802.15.2, a specification for enabling coexistence between 802.11b/g and Bluetooth. It can use various time-sharing or time-division methods to enable coexistence. However, these specifications are not yet part of typical 802.11b/g implementations.

Chipset makers Silicon Wave (www.siliconwave.com) and Intersil (www.intersil.com) have developed Blue802 Technology, a combination of chipsets that enables coexistence between Bluetooth and 802.11b wireless networks at any distance.

Hardware Elements of Your Network

The choice of a data-link protocol affects the network hardware you choose. Because Fast Ethernet, Gigabit Ethernet, Wireless Ethernet, and other data-link protocols use different hardware, you must select the architecture before you can select appropriate hardware, including network interface cards, cables, and hubs or switches.

Network Interface Cards

On most computers, the network interface adapter takes the form of a network interface card (NIC) that fits into a PCI slot on a desktop computer or a PC Card (PCMCIA) slot on a notebook computer. Although network cards for older systems might use the ISA or EISA slot standards, these don't support high-speed network standards and are obsolete. Many recent systemsboth workstations and serversincorporate the network interface adapter onto the motherboard.

Note

You can also adapt the USB port for Ethernet use with a USB-to-Ethernet adapter, but because USB 1.1 ports run at only 12Mbps (compared to Fast Ethernet running at 100Mbps), a performance bottleneck results. USB 2.0toFast Ethernet adapters are available from several vendors and are a suitable choice if your system has USB 2.0 ports but lacks a free PCI or PC Card slot.

Network adapters have unique hardware addresses coded into their firmware. The data link layer protocol uses these addresses to identify the other systems on the network. A packet gets to the correct destination because its data link layer protocol header contains the hardware addresses of both the sending and receiving systems.

Ethernet network adapters range in price from less than \$20 for client adapters to as much as \$100 or more for server-optimized adapters. Token-Ring adapters, if required, are much more expensive, ranging in price from around \$100 for client adapters to more than \$500 for server-optimized adapters. Network adapters are built in all the popular interface-card types and are also optimized for either workstation or server use. For first-time network users, so-called network-in-a-box kits are available that contain two 10/100 Fast Ethernet or Wireless NICs (or PC Cards), a small switch, and prebuilt UTP cables for less than \$100. When combined with the built-in networking software in Windows, these kits make networking very inexpensive. A number of 100/1000-BASE-TX Gigabit Ethernet adapters for use with UTP cable can be purchased for less than \$60, and many switches now also feature Gigabit Ethernet ports.

For client workstations (including peer servers on peer-to-peer networks), the following sections contain my recommendations on the features you need.

Speed

Your NIC should run at the maximum speed you want your network to support. For a Gigabit Ethernet network, for example, you should purchase Ethernet cards that support 1000BASE-T's 1000Mbps speed. Most Gigabit Ethernet and Fast Ethernet cards also support slower speeds, such as Fast Ethernet's 100Mbps

speed or standard Ethernet's 10Mbps speed, allowing the same card to be used on both older and newer portions of the network. To verify multispeed operation, look for network cards identified as 10/100 or 100/1000 Ethernet. In the case of wireless networking in the home, your best option remains 802.11g.

Your NIC should support both half-duplex and full-duplex operation:

- *Half-duplex* means that the network card can only send or only receive data in a single operation.
- *Full-duplex* means that the network card can both receive and send simultaneously. Full-duplex options boost network speed if switches are used in place of hubs. For example, 100Mbps Fast Ethernet cards running in full-duplex mode have a maximum true throughput of 200Mbps, with half going in each direction.

Unlike hubs, which broadcast data packets to all computers connected to it, switches create a direct connection between the sending and receiving computers. Thus, switches provide faster performance than hubs; most switches also support full-duplex operation, doubling the rated speed of the network when full-duplex network cards are used.

Bus Type

If you are networking desktop computers built from 1995 to the present, you should consider only PCI-based NICs (these computers typically have three or more PCI slots). Although many older computers still have at least one ISA or combo ISA/PCI expansion slot, the superior data bus width and data transfer rate of PCI make it the only logical choice for networks of all types. The integrated NIC found on most recent PC motherboards is also a PCI device. Alternative interfaces include USB or PC Card/Cardbus adapters that are often used for portable systems. At this time, there are also a handful of NICs based on PCI Express.

[Table 18.3](#) summarizes the differences between all the types of interfaces network cards use.

Table 18.3. Bus Choices for Client PC NICs

Bus Type	Bus Width (Bits)	Bus Speed (MHz)	Data Cycles per Clock	Bandwidth (MBps)
8-bit ISA (AT)	8	8.33	1/2	4.17
16-bit ISA (AT-Bus)	16	8.33	1/2	8.33
EISA Bus	32	8.33	1	33
MCA-16 Streaming	16	10	1	20
MCA-32 Streaming	32	10	1	40
MCA-64 Streaming	64	10	1	80
PC-Card (PCMCIA)	16	10	1	20
CardBus	32	33	1	133
PCI	32	33	1	133

PCI 66MHz	32	66	1	266
PCI 64-bit	64	33	1	266
PCI 66MHz/64-bit	64	66	1	533
USB 1.1	1	12	1	1.5
USB 2.0	1	480	1	60

Note: ISA, EISA, and MCA are no longer used in current motherboard designs.

MBps = Megabytes per second

ISA = Industry Standard Architecture, also known as the PC/XT (8-bit) or AT-Bus (16-bit)

EISA = Extended Industry Standard Architecture (32-bit ISA)

MCA = Microchannel Architecture (IBM PS/2 systems)

PC-Card = 16-bit PCMCIA (Personal Computer Memory Card International Association) interface

CardBus = 32-bit PC-Card

PCI = Peripheral Component Interconnect

USB = universal serial bus

Although a few ISA-based NICs are still on the market, their slow speeds and narrow bus widths severely restrict their performance. Most ISA-based Ethernet cards can't support speeds above 10Mbps and thus don't support Fast Ethernet or Gigabit Ethernet. A few vendors make 10/100 Ethernet cards for the ISA slot, but their performance is substantially lower than PCI cards. If you are shopping for a network card for a laptop or notebook system, look for Cardbus types, which are significantly faster than PC Cards and those using USB.

Wired Network Adapter Connectors

Wired Ethernet adapters typically have an RJ-45 connector, which looks like a large telephone jack. Fast Ethernet and Gigabit Ethernet twisted-pair cables use these connectors, but you might still find a few older adapters that support a single BNC connector (for Thinnet coaxial cables), or a D-shaped 15-pin connector called a DB15 (for Thicknet coaxial cables). A few older 10Mbps adapters have a combination of two or all three of these connector types; adapters with two or more connectors are referred to as *combo* adapters. Token-Ring adapters can have a 9-pin connector called a DB9 (for Type 1 STP cable) or sometimes an RJ-45 jack (for Type 3 UTP cable). [Figure 18.5](#) shows all three of the Ethernet connectors.

Figure 18.5. Three Ethernet connectors on two NICs: RJ-45 connector (top center), DB-15 connector (bottom right), and BNC connector (bottom left).

Virtually all 10/100 Ethernet NICs made for client-PC use on the market today are designed to support unshielded twisted-pair (UTP) cable exclusively; Gigabit Ethernet cards made for wired (not fiber-optic) networks also use only UTP cable. If you are adding a client PC to an existing network that uses some form of coaxial cable, you have four options:

- Purchase a combo NIC that supports coaxial cable as well as RJ-45 twisted-pair cabling.
- Purchase a media converter that can be attached to the coaxial cable to allow the newer UTP-based NICs to connect to the existing network.
- Use a switch or hub that has both coaxial cable and RJ-45 ports. A dual-speed (10/100) device is needed if you are adding one or more Fast Ethernet clients.
- Replace the coaxial installation with an updated Ethernet installation.

For maximum economy, NICs and network cables must match, although media converters can be used to interconnect networks based on the same standard, but using different cable.

Network Cables for Wired Ethernet

Originally, all networks used some type of cable to connect the computers on the network to each other. Although various types of wireless networks are now on the market, many office and home networks still use twisted-pair Ethernet cabling. Occasionally you might still find some based on Thick or Thin Ethernet coaxial cable.

Thick and Thin Ethernet Coaxial Cable

The first versions of Ethernet were based on coaxial cable. The original form of Ethernet, 10BASE-5, used a

thick coaxial cable (called Thicknet) that was not directly attached to the NIC. A device called an attachment unit interface (AUI) ran from a DB15 connector on the rear of the NIC to the cable. The cable had a hole drilled into it to allow the "vampire tap" to be connected to the cable. NICs designed for use with thick Ethernet cable are almost impossible to find as new hardware today.

10BASE-2 Ethernet cards use a BNC (Bayonet-Neill-Concilman) connector on the rear of the NIC. Although the thin coaxial cable (called Thinnet or RG-58) used with 10BASE-2 Ethernet has a bayonet connector that can physically attach to the BNC connector on the card, this configuration is incorrect and won't work. Instead, a BNC T-connector attaches to the rear of the card, allowing a thin Ethernet cable to be connected to either both ends of the T (for a computer in the middle of the network) or to one end only (for a computer at the end of the network). A 50-ohm terminator is connected to the other arm of the T to indicate the end of the network and prevent erroneous signals from being sent to other clients on the network. Some early Ethernet cards were designed to handle thick (AUI/DB15), thin (RG-58), and UTP (RJ-45) cables. Combo cards with both BNC and RJ-45 connectors may still be available but can run at only standard Ethernet speeds.

[Figure 18.6](#) compares Ethernet DB-15 to AUI, BNC coaxial T-connector, and RJ-45 UTP connectors to each other, and [Figure 18.7](#) illustrates the design of coaxial cable.

Figure 18.6. An Ethernet network card with thick Ethernet (DB-15), thin Ethernet (RG-58 with T-connector), and UTP (RJ-45) connectors.

Figure 18.7. Coaxial cable.

Twisted-Pair Cable

Twisted-pair cable is just what its name implies: insulated wires within a protective casing with a specified number of twists per foot. Twisting the wires reduces the effect of electromagnetic interference (that can be generated by nearby cables, electric motors, and fluorescent lighting) on the signals being transmitted. Shielded twisted pair (STP) refers to the amount of insulation around the cluster of wires and therefore its immunity to noise. You are probably familiar with unshielded twisted-pair (UTP) cable; it is often used for telephone wiring. [Figure 18.8](#) shows unshielded twisted-pair cable; [Figure 18.9](#) illustrates shielded twisted-pair cable.

Figure 18.8. An unshielded twisted-pair (UTP) cable.

Figure 18.9. A shielded twisted-pair (STP) cable.

Shielded Versus Unshielded Twisted Pair

When cabling was being developed for use with computers, it was first thought that shielding the cable from external interference was the best way to reduce interference and provide for greater transmission speeds. However, it was discovered that twisting the pairs of wires is a more effective way to prevent interference from disrupting transmissions. As a result, earlier cabling scenarios relied on shielded cables rather than the unshielded cables more commonly in use today.

Shielded cables also have some special grounding concerns because one, and only one, end of a shielded cable should be connected to an earth ground; issues arose when people inadvertently caused grounding loops to occur by connecting both ends or caused the shield to act as an antenna because it wasn't grounded.

Grounding loops are situations in which two different grounds are tied together. This is a bad situation because each ground can have a slightly different potential, resulting in a circuit that has very low voltage but infinite amperage. This causes undue stress on electrical components and can be a fire hazard.

Most Ethernet and Fast Ethernet installations that use twisted-pair cabling use UTP because the physical flexibility and small size of the cable and connectors makes routing it very easy. However, its lack of electrical insulation can make interference from fluorescent lighting, elevators, and alarm systems (among other devices) a major problem. If you use UTP in installations where interference can be a problem, you need to route the cable away from the interference, use an external shield, or substitute STP for UTP near interference sources.

Four standard types of unshielded twisted-pair cabling exist and are still used to varying degrees:

- *Category 3 cable.* The original type of UTP cable used for Ethernet networks was also the same as that used for business telephone wiring. This is known as Category 3, or voice-grade UTP cable, and is measured according to a scale that quantifies the cable's data-transmission capabilities. The cable itself is 24 AWG (American Wire Gauge, a standard for measuring the diameter of a wire), copper-

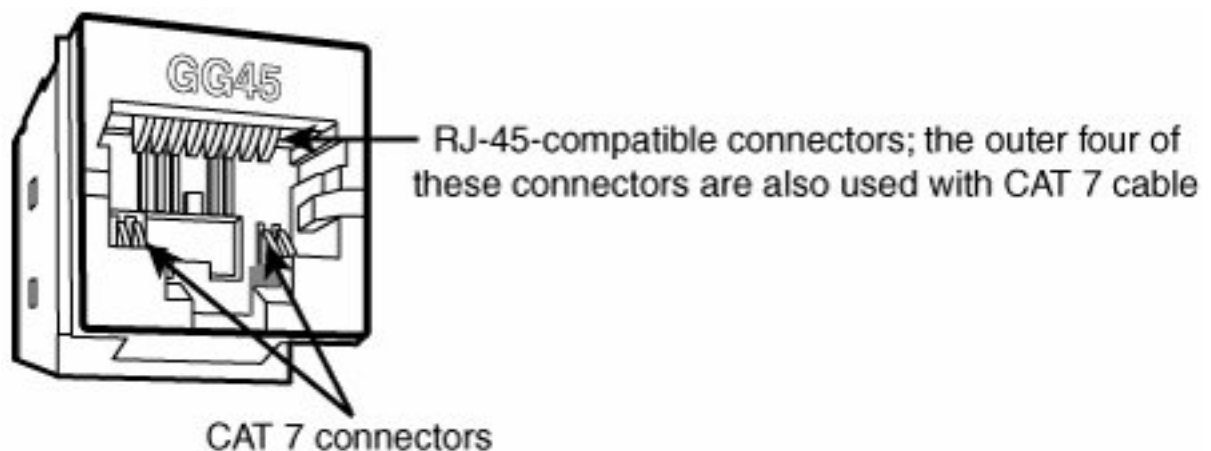

tinned with solid conductors, 100105 ohm characteristic impedance, and a minimum of two twists per foot. Category 3 cable is largely obsolete because it is only adequate for networks running at up to 16Mbps so it cannot be used with Fast or Gigabit Ethernet.

- *Category 5 cable.* The newer, faster network types require greater performance levels. Fast Ethernet (100BASE-TX) uses the same two-wire pairs as 10BASE-T, but Fast Ethernet needs a greater resistance to signal crosstalk and attenuation. Therefore, the use of Category 5 UTP cabling is essential with 100BASE-TX Fast Ethernet. Although the 100BASE-T4 version of Fast Ethernet can use all four-wire pairs of Category 3 cable, this flavor of Fast Ethernet is not widely supported and has practically vanished from the marketplace. If you try to run Fast Ethernet 100BASE-TX over Category 3 cable, you will have a slow and unreliable network. Category 5 cable is commonly called CAT5 and is also referred to as Class D cable.

Many cable vendors also sell an enhanced form of Category 5 cable called Category 5e (specified by Addendum 5 of the ANSI/TIA/EIA-568-A cabling standard). Category 5e cable can be used in place of Category 5 cable and is especially well suited for use in Fast Ethernet networks that might be upgraded to Gigabit Ethernet in the future. Category 5e cabling must pass several tests not required for Category 5 cabling. Even though you can use both Category 5 and Category 5e cabling on a Gigabit Ethernet (1000BASE-TX) network, Category 5e cabling provides better transmission rates and a greater margin of safety for reliable data transmission.

- *Category 6 cable.* Category 6 cabling (also called CAT 6 or Class E) can be used in place of CAT 5 or 5e cabling and uses the same RJ-45 connectors as CAT 5 and 5e. CAT 6 cable handles a frequency range of 1MHz250MHz, compared to CAT5 and CAT5e's 1MHz100MHz frequency range.
- *Category 7 cable.* Category 7 (also called CAT 7 or Class F) is the newest cabling standard and handles a frequency range of 1MHz600MHz, which reduces propagation delay and delay skew. This enables longer network cables and larger numbers of workstations on a network. CAT 7 uses the GG45 connector developed by Nexans. This connector resembles the RJ-45 connector but has four additional contacts (see [Figure 18.10](#)). The GG45 connector contains a switch that activates a maximum of 8 out of 12 contacts. The upper 8 RJ-45 contacts are used for up to 250MHz (CAT 6) operation, whereas the 8 contacts in the outer edges are used for 600MHz (CAT 7) operation. Only 8 contacts are used at a given time. In other words, this connector is designed to be backward compatible with cables using RJ-45 connectors while supporting the newer standard.

Figure 18.10. The GG45 connector from Nexans can accept CAT 5 and other standard network cabling using the RJ-45 connector or the new CAT 7 cabling.

Caution

If you choose to install Category 5/5e UTP cable, be sure that all the connectors, wall plates,

and other hardware components involved are also Category 5 rated.

If you are trying to connect prebuilt Category 5 cabling together on a Fast Ethernet network, use Category 5 grade or better connectors; otherwise, you'll create a substandard section that might fail in your network.

Choosing the correct type of Category 5/5e/6/7 cable is also important. Use solid PVC cable for network cables that represent a permanent installation. However, the slightly more expensive stranded cables are a better choice for a notebook computer or temporary wiring of no more than 10-foot lengths (from a computer to a wall socket, for example) because it is more flexible and is therefore capable of withstanding frequent movement.

If you plan to use air ducts or suspended ceilings for cable runs, you should use Plenum cable, which doesn't emit harmful fumes in a fire. It is much more expensive, but the safety issue is a worthwhile reason to use it (some localities require you to use Plenum cabling).

Building Your Own Twisted-Pair Cables

When it's time to wire your network, you have two choices. You can opt to purchase prebuilt cables, or you can build your own cables from bulk wire and connectors.

You should build your own twisted-pair cables if you

- Plan to perform a lot of networking
- Need cable lengths longer than the lengths you can buy preassembled at typical computer departments
- Want to create both standard and crossover cables
- Want to choose your own cable color
- Want maximum control over cable length
- Want to save money
- Have the time necessary to build cables

Twisted Pair Wiring Standards

If you want to create twisted-pair (TP) cables yourself, be sure your cable pairs match the color-coding of any existing cable or the color-coding of any prebuilt cabling you want to add to your new network. Because there are eight wires in TP cables, many incorrect combinations are possible. Several standards exist for UTP cabling.

Tip

The keys are to be consistent, use the same scheme for all your cables, and ensure that anyone else working on your network understands the scheme used in it.

One common standard is the AT&T 258A configuration (also called EIA/TIA 568B). [Table 18.4](#) lists the wire

pairing and placement within the standard RJ-45 connector.

Table 18.4. RJ-45 Connector Wire Pairing and Placement for AT&T 258A/EIA 568B Standard

Wire Pairing	Wire Connected to Pin #	Pair Used for
White/blue and blue	White/blue - #5 Blue - #4	Not used ^[*]
White/orange and orange	White/orange - #1 Orange - #2	Transmit
White/green and green	White/green - #3 Green - #6	Receive
White/brown and brown	White/brown - #7 Brown - #8	Not used ^[*]

^[*] This pair is not used with 10BASE-T or Fast Ethernet 100BASE-TX, but all four pairs are used with Fast Ethernet 100BASE-T4 and Gigabit Ethernet 1000BASE-TX standards.

In [Figure 18.11](#) an RJ-45 cable connector is wired to the AT&T 258A/EIA 568B standard.

Figure 18.11. An AT&T 258A/EIA 568B standard compliant RJ-45 connector.

Note

You also might encounter the similar EIA 568A standard. It reverses the position of the orange and green pairs listed previously.

Crossover UTP Cables

Crossover cables, which change the wiring at one end of the cable, are used to connect two (and only two) computers when no hub or switch is available or to connect a hub or switch without an uplink port to another hub or switch. The pinout for a crossover cable is shown in [Table 18.5](#). This pinout is for one end of the cable only; the other end of the cable should correspond to the standard EIA 568B pinout, as shown previously in [Figure 18.11](#).

Table 18.5. RJ-45 Connector Wire Pairing and Placement for Crossover Variation on EIA 568B Standard

Wire	Pin #	Wire	Pin #
White/blue	5	White/orange	3
Blue	4	Orange	6
White/green	1	White/brown	7
Green	2	Brown	8

Note

It should be noted that other wiring schemes exist, such as IEEE and USOC. All told, at least eight agreed-on standards exist for connecting UTP cables and RJ-45 connectors. The ones listed in this chapter are the most common.

Constructing the Cable

Making your own UTP cables requires a few tools that aren't commonly found in a typical toolbox. Those items that you might not already have you can typically purchase for a single price from many network-products vendors. You will need the following tools and supplies to build your own Ethernet cables:

- UTP cable (Category 5 or better)

- RJ-45 connectors
- Wire stripper
- RJ-45 crimping tool

Before you make a "real" cable of any length, you should practice on a short length of cable. RJ-45 connectors and bulk cable are cheap; network failures are not. Follow these steps for creating your own twisted-pair cables:

1.

Determine how long your UTP cable should be. You should allow adequate slack for moving the computer and for avoiding strong interference sources. Keep the maximum distances for UTP cables of about 100 meters in mind.

2.

Roll out the appropriate length of cable.

3.

Cut the cable cleanly from the box of wire.

4.

Use the wire stripper to strip only the insulation jacket off the cable, exposing the TP wires (see [Figure 18.12](#)); you'll need to rotate the wire about 1 1/4 turns to strip away all the jacket. If you turn it too far, you'll damage the wires inside the cable.

Figure 18.12. Carefully strip the cable jacket away to expose the four wire pairs.

5.

Check the outer jacket and inner TP wires for nicks; adjust the stripper tool and repeat steps 3 and 4 if you see damage.

6.

As shown in [Figure 18.13](#), arrange the wires according to the EIA 568B standard. This arrangement is listed previously, in the section "[Twisted Pair Wiring Standards](#)."

Figure 18.13. Arrange the wire pairs for insertion into the RJ-45 connector according to your chosen scheme (EIA 568B, for instance).

7.

Trim the wire edges so the eight wires are even with one another and are slightly less than 1/2" past the end of the jacket. If the wires are too long, crosstalk (wire-to-wire interference) can result; if the wires are too short, they can't make a good connection with the RJ-45 plug.

8.

With the clip side of the RJ-45 plug facing away from you, push the cable into place (see [Figure 18.14](#)). Verify that the wires are arranged according to the EIA/TIA 568B standard *before* you crimp the plug onto the wires (refer to [Table 18.4](#) and [Figure 18.11](#) earlier in this chapter). Adjust the connection as necessary.

Figure 18.14. Push the RJ-45 connector into place, ensuring the cable pairs are ordered properly.

9.

Use the crimping tool to squeeze the RJ-45 plug onto the cable (see [Figure 18.15](#)). The end of the cable should be tight enough to resist being removed by hand.

Figure 18.15. Firmly squeeze the crimping tool to attach the connector to the cable.

10.

Repeat steps 49 for the other end of the cable. Recut the end of the cable if necessary before stripping it.

11.

Label each cable with the following information:

- Wiring standard
- Length
- End with crossover (if any)
- _____ (a blank) for computer ID

The cables should be labeled at both ends to make matching the cable with the correct computer easy and to facilitate troubleshooting at the hub. Check with your cable supplier for suitable labeling stock or tags you can attach to each cable.

Cable Distance Limitations

The people who design computer systems love to find ways to circumvent limitations. Manufacturers of Ethernet products have made possible the building of networks in star, branch, and tree designs that overcome the basic limitations already mentioned (for more information, see the "[Network Topologies](#)" section later in this chapter). Strictly speaking, you can have thousands of computers on a complex Ethernet network.

LANs are local because the network adapters and other hardware components typically can't send LAN messages more than a few hundred feet. [Table 18.6](#) lists the distance limitations of various types of LAN cable. In addition to the limitations shown in the table, keep the following points in mind:

- You can't connect more than 30 computers on a single Thinnet Ethernet segment.
- You can't connect more than 100 computers on a Thicknet Ethernet segment.
- You can't connect more than 72 computers on a UTP Token-Ring cable.
- You can't connect more than 260 computers on an STP Token-Ring cable.

If you have a station wired with Category 5 cable that is more than 328 feet (100 meters) from a hub, you must use a repeater. If you have two or more stations beyond the 328 feet limit of UTP Ethernet, connect them to a hub or switch that is less than 328 feet away from the primary hub or switch and connect the new hub or switch to the primary hub or switch via its uplink port. Because hubs and switches can act as repeaters, this feature enables you to extend the effective length of your network (see [Figure 18.16](#)).

Table 18.6. Network Distance Limitations

Network Adapter	Cable Type	Maximum	Minimum
Ethernet	10BASE-2	185m (607 ft.)	0.5m (1.6 ft.)
	10BASE-5 (drop)	50m (164 ft.)	2.5m (8.2 ft.)
	10BASE-5 (backbone)	500m (1,640 ft.)	2.5m (8.2 ft.)
	10BASE-T	100m (328 ft.)	2.5m (8.2 ft.)
	100BASE-TX	100m (328 ft.)	2.5m (8.2 ft.)
	1000BASE-TX	100m (328 ft.)	
Token-Ring	STP	100m (328 ft.)	2.5m (8.2 ft.)
	UTP	45m (147 ft.)	2.5m (8.2 ft.)
ARCnet	Passive hub drop	30m (98 ft.)	Varies by cable type Varies by cable type
	Active hub	600m (1,968 ft.)	

Figure 18.16. In case A (top), the workstations on the right are too far away from the hub to connect to a Fast Ethernet network. In case B (bottom), an additional hub or switch is used to allow the workstations to be added to the network.

Network Topologies

Each computer on the network is connected to the other computers with cable (or some other medium, such as wireless using radio frequency signals). The physical arrangement of the cables connecting computers on a network is called the network *topology*.

Over the last 15 years the three types of basic topologies used in computer networks have been as follows:

- *Bus*. Connects each computer on a network directly to the next computer in a linear fashion. The network connection starts at the server and ends at the last computer in the network. (Obsolete.)
- *Star*. Connects each computer on the network to a central access point.
- *Ring*. Connects each computer to the others in a loop or ring. (Obsolete.)

For a long while, these different topologies were often mixed, forming what is called a *hybrid network*. For example, you can link the hubs of several star networks together with a bus, forming a star-bus network. Rings can be connected in the same way.

[Table 18.7](#) summarizes the relationships between network types and topologies.

Table 18.7. Network Cable Types and Topologies

Network Type	Standard	Cable Type	Topology
Ethernet	10BASE-2	Thin (RG-58) coaxial	Bus
Ethernet	10BASE-5	Thick coaxial	Bus
Ethernet	10BASE-T	Cat 3 or Cat 5 UTP	Star
Fast Ethernet	100BASE-TX	Cat 5 UTP	Star
Gigabit Ethernet	1000BASE-TX	Cat 5, 5e, or 6 UTP	Star
Token-Ring	(all)	UTP or STP	Logical ring

The bus, star, and ring topologies are discussed in the following sections. Wireless networking, which technically doesn't have a physical topology as described here, does still employ two logical (virtual) topologies, which I discuss here as well.

Bus Topology

The earliest type of network topology was the *bus topology*, which uses a single cable to connect all the computers in the network to each other, as shown in [Figure 18.17](#). This network topology was adopted initially because running a single cable past all the computers in the network is easier and less wiring is used than with other topologies. Because early bus topology networks used bulky coaxial cables, these factors were important advantages. Both 10BASE-5 (thick) and 10BASE-2 (thin) Ethernet networks are based on the bus topology.

Figure 18.17. A 10BASE-2 network is an example of a linear bus topology, attaching all network devices to a common cable.

However, the advent of cheaper and more compact unshielded twisted-pair cabling, which also supports faster networks, has made the disadvantages of a bus topology apparent. If one computer or cable connection malfunctions, it can cause all the stations beyond it on the bus to lose their network connections. Thick Ethernet (10BASE-5) networks often fail because the vampire tap connecting the AUI device to the coaxial cable comes loose. In addition, the T-adapters and terminating resistors on a 10BASE-2 Thin Ethernet network can also come loose or be removed by the user, causing all or part of the network to fail. Another drawback of Thin Ethernet (10BASE-2) networks is that adding a new computer to the network between existing computers might require replacement of the existing network cable between the computers with shorter segments to connect to the new computer's network card and T-adapter, thus creating downtime for users on that segment of the network.

Ring Topology

Another topology often listed in discussions of this type is a *ring*, in which each workstation is connected to the next and the last workstation is connected to the first again (essentially a bus topology with the two ends connected). Two major network types use the ring topology:

- *Fiber Distributed Data Interface (FDDI)*. A network topology used for large, high-speed networks using fiber-optic cables in a physical ring topology
- *Token-Ring*. Uses a logical ring topology

A Token-Ring network resembles a 10BASE-T or 10/100 Ethernet network at first glance because both networks use a central connecting device and a physical star topology. Where is the "Ring" in Token-Ring?

The ring exists only within the device that connects the computers, which is called a *multistation access unit (MSAU)* on a Token-Ring network (see [Figure 18.18](#)).

Figure 18.18. A Token-Ring network during the sending of data from one computer to another.

Signals generated from one computer travel to the MSAU, are sent out to the next computer, and then go back to the MSAU again. The data is then passed to each system in turn until it arrives back at the computer that originated it, where it is removed from the network. Therefore, although the physical wiring topology is a star, the data path is theoretically a ring. This is called a *logical ring*.

A logical ring that Token-Ring networks use is preferable to a physical ring network topology because it affords a greater degree of fault tolerance. As on a bus network, a cable break anywhere in a physical ring network topology, such as FDDI, affects the entire network. FDDI networks use two physical rings to provide a backup in case one ring fails. By contrast, on a Token-Ring network, the MSAU can effectively remove a malfunctioning computer from the logical ring, enabling the rest of the network to function normally.

Star Topology

By far the most popular type of topology in use today has separate cables to connect each computer to a central wiring nexus, often called a *switch* or *hub*. [Figure 18.19](#) shows this arrangement, which is called a *star topology*.

Figure 18.19. The star topology, linking the LAN's computers and devices to one or more central hubs, or access units.

Because each computer uses a separate cable, the failure of a network connection affects only the single machine involved. The other computers can continue to function normally. Bus cabling schemes use less cable than the star but are harder to diagnose or bypass when problems occur. At this time, Fast Ethernet in a star topology is the most commonly implemented type of LAN; this is the type of network you build with most preconfigured wired networking kits. 10BASE-T Ethernet and 1000BASE-TX Gigabit Ethernet also use the star topology.

Wireless Network Logical Topologies

Wireless networks have different topologies, just as wired networks do. However, wireless networks use only two logical topologies:

- *Star*. The star topology, used by Wi-Fi/IEEE 802.11based products in the infrastructure mode, resembles the topology used by 10BASE-T and faster versions of Ethernet that use a switch. The access point takes the place of the switch because stations connect via the access point, rather than directly with each other. This method is much more expensive per unit but permits performance in excess of 10BASE-T Ethernet speeds and has the added bonus of being easier to manage.
- *Point-to-Point*. Bluetooth products (as well as Wi-Fi products in the *ad hoc* mode) use the point-to-point topology. These devices connect directly with each other and require no access point or other hub-like device to communicate with each other, although shared Internet access does require that all computers connect to a common wireless gateway. The point-to-point topology is much less expensive per unit than a star topology. It is, however, best suited for temporary data sharing with another device (Bluetooth) and is currently much slower than 100BASE-TX networks.

[Figure 18.20](#) shows a comparison of wireless networks using these two topologies.

Figure 18.20. A logical star topology (left) as used by IEEE 802.11based wireless Ethernet in infrastructure mode compared to a point-to-point topology as used by Bluetooth and 802.11 in ad hoc mode (right).

Hubs and Switches for Ethernet Networks

As you have seen, modern Ethernet workgroup networks—whether wireless or wired with UTP cable—are usually arranged in a star topology. The center of the star uses a multiport connecting device that can be either a hub or a switch. Although hubs and switches can be used to connect the network and can have several features in common, the differences between them are also significant and are covered in the following sections.

All Ethernet hubs and switches have the following features:

- Multiple RJ-45 UTP connectors (wireless switches still include wired ports)
- Diagnostic and activity lights
- A power supply

Ethernet hubs and switches are made in two forms: managed and unmanaged. *Managed* hubs and switches can be directly configured, enabled or disabled, or monitored by a network operator and are commonly used on corporate networks. Workgroup and home-office networks use less expensive *unmanaged* hubs, which simply connect computers on the network using the systems connected to it to provide a management interface for its configurable features.

Note

The now-obsolete ARCnet network used its own types of hubs: passive hubs, which were unpowered, and active hubs, which used a power supply. Neither type of hub is compatible with Ethernet.

Signal lights on the front of the hub or switch indicate which connections are in use by computers; switches also indicate whether a full-duplex connection is in use. Multispeed hubs and switches also indicate which connection speed is in use on each port. Your hub or switch must have at least one RJ-45 UTP connector for each computer you want to connect to it.

How Hubs Work

A computer on an Ethernet network broadcasts (sends) a request for network information or programs from a specific computer through the cable to the hub, which broadcasts the request to all computers connected to it. When the destination computer receives the message, it sends the requested information back to the hub, which broadcasts it again to all computers, although only the requesting computer acts on the information. Thus, a hub acts similarly to a radio transmitter and receiver that sends a signal to all radios, but only the radios set for the correct station can send or receive the information. Switches, due to the features explained in the next section, have largely replaced hubs on retail store shelves.

How Switches Differ from Hubs

Switches, as shown in [Figure 18.21](#), are similar to hubs in both form factor and function. As with hubs, they connect computers on an Ethernet network to each other. However, instead of broadcasting data to all computers on the network as hubs do, switches use a feature called *address storing*, which checks the destination for each data packet and sends it directly to the computer for which it's intended. Thus, a switch can be compared to a telephone exchange, making direct connections between the originator of a call and the receiver.

Figure 18.21. Front (top) and rear (bottom) of a typical five-port, 10/100 Ethernet switch.

Because switches establish a direct connection between the originating and receiving PC, they also provide the full bandwidth of the network to each port. Hubs, by contrast, must subdivide the network's bandwidth by the number of active connections on the network, meaning that bandwidth rises and falls depending on network activity.

For example, assume you have a four-station network workgroup using 10/100 NICs and a Fast Ethernet hub. The total bandwidth of the network is 100Mbps. However, if two stations are active, the effective bandwidth available to each station drops to 50Mbps (100Mbps divided by 2). If all four stations are active, the effective bandwidth drops to just 25Mbps (100Mbps divided by 4)! Add more active users, and the effective bandwidth continues to drop.

By replacing the hub with a switch, the effective bandwidth for each station remains 100Mbps because the switch doesn't broadcast data to all stations.

Most 10/100 NICs and Fast Ethernet or 10/100 switches also support full-duplex (simultaneous transmit and receive), enabling actual bandwidth to be double the nominal 100Mbps rating: 200Mbps. [Table 18.8](#) summarizes the differences between the two devices.

Table 18.8. Ethernet Hub and Switch Comparison

Feature	Hub	Switch
Bandwidth	Divided by total number of ports in use	Dedicated to each port in use
Data transmission	Broadcast to all connected computers	Broadcast only to the receiving computer
Duplex support	Half-duplex	Full-duplex when used with full-duplex NICs

As you can see, using a switch instead of a hub greatly increases the effective speed of a network, even if all other components remain the same.

Because of the improved performance of switches, I recommend them instead of hubs for networks of any size. When it comes time to purchase a hub or switch, you'll often find that the price difference is negligible between the two, so the switch makes good economic sense as well.

Additional Hub and Switch Features You Might Need

Although older hubs and switches run at only a single speed and have only a few RJ-45 connectors, it makes sense to upgrade to newer, more flexible equipment. Most recent hubs and switches have the following useful features, which are worth asking for:

- *Multispeed hubs/switches.* If you are adding Gigabit Ethernet (1000BASE-TX) or Fast Ethernet (100BASE-TX) clients to an existing 10BASE-T network, you need a multispeed hub or switch to connect the various types of Ethernet together.

Even if you are building a brand-new Gigabit Ethernet or Fast Ethernet network, a multispeed hub or switch is useful for occasionally hosting a "guest" PC that has only a slower-speed NIC onboard. Even though most Gigabit Ethernet and Fast Ethernet switches and hubs on the market today are actually 10/100/1000 or 10/100 multispeed models, you might still encounter a single-speed only unit. These single-speed units should be used only on networks that will never have a need to support a slower connection.

- *Wireless access point.* Many switches today also feature a built-in wireless access point that supports 802.11b/g or 802.11a (dual-mode access points support all three). If you plan to implement a wireless network in the future, getting a switch with a wireless access point built in now is worth the minimal increase in cost.
- *Stackable hub or switch with an uplink port.* A *stackable* hub or switch is one that can be connected to another hub or switch (and often stacked on top of it), enabling you to add computers to your network without replacing the hub or switch every time it runs out of connections. Most hubs and switches on the market today are stackable (but very small) hubs, and some older models might lack this feature. You can use this feature to add 10/100/1000 features to an older 10BASE-T-only network and connect a multispeed hub or switch to the uplink port on your 10BASE-T hub.
- *"Extra" ports beyond your current requirements.* If you are connecting four computers together into a small network, you need a four-port hub or switch (the smallest available). But, if you buy a hub or switch with only four ports and want to add another client PC to the network, you must add a second hub or switch or replace the hub or switch with a larger one with more ports.

Instead, plan for the future by buying a hub or switch that can handle your projected network growth over the next year. If you plan to add two workstations, buy at least an eight-port hub or switch (the cost per connection drops as you buy hubs and switches with more connections). Even though most hubs and switches are stackable to support the growth of your network, the more

ports a hub or switch has, the less expensive per port it will be.

To determine whether a hub or switch is stackable, look for an uplink port. This port looks like an ordinary RJ-45 UTP port, but it is wired differently, enabling you to use a standard-pinout RJ-45 UTP cable to connect it to another hub. Without the uplink port, you'd have to use a specially wired crossover cable.

Note

The uplink port on your hub or switch is also used to connect the hub or switch to a router or gateway device that provides an Internet connection for your network. In cases where multiple hubs or switches are to be used, they are usually connected directly to the router or gateway instead of chained (or stacked) off each other.

Typically, hubs and switches with an uplink port allow you to use the port along with all but one of the normal ports on the hub. For example, one of my associates uses a five-port switch from Linksys that also contains a router (for Internet access) and an uplink port. If his office network expands beyond five computers, he can use the uplink port to add another switch to expand the network and provide the new stations, as well as the original network, with Internet access.

Hub and Switch Placement

Although large networks have a wiring closet near the server, the workgroup-size LANs found in a small office or home office network obviously don't require anything of the sort. However, the location of the hub or switch is important, even if your LAN is based solely on a Wi-Fi architecture.

Ethernet hubs and switches require electrical power, whether they are small units that use a power "brick" or larger units that have an internal power supply and a standard three-prong AC cord.

In addition to electrical power, consider placing the hub or switch where its signal lights will be easy to view for diagnostic purposes and where its RJ-45 connectors can be reached easily. This is important both when it's time to add another user or two and when you need to perform initial setup of the switch (requiring a wired connection) or need to troubleshoot a failed wireless connection. In many offices, the hub or switch sits on the corner of the desk, enabling the user to see network problems just by looking at the hub or switch.

If the hub or switch also integrates a router for use with a broadband Internet device, such as a DSL or cable modem, you can place it near the cable or DSL modem or at a distance if the layout of your home or office requires it. Because the cable or DSL modem usually connects to your computer by the same Category 5 cable used for UTP Ethernet networking, you can run the cable from the cable or DSL modem to the router/switch's WAN port and connect all the computers to the LAN ports on the router/switch.

Except for the 328-ft. (100-meter) limit for all forms of UTP Ethernet (10BASE-T, 100BASE-TX, and 1000BASE-TX), distances between each computer on the network and the hub or switch aren't critical, so put the hub or switch wherever you can supply power and gain easy access.

Although wireless networks do offer more freedom in terms of placing the switch/access point, you should keep in mind the distances involved (generally up to 150 feet indoor for 802.11b/g) and any walls or devices using the same 2.4GHz spectrum that might interfere with the signal.

Tip

Decide where you plan to put your hub or switch before you buy prebuilt UTP wiring or make your own; if you move the hub or switch, some of your wiring will no longer be the correct length. Although excess lengths of UTP cable can be coiled and secured with cable ties, cables that are too short should be replaced. You can buy RJ-45 connectors to create one long cable from two short cables, but you must ensure the connectors are Category 5 if you are running Fast Ethernet; some vendors still sell Category 3 connectors that support only 10Mbps. You're really better off replacing the too-short cable with one of the correct length.

More on Wireless Ethernet Hardware

All types of 802.11 wireless networks have two basic components:

- Access points
- NICs equipped with radio transceivers

An *access point* is a bookend-size device that uses one or more RJ-45 ports to attach to a 10BASE-T or 10/100 Ethernet network (if desired) and contains a radio transceiver, encryption, and communications software. It translates conventional Ethernet signals into wireless Ethernet signals that it broadcasts to wireless NICs on the network and then performs the same role in reverse to transfer signals from wireless NICs to the conventional Ethernet network.

For coverage of a large area, purchase two or more access points and connect them to an Ethernet switch or hub. This enables users to roam inside a building without losing contact with the network. Some access points can communicate directly with each other via radio waves, enabling you to create a wireless backbone that can cover a wide area (such as a warehouse) without the need to run any network cabling. You can also purchase a wireless Ethernet range extender that can receive and boost weak Wi-Fi signals.

Access points are not necessary for direct peer-to-peer networking (also called *ad hoc mode*), but they are required for a shared Internet connection or a connection with another network. When access points are used, the network is operating in the *infrastructure mode*.

NICs equipped for wireless Ethernet communications have a fixed or detachable radio antenna. Because a major market for wireless Ethernet use is notebook computer users, a few vendors sell only PC Cards in their wireless Ethernet product lines, but most vendors support PCI cards for desktop computers. Most vendors also offer wireless USB adapters for use in both desktop and notebook computers. Because you can mix and match Wi-Fi-certified products that use the same frequency band, you can incorporate any mix of desktop and notebook computers into your wireless network. [Figure 18.22](#) illustrates typical wireless network hardware.

Figure 18.22. A typical family of Wi-Fi 2.4GHz band (802.11b) wireless products, including a wireless access point, USB, PC Card, and PCI wireless network adapters. The PC Card is used in notebook computers that lack Wi-Fi support and acts as the transceiver for the PCI card used in desktop computers. Photos courtesy of Linksys.

In cases where a Wi-Fi-enabled system receives multiple Wi-Fi signals, client systems lock onto the strongest signal from access points and automatically roam (switch) to another access point when the signal strength is stronger and the error level is lower than the current connection. Of course, if you want the system to lock onto a specific signal, that can be done via the OS or manufacturer-provided software.

Additional hardware you might need to add to your network includes

- *Wireless bridges.* These devices enable you to connect a wired Ethernet device, including non-computer items such as video games or set-top boxes, to a wireless network.
- *Wireless repeaters/range extenders.* A repeater can be used to stretch the range of an existing wireless network. Some can also be used as access points or wireless bridges.
- *Wireless router.* Use this in place of a standard access point to enable a wireless network to connect to the Internet through a cable modem or other broadband device (refer to [Chapter 17](#), "Internet Connectivity," for details). For additional flexibility, many wireless routers also include a multiport switch for use with wired Ethernet networks, and some also include a print server.
- *Specialized antennas.* The "rabbit ears" antennas used by most access points and routers are adequate for short distances, but longer distances or problems with line-of-sight reception can be solved by attaching specialized ceiling, wall, omnidirectional, or directional antennas in place of the standard antenna.
- *Signal boosters.* In addition to or as an alternative to replacement antennas, some vendors also sell signal boosters that piggyback onto an existing access point or router. Note that, in most cases, these signal boosters are vendor specific.

Security and Other Features

When I was writing the original edition of *Upgrading and Repairing PCs*, the hackers' favorite way of trying to get into a network without authorization was discovering the telephone number of a modem on the network, dialing in with a computer, and guessing the password, as in the movie *War Games*. Today, *war driving* has largely replaced this pastime as a popular hacker sport. War driving is the popular name for driving around neighborhoods with a notebook computer equipped with a wireless network card on the lookout for unsecured networks. They're all too easy to find, and after someone gets onto your network, all the secrets in your computer can be theirs for the taking.

Because wireless networks can be accessed by anyone within signal range who has a NIC matching the same IEEE standard of that wireless network, wireless NICs and access points provide for encryption options. Most access points (even cheaper SOHO models) also provide the capability to limit connections to the access point by using a list of authorized MAC numbers (each NIC has a unique MAC), thus limiting access to authorized devices only.

Caution

In the past, it was thought that the SSID feature provided by the IEEE 802.11 standards was also a security feature. That's not the case. A Wi-Fi network's SSID is nothing more than a network name for the wireless network, much the same as workgroups and domains have network names that identify them. The broadcasting of the SSID can be turned off (when clients look for networks, they won't immediately see the SSID), which does provide a marginal security benefit. However, in general, the SSID should never be considered to be a security item in any way. In fact, many freely available (and quite powerful) tools exist that allow snooping individuals to quickly discover your SSID even if it's not being broadcast, allowing them to connect to your unsecured wireless network.

All Wi-Fi products support at least 40-bit encryption through the wired equivalent privacy (WEP) specification, but the minimum standard on recent products is 64-bit WEP encryption. Many vendors offer 128-bit or 256-bit encryption on some of their products. However, the 128-bit and stronger encryption feature is more common among enterprise products than small-office/home-office-oriented products. Unfortunately, the WEP specification has been shown to be notoriously insecure against determined hacking. Enabling WEP will keep a casual snooper at bay, but someone who wants to get into your wireless network won't have much trouble breaking WEP.

For that reason, all wireless network products introduced after 2003 incorporate a different security standard known as Wi-Fi Protected Access (WPA). WPA is derived from the developing IEEE 802.11i security standard. WPA-enabled hardware works with existing WEP-compliant devices, and software upgrades are often available for existing devices to make them WPA capable.

You should match the encryption level and encryption type used on both the access points and the NICs for best security. Remember that, if some of your network supports WPA but other parts support only WEP, your network must use the lesser of the two security standards (WEP). If you want to use the more robust WPA security, you must ensure that all the devices on your wireless network support WPA. Because WEP is easily broken and the specific WEP implementations vary between manufacturers, I recommend using only devices that support WPA.

Some products' access points can be managed via a web browser and provide diagnostic and monitoring tools to help you optimize the positioning of access points. Most products feature support for Dynamic Host Configuration Protocol (DHCP), allowing a user to move from one subnet to another without difficulties.

[Figure 18.23](#) illustrates how a typical IEEE 802.11 wireless network uses multiple access points.

Figure 18.23. A typical wireless network with multiple access points. As users with wireless NICs move from one office to another, the roaming feature of the NIC automatically switches from one access point to another, permitting seamless network connectivity without wires or logging off the network and reconnecting.

Users per Access Point

The number of users per access point varies with the product; Wi-Fi access points are available in capacities supporting anywhere from 15 to as many as 254 users. You should contact the vendor of your preferred Wi-Fi access point device for details.

Although wired Ethernet networks are still the least expensive network to build if you can do your own wiring, Wi-Fi networking is now cost-competitive with wired Ethernet networks when the cost of a professional wiring job is figured into the overall expense.

Because Wi-Fi is a true standard, you can mix and match access point and wireless NIC hardware to meet your desired price, performance, and feature requirements for your wireless network, just as you can for conventional Ethernet networks provided you match up frequency bands or use dual-band hardware.

Notebook Computers with Integrated Wi-Fi Adapters

Major notebook computer makers, including Dell, IBM, and Toshiba, are now integrating built-in 802.11b/g or 802.11a/b/g wireless adapters and antennas into most of their notebook computers. Although computers with built-in Wi-Fi hardware are a little more expensive than comparable models lacking Wireless Ethernet support, building the adapter and antenna into notebook computers provides for a more durable and less cumbersome way to equip portable systems than the normal PC Card and external antenna arrangement that must be fitted to notebook computers that don't have internal Wi-Fi support.

Most notebook computers with Wi-Fi hardware onboard use the mini-PCI interface for the wireless adapter and place the antenna inside the screen housing. This enables computers with built-in Wi-Fi hardware to have one more open PC Card slot than computers that must use an external PC Card adapter and antenna.

Network Protocols

Not so long ago the second-most important choice you had to make when you created a network was which network protocol to use because the network protocol affects which types of computers your network can connect. Today, the choice has largely been made for you.

The three major network protocols are TCP/IP, IPX/SPX, and NetBEUI. Unlike data-link protocols, though, network protocols are not tied to particular hardware (NIC or cable) choices. Network protocols are software and can be installed to or removed from any computer on the network at any time as necessary. Today, TCP/IP has evolved to become the dominant protocol for large and small networks alike. [Table 18.9](#) summarizes the differences between these protocols.

Table 18.9. Overview of Network Protocols and Suites

Protocol	Best Used for	Notes
TCP/IP	Most Windows-based networks	Native protocol suite for Windows 2000/XP and Novell NetWare 5.x/6.x; also used for dial-up Internet access
IPX/SPX	Novell 4.x and earlier networks	Used by NetWare 5.x for certain special features only
NetBIOS	Older Windows for Workgroups or DOS-based peer networks	Simplest protocol; can't be routed between networks; also used with Direct Cable Connection "networking"

All the computers on any given network must use the same network protocol or protocol suite to communicate with each other.

IP and TCP/IP

IP stands for Internet Protocol; it is the network layer of the collection of protocols (or protocol suite) developed for use on the Internet and commonly known as TCP/IP (Transmission Control Protocol/Internet Protocol).

Later, the TCP/IP protocols were adopted by the Unix operating systems, and they have now become the most commonly used protocol suite on PC LANs. Virtually every operating system with networking capabilities supports TCP/IP, and it is well on its way to displacing all the other competing protocols. Novell NetWare 6 and Windows XP both use TCP/IP as their native protocol for most services.

TCP/IP LAN and Dialup Networks

TCP/IP, unlike the other network protocols listed in the previous section, is also a protocol used by people

who have never seen a NIC. People who access the Internet via modems (with what Windows 9x calls Dial-Up Networking) use TCP/IP just as those whose web access is done with their existing LANs. Although the same protocol is used in both cases, the settings vary a great deal.

[Table 18.10](#) summarizes the differences you're likely to encounter. If you access the Internet with both modems and a LAN, you must ensure that the TCP/IP properties for modems and LANs are set correctly. You also might need to adjust your browser settings to indicate which connection type you are using. [Table 18.10](#) provides general guidelines; your ISP or network administrator can give you the specific details.

Table 18.10. TCP/IP Properties by Connection Type**Overview**

TCP/IP Property Tab	Setting	Modem Access (Dialup Adapter)	LAN Access (Network Card)
IP Address	IP Address	Automatically assigned by ISP	Specified (get value from network administrator) or automatically assigned by a DHCP server on the network (DHCP servers are often built in to gateways and routers)
WINS Configuration	Enable/Disable WINS Resolution	Disabled	Indicate server or enable DHCP to allow NetBIOS over TCP/IP
Gateway	Add Gateway/List of Gateways	Automatically assigned by ISP	IP address of gateway used to connect LAN to Internet
DNS Configuration	Enable/Disable Host Domain	Automatically assigned by ISP	Enabled, with host and domain specified (get value from network administrator)

As you can see from [Table 18.10](#), correct settings for LAN access to the Internet and dialup networking (modem) settings are almost always completely different. In general, the best way to get your dialup networking connection working correctly is to use your ISP's automatic setup software. This is usually supplied as part of your ISP's sign-up software kit. After the setup is working, view the properties and record them for future troubleshooting use.

Note

In Windows 98 and Me, Microsoft recommends that TCP/IP properties be viewed through the Dial-Up Networking icon for the connection, rather than through the Network icon in the Control Panel. This is because different dialup connections could use different TCP/IP properties, which would override the default properties for the Dial-Up Adapter listing in the Network properties.

In Windows 2000 and XP, all types of networking are viewed and configured through a single

interface.

IPX

The IPX protocol suite (often referred to as IPX/SPX) is the collective term for the proprietary protocols Novell created for its NetWare operating system. Although based loosely on some of the TCP/IP protocols, Novell privately holds the IPX protocol standards. However, this has not prevented Microsoft from creating its own IPX-compatible protocol for the Windows operating systems.

IPX (Internetwork Packet Exchange) itself is a network layer protocol that is equivalent in function to IP. The suite's equivalent to TCP is the Sequenced Packet Exchange (SPX) protocol, which provides connection-oriented, reliable service at the transport layer.

The IPX protocols typically are used today only on networks with NetWare servers running older versions of NetWare and often are installed along with another protocol suite, such as TCP/IP. Novell has phased out its use of IPX for NetWare support and switched to TCP/IP along with the rest of the networking industry starting with NetWare 5. NetWare 5 uses IPX/SPX only for specialized operations. Most of the product uses TCP/IP. NetWare version 6 and above use TCP/IP exclusively.

NetBEUI

NetBIOS Extended User Interface (NetBEUI) is a protocol that was used primarily on small Windows NT networks, as well as on peer networks based on Windows for Workgroups and Windows 9x. It was the default protocol in Windows NT 3.1, the first version of that operating system. Later versions, however, use the TCP/IP protocols as their default.

NetBEUI is a simple protocol that lacks many of the features that enable protocol suites such as TCP/IP to support networks of almost any size. NetBEUI is not routable, so it can't be used on large internetworks. It is suitable for small peer-to-peer networks, but any serious Windows NT/2000/XP network installation should use TCP/IP.

NetBEUI is still useful for creating "instant networks" with the Direct Cable Connection (see the following), and it is the minimum protocol required for use in a Windows 9x peer-to-peer network.

[< PREV](#)[NEXT >](#)

Other Home Networking Solutions

If you are working at home or in a small office, you have an alternative to hole-drilling; pulling specialized network cabling; and learning how to configure TCP/IP, IPX, or NetBEUI protocols.

So-called "home" networking is designed to minimize the complexities of cabling and protocol configuration by providing users with a sort of instant network that requires no additional wiring and configures with little technical understanding.

HomePNA

Other than using Ethernet (wired or wireless), the most popular form of home networking involves adapting existing telephone wiring to networking by running network signals at frequencies above those used by the telephone system. Other, less popular forms of home networking piggyback on household or office electrical wiring or are wireless, taking advantage of previously unused parts of the electromagnetic spectrum.

Because it is the most developed and most broadly supported type of home networking, this discussion focuses on the HomePNA standards the Home Phoneline Networking Alliance (<http://www.homepna.org>) has created. This alliance has most of the major computer hardware and telecommunications vendors among its founding and active membership.

A companion website focusing on products that use HomePNA standards is <http://www.homepna.com>.

The Home Phoneline Networking Alliance has developed two versions of its HomePNA standard. Both versions are designed to work over existing telephone lines, but they have big differences in speed and hardware usage.

HomePNA 1.0

The original HomePNA standard, introduced in 1998, was designed to make home networking as much of a no-brainer as possible. HomePNA 1.0 has a speed of just 1Mbps, which is just 1/10 the speed of 10BASE-T or other forms of standard Ethernet. HomePNA 1.0 was designed for ease of use rather than performance and utilized parallel ports, USB ports, and PCI cards for use with desktop computers, and PC Card (PCMCIA) devices for use with notebook computers. HomePNA 1.0 is now obsolete, having been replaced by HomePNA 2.0; HomePNA 1.0 products can be used on the same network as HomePNA 2.0 products.

HomePNA 2.0

HomePNA 2.0-compatible products began to appear in late 1999. HomePNA 2.0 runs up to 10Mbps, making it comparable to standard Ethernet speeds, and is implemented through 32-bit PCI network cards for desktop computers and PC Card devices for use with notebook computers (see [Figure 18.24](#)). The newest HomePNA 2.0-compatible devices include broadband modems, Internet appliances, and broadband gateways. Some home-office computers include HomePNA 2.0 interface cards.

Figure 18.24. A typical HomePNA 2.0 PC Card network adapter from Linksys.
Photo courtesy Linksys.

HomePNA 2.0-compatible products are fast enough to make Internet connection sharing a workable reality and are backward-compatible with HomePNA 1.0 products.

After HomePNA network adapters are installed, they use the same network protocols as do other adapters. A default installation might install only the nonrouteable NetBEUI protocol, but if you use your HomePNA network to share an Internet connection (see [Figure 18.25](#) in the following section), you will also need to install the TCP/IP protocol on each computer if it is not already installed. See the documentation for your HomePNA router for details on installation and client configuration.

Figure 18.25. A typical HomePNA network with three stations; this network enables data and peripheral sharing and shared access to a broadband Internet cable or DSL modem.

Note

In May 2005, the HomePNA announced that a forthcoming 3.0 standard had been approved by the International Telecommunication Union with the aim of providing a single worldwide standard for home networking via phone lines. The aim of this standard is to provide data rates of up to 240Mbps along with quality of service (QoS) adequate to support VoIP and transmission of HDTV-quality video.

HomePNA Topology

HomePNA uses a simplified form of the bus topology described earlier in this chapter. The telephone wiring is the backbone of a HomePNA network, and each HomePNA network adapter has two connectors: one that connects to the telephone wiring in the wall and another that enables you to plug a telephone into the adapter and use the phone at the same time as the network is active. This pass-through feature is similar to that found on most telephone modems. [Figure 18.25](#) illustrates a typical HomePNA network being used to share a broadband Internet connection.

◀◀ For more information about sharing Internet access and broadband Internet devices, see [Chapter 17](#), "Internet Connectivity," p. [1053](#).

Powerline Networking

Home networking via power lines has been under development for several years, but electrical interference, inconsistent voltage, and security issues made the creation of a workable standard difficult until mid-2001. In June 2001, the HomePlug Powerline Alliance, a multivendor industry trade group, introduced its HomePlug 1.0 specification for 14Mbps home networking using power lines. The HomePlug Powerline Alliance (www.homeplug.org) conducted field tests in about 500 households early in 2001 to develop the HomePlug 1.0 specification.

HomePlug 1.0 is based on the PowerPacket technology developed by Intellon. PowerPacket uses a signaling method called *orthogonal frequency division multiplexing (OFDM)*, which combines multiple signals at different frequencies to form a single signal for transmission. Because OFDM uses multiple frequencies, it can adjust to the constantly changing characteristics of AC power. To provide security, PowerPacket also supports 56-bit DES encryption and an individual key for each home network. By using PowerPacket technology, HomePlug 1.0 is designed to solve the power quality and security issues of concern to a home or small-office network user. Although HomePlug 1.0 is rated at 14Mbps, typical real-world performance is usually around 4Mbps for LAN applications and around 2Mbps when connected to a broadband Internet device such as a cable modem.

HomePlug 1.0 products include USB and Ethernet adapters, bridges, and routers, enabling most recent PCs with USB or Ethernet ports to use powerline networking for LAN and Internet sharing. Linksys was the first to introduce HomePlug 1.0 products in late 2001; other leading vendors producing HomePlug hardware include Phonex, NetGear, and Asoka. HomePlug 1.0-certified products bear the HomePlug certification label seen in [Figure 18.26](#).

Figure 18.26. The HomePlug Powerline Alliance 1.0 (14Mbps) certification mark.

An improved HomePlug AV specification with support for faster speeds (up to 100Mbps), multimedia hardware, and guaranteed bandwidth for multimedia applications was announced in the fall of 2002; the final HomePlug AV specification was approved in August 2005.

Putting Your Network Together

You've bought or built your cables, bought your NICs and hub, and located your Windows CD-ROM. Now it's time to make your network a reality!

In this section is a detailed checklist of the hardware and software you need to build your network.

First, start with the number of computers you plan to network together. You need the items discussed in the following sections to set up your network.

Network Adapter

You need a network adapter for every computer on the network that doesn't have a network port or wireless network adapter already included; if the computer has a built-in network port or wireless network adapter, be sure it will work with your network.

Traditionally, network adapters are also called network interface cards (NICs), but the widespread use of USB devices and built-in ports makes this term less accurate. To simplify technical support, use the same model of NIC for each computer in your network (if possible). If you are creating a Windows Server or Novell NetWare network with a dedicated server, you should buy server-optimized NICs for the server and less-expensive client NICs for the client PCs. However, you should still purchase the same brand to simplify support issues. Some vendors use the same driver for both their server and client NICs, further simplifying your support issue.

For the best performance, I recommend that you use PCI-based NICs for desktop computers or PC Card CardBus NICs for notebook computers with CardBus slots (CardBus and PCI slots have a 32-bit wide data bus, whereas typical PC Card slots have a 16-bit data bus). USB devices are more convenient, but USB 1.1 devices are much slower than 10/100 Ethernet. USB 2.0 devices are a satisfactory substitute for 10/100 Ethernet but require that both the computer and the device be USB 2.0compliant to achieve the 480Mbps speed of USB 2.0. If either the device or the computer is only USB 1.1compliant, the connection is limited to 12Mbps.

You should record the brand name and model number of the network adapters you are using, as well as the driver version or source. Use [Table 18.11](#) in the "[Recording Information About Your Network](#)" section, later in this chapter, as a template for storing this information.

Table 18.11. Network Hardware Worksheet

Network Type:	Number of Stations:	Internet Sharing:	
Computer Location/ID:	Brand Name/Model:	NIC Brand/Model:	Speed:
Driver:	Cable Type/Wiring Standard:	Cable Length:	

Hub/Switch Location/ ID:	Hub/Switch Brand/ Model:	Hub/Switch Speed:
<hr/>	<hr/>	<hr/>
No. Ports:	Hub or Switch:	
<hr/>	<hr/>	
Router Location/ID:	Router Brand/Model:	Router Speed:
<hr/>	<hr/>	<hr/>
No. Ports:	Router IP Address:	Router Password:
<hr/>	<hr/>	<hr/>

Installing the Network Adapter

Before you can connect computers to the network, you must install network adapters. If the network adapter is an internal card, follow this procedure:

1.

Open the case and locate an open expansion slot that matches the type of NIC you purchased (preferably PCI).

2.

Using a screwdriver, remove the screw securing the slot cover at the rear of the case.

3.

Insert the card gently, ensuring that the edge connector is seated solidly in the slot.

4.

Fasten down the card with the same screw that held the slot cover.

See [Figures 20.26](#) and [20.27](#) in [Chapter 20](#), "Building or Upgrading Systems," p. [1256](#), for an example of installing an add-on card.

Tip

If you are a realist like me, you might not want to close the case until you are certain the NIC is working (see the next section, "Testing Your Network Adapters and Connections").

A NIC uses the same hardware configuration settings most other expansion cards use:

- An IRQ
- An I/O port address range

Note

Some older network cards might require an upper memory block range for RAM buffers. Cards used on diskless workstations use a boot ROM, which also requires an upper memory block range. See your network card's documentation to find out whether this issue applies to you.

If you are using Windows 9x or newer with a PnP (Plug and Play) BIOS and a PnP NIC, the computer and Windows configure your card for you in most cases. In a few cases, you might need to adjust PnP settings in the BIOS, and in a rare case you might even need to remove your other PnP cards and put the NIC in first if your system doesn't recognize it after you restart the system.

◀◀ For general BIOS information, see [Chapter 5](#), "BIOS," p. [411](#), or see your system manual for details about your computer's BIOS.

If you install the card in a non-PnP system or under Windows NT, be sure the card comes with configuration software or manual switch settings for hardware configuration. A pure PnP card can't be installed on a system that lacks PnP support.

USB and PC Card/CardBus network adapters are automatically detected and installed when connected because USB ports and PC Card/CardBus slots are hot-swap connections.

And, if you are using an older network adapter with Windows XP, you might need to download drivers from the adapter vendors' websites. Even if you have drivers for your current version of Windows, getting the latest driver release will help you avoid setup and installation problems.

Testing Your Network Adapters and Connections

The configuration software disk or CD-ROM included with the network adapter usually features diagnostic software. Some diagnostics should be performed before the card is connected to the network and should be run from a command prompt.

After the network adapter passes these tests, connect the network adapter to the network. With an Ethernet network using UTP cable, run the cable from the card to the hub or switch, turn on the computer and hub, and watch for signal lights to light up on the NIC's back bracket (if so equipped) and on the hub or switch. Hubs and switches use green LEDs to indicate the presence of a computer on a particular RJ-45 port. Connect a second computer with NIC installed to the hub or switch. Then, run the diagnostics program on both computers to send and receive data. For other types of networks, see the diagnostics provided with the network hardware for testing details.

Cables and Connections Between Computers

Depending on the network architecture you choose, you might need to run cables. If you are installing a 100BASE-TX, or 1000BASE-TX Ethernet network (both of which use UTP cables), you need cables that are long enough to reach comfortably between each computer's network port and the network's hub or switch. Use [Table](#)

[18.11](#) in the "[Recording Information About Your Network](#)" section, later in this chapter, as a template for storing this information.

Because HomePNA networks are based on your existing telephone line, the patch cord included with the NIC is usually long enough to connect with your existing RJ-11 telephone jack. The HomePNA NIC has two jacks: one for the connection to the telephone line and the other to enable you to connect your telephone to the NIC. Be sure you use the correct jack for each cable; otherwise, your network won't work. HomePNA enables you to use your telephone system for voice and networking at the same time.

Wireless network NICs use an external antenna to make the connection between computers. In some cases, the antenna is built in to the NIC, whereas in other cases the antenna is attached to the NIC or needs to be extended from a storage position inside the NIC.

Hub/Switch/Access Point

UTP Ethernet networks require a hub or switch if more than two computers will be networked (you can use a crossover cable between two computers only). Wireless Ethernet networks also require an access point if more than two computers will be networked, or if the network will be used to share an Internet connection.

For a UTP-based Ethernet network, buy a hub or switch (preferred) of the correct speed with at least enough RJ-45 ports for each computer on the network. For a wireless Ethernet network, you will need at least one access point, depending on the range of your wireless network. Most IEEE 802.11b/Wi-Fi network access points have a range of 150 feet indoors (and up to 300 feet outdoors), which should be adequate for most homes and many small businesses. You can add more access points if you need a wider area of coverage.

If you are going to use the network to share Internet access, you can save money if you buy a router that contains a switch for a wired Ethernet network or a wireless access point that contains a router for a wireless Ethernet network.

Use [Table 18.11](#) in the "[Recording Information About Your Network](#)" section as a template for storing this information. [Table 18.11](#) also provides a space for recording whether you plan to use the network for Internet sharing.

Gateways for Non-Ethernet Networks

If you plan to share Internet access through a non-Ethernet network such as HomePNA or HomePlug and you don't want to use a software-sharing solution such as Microsoft Internet Connection Sharing, you must install a gateway or router between the broadband device (such as a cable or DSL modem) and your network. Some gateway/router devices can also act as print servers; in addition, some, such as those from 2Wire, support HomePNA, Ethernet, or Wi-Fi networks.

Recording Information About Your Network

Networks are terrific when they work, but they're a potential nightmare when they fail. By keeping careful notes about network configuration, you can reinstall network drivers, set up new computers on the network, and handle other network crises without breaking a sweat.

Use the worksheet shown in [Table 18.11](#) as a guide for recording information about your network hardware.

Installing Networking Software

To access network resources with a PCwhether it is connected to a client/server or peer-to-peer networkyou must install network client software on the computer. The network client can be part of the operating system or a separate product, but it is this software that enables the system to use the network interface adapter to communicate with other machines.

On a properly configured network workstation, accessing network resources is no different from accessing local ones (except that they might be slightly slower). You can open a file on a network drive just as you would open the same file on your local hard disk. This is because the network client software is completely integrated into every level of the computer's operating system.

In most cases, the network client software is part of the operating system. Windows 9x, NT, 2000, and XP, for example, include all the software you need to participate in a peer-to-peer Windows network or to connect to Windows NT, Windows 2000, Windows Server 2003, and Novell NetWare servers. To connect to a network using DOS or Windows 3.1, however, you must install a separate client software package.

When you install a NIC under Windows 95 or Windows 98, the following network protocols are installed by default:

- NetBEUI
- TCP/IP
- IPX/SPX

Windows Me, Windows 2000, and Windows XP use TCP/IP by default. If you need to install particular protocols or other network components, use the Networks icon in the Windows Control Panel or right-click the Network Neighborhood (Windows 9x) or My Network Places (Windows Me/2000) icon on the Windows desktop and select Properties. If you need to use NetBEUI with Windows XP, it must be manually installed from the Windows XP CD-ROM.

Configuring Your Network Software

You might have a few problems installing your NICs. They might pass their diagnostics flawlessly, but until each station on your network can speak the same language, has correct client or server software setups, and uses the same protocols, your network will not function properly.

[Table 18.12](#) shows the minimum network software configuration you must install for Windows 9x/Me, Windows NT, Windows 2000, and Windows XP peer-to-peer networking.

Table 18.12. Minimum Network Software for Peer-to-Peer Networking

Item	Workstation	Server
Windows Network client	Yes	No
NetBEUI or TCP/IP ^[*] protocol	Yes	Yes
File and print sharing for Microsoft Networks	No	Yes
NIC installed and bound to protocols and services above	Yes	Yes

Workgroup identification (same for all PCs in workgroup)	Yes	Yes
Computer name (each PC needs a unique name)	Yes	Yes

^[*] If TCP/IP is used as the standard protocol, each workstation must have a different IP address either manually assigned or received from a DHCP server built in to a server, router, or gateway computer or device.

Although the networking settings in [Table 18.12](#) enable a Windows peer-to-peer network to function, you might need to add more networking components. If the computer can access a Novell NetWare client/server network running NetWare 4.x, the IPX/SPX protocol must also be installed. It also might be required for certain operations with NetWare 5. If the computer is used to access the Internet or any other TCP/IP-based network, the TCP/IP protocol must also be installed. In most cases, you can now use TCP/IP as the only network protocol because it can be used for both Internet and LAN access.

Use the Network icon in the Windows Control Panel to select your network settings. To set up your network, you'll need the operating system CDs, disks, or hard-disk image files and the network adapter drivers. (Workgroup hubs and switches require no software.)

To install a network component, follow this procedure:

1. Open the Network icon in the Control Panel.
2. The Configuration tab is displayed; select Add.
3. Select from the following:
 - *Client*. Select if you want to install the Microsoft or other network clients for your network. Every PC on a peer-to-peer network needs the Client for Microsoft Networks.
 - *Adapter*. This should already be installed, but you can use this to install a new adapter.
 - *Protocol*. For a simple, non-Internet network with versions of Windows before XP, install NetBEUI. If you want to use Internet Connection Sharing along with networking, install both TCP/IP and NetBEUI. With Windows XP, use the Network Setup Wizard to configure TCP/IP easily.
 - *Service*. Install File and Printer Sharing for Microsoft Networks on any computer that will be used as a server.
4. Click the Identification tab. Enter a unique name for each computer on the network; use the same workgroup name for all computers on the network.
5. Click OK. Supply the Windows CD-ROM or other media as necessary to install the network components you requested.
6. You are prompted to insert a CD or disk or browse to the appropriate files during the installation procedure, if they're not available on the Windows 9x CD-ROM or on your hard disk in the default location.

You might need to reboot your PC to complete the process, particularly if you're using Windows 9x or Me. After this is completed, you'll be ready to share resources.

After the network hardware and software installation is complete, your network is ready to use. However, if you

are using Windows NT, Windows 2000, or Windows XP Professional, you must set up users and groups for security. Windows 9x, Me, and Windows XP Home use peer-to-peer access control, which can be protected with passwords if you desire.

For more information about these processes, see "Configuring Users, Groups, and Resources" in the Technical Reference section of the disc packaged with this book.

Tips and Tricks

Network configuration can take a long time unless you have a few tricks up your sleeve. Use this section to help you find faster, easier, and better ways to set up and use your network.

Installation

- If you are setting up several systems with identical hardware, NICs, and software, consider making an image file of the first system after you complete its installation with a program such as Drive Image Professional, and then connecting the other computers and "cloning" the first computer's hard disk to each additional system. Check with the imaging software vendor for details.
- Don't click OK in the Windows Networks properties sheet until you have made all the changes you want to make (see the previous list) on a Windows 9x or Me system. Whenever you click OK, you are prompted to reboot the system to apply the changes.
- If you're salvaging old 10BASE-T Ethernet cards for a network, use Category 5 UTP and dual-speed hubs to make switching to Fast Ethernet in the future easier. I recommend this only if your systems use ISA cards; new 10/100 Ethernet cards cost less than \$20 each.

Sharing Resources

- If you want to have network drives or folders show up as part of My Computer so you can search them and see them easily in Windows Explorer, map a drive letter to each one. This step is desirable with any combination of operating systems and is a virtual necessity on networks in which Windows 2000 or Windows XP computers are accessing shared resources on a Windows 9x computer. Browsing the network is very slow without mapped drives, but access to shares through a mapped drive letter is very fast.
- To more easily keep drive mappings straight, I use the drive letter I plan to use for mapping on other workstations as the name of the shared resource on my peer server. In other words, if I want to map the D: drive on my peer server as "P:", I name it "P" when I set its sharing properties. Then, as I view the folder from another computer, I know from its name that I should map it as "P:". This enables multiple PCs to easily map the same resource as the same drive letter on different systems, which makes it easier if people in your office play musical computers.

Setting Up Security

- If you're building a peer-to-peer network, keep in mind that passwords are the only way to keep unwanted users out of your system.
- Create a group of several users and assign rights on a group basis when you have several users who need the same access rights.

Sharing Internet Connections

- If you are planning to share an Internet connection using Microsoft Internet Connection Sharing or other computer-based sharing programs, *don't* set up File and Printer Sharing on the computer that does the sharing (the proxy server or gateway computer); share drives on other computers instead, or install a self-contained network storage device. Refer to [Chapter 17](#) for software you can add to your computer to keep it safe on the Internet.
- Routers and gateway devices are an economical way to share broadband access in a home or small

office, and they are easier to manage and more reliable than using ICS or other sharing programs. Routers and gateways can also act as firewalls to protect your computer from unauthorized access from the Internet.

Direct Cable Connections

Direct Cable Connection is a technology that enables you to connect two PCs together via their serial, parallel, or IR ports to make an instant network. Windows 9x, Me, 2000, and XP all include Direct Connect client and server software, but special parallel (preferred) or serial cables are required; IR (infrared) ports on notebook computers can also be used for direct connections. See the section "[Direct Cable Connections](#)" in [Chapter 17](#), "Local Area Networking," of *Upgrading and Repairing PCs, 12th Edition*, included on this book's disc, for details.

Troubleshooting a Network

The following sections list a series of common networking problems along with solutions that can usually set things right again.

Network Software Setup

Problem

Duplicate computer names.

Solution

Make sure that every computer on the network has a unique name. Otherwise, you'll get an error message when you reboot the workstations with networking cables attached. (You can change the computer name from the System applet of the Control Panel, although you must restart the system for it to be effective.)

Problem

Different workgroup names.

Solution

Make sure every computer that's supposed to be working together has the same workgroup name. The Windows 9x/NT Network Neighborhood and Windows Me/2000/XP My Network Places icons display computers by workgroup name. Different workgroup names actually create different workgroups, and you'd need to access them by browsing via Entire Network. You can also make this change from the System applet, although it too requires rebooting the system to become effective.

Problem

Shared resources are not available.

Solution

Make sure that shared resources have been set for any servers on your network (including peer servers on Windows 9x). If you can't share a resource through Windows Explorer on the peer server, ensure that File and Printer Sharing has been installed.

Problem

Network doesn't work after making changes.

Solution

Did you reboot? Any change in the Network icon in Windows 9x/Me Control Panel requires a system reboot!

Did you log in? Any network resources can't be accessed unless you log in when prompted. You can use Start, Shutdown, and Close All Programs and Logon As a New User with Windows 9x/Me to recover quickly from a failure to log on.

Networks in Use

Problem

A user can't access any shared resources (but others can).

Solution

First, have the user log off and log back on. Pressing Cancel or Esc instead of logging in would keep a user off the network.

Next, check cable connections at the server and workstation. Loose terminators or BNC T-connectors can cause trouble for all workstations on a Thinnet cable segment. A loose or disconnected RJ-45 cable affects only the computer (or hub) using it. If a Category 5 UTP cable seems to be connected tightly but the user still can't get on the network, check the cable with a cable tester or replace the cable.

Problem

Wrong access level.

Solution

If you save your passwords in a password cache, entering the read-only password instead of the full-access password limits your access with peer servers. Try unsharing the resource and try to reshare it, or have the user of that peer server set up new full-access and read-only passwords. Alternatively, don't use password caching by unchecking the Save Password box when you log on to a shared resource. With a client/server network with user lists and rights, check with your network administrator because she will need to change the rights for you.

TCP/IP

Problem

Incorrect settings in Network Properties.

Solution

Get the correct TCP/IP settings from the administrator and enter them; restart the PC if you're using Windows 9x. Windows 2000 and newer do not require the PC to be restarted after changing TCP/IP settings.

Problem

Can't keep connection running in Dial-Up Networking.

Solution

You might have the wrong version of PPP running; change the server type in Properties under Dial-Up Networking, not Networks.

Problem

Message about duplicate IP addressescan't connect to anything.

Solution

Duplicate IP addresses disable both TCP/IP and NetBEUI networking. Internet sharing products such as ICS, third-party sharing programs, and routers are usually configured to assign IP addresses automatically to avoid duplication. If some computers on a network have fixed IP addresses and others have dynamically assigned IP addresses, conflicts could occur. The entire network should use dynamic IP addressing (DHCP) or each computer should be assigned a unique IP address.

Problem

No error messagecan't connect to Internet or other computers.

Solution

Check the router, switch, or hub used to connect the computers to each other and the Internet. It needs to be powered, and the data cables must be properly connected between it and each PC (and between the Internet connection and the switch or hub, if applicable).

If your network uses DHCP to dynamically assign IP addresses and the router has lost power or connection, users won't have valid IP addresses. Restart the router, and have all users log off and shut down. When they restart their systems, they should be able to obtain valid IP addresses and connect with each other.

Chapter 19. Power Supplies

[Considering the Importance of the Power Supply](#)

[Power-Protection Systems](#)

[RTC/NVRAM \(CMOS RAM\) Batteries](#)

Considering the Importance of the Power Supply

The power supply is not only one of the most important parts in a PC, but it is unfortunately also the most overlooked. The power supply, in the words of the late Rodney Dangerfield, gets no respect! People spend hours discussing their processor speeds, memory capacity, disk storage capacity and speed, video adapter performance, monitor size, and so forth but rarely even mention or consider their power supply. When a system is put together to meet the lowest possible price point, what component do you think the manufacturer skimps on? Yes, the power supply. To most people, the power supply is a rather nondescript, unglamorous metal box that sits inside their systems, something to which they pay virtually no attention at all. The few who do pay any mind seem concerned only with how many watts of power it is rated to put out (even though no practical way exists to verify those ratings), without regard to whether the power being produced is clean and stable or whether it is full of noise, spikes, and surges.

I have always placed great emphasis on selecting a power supply for my systems. I consider the power supply the core of the system and am willing to spend more to get a better unit. The power supply function is critical because it supplies electrical power to every other component in the system. In my experience, the power supply is also one of the most failure-prone components in any computer system. I have replaced more power supplies in PCs than any other part. This is especially due to the fact that, to keep system prices down, system builders are encouraged to use the cheapest power supplies they can find. A malfunctioning power supply can not only cause other components in the system to malfunction, but also can damage the other components in your computer by delivering an improper or erratic voltage. Because of its importance to proper and reliable system operation, you should understand both the function and limitations of a power supply, as well as its potential problems and their solutions.

This chapter covers the power supply in detail. I focus on the electrical functions of the supply and the mechanical form factors and physical designs that have been used in PC systems in the past, as well as today. Because the physical shape (*form factor*) of the power supply relates to the case, some of this information also relates to the type of chassis or case you have.

Recently the industry-standard ATX power supply used in PCs has been evolving, with new connectors appearing on newer power supplies as well as motherboards and video cards. There are adapters to convert the new power connectors to the old ones (and vice versa). However, in virtually all cases these adapters aren't necessary because, by virtue of their design, several of the old and new connectors are actually compatible. For those who are either building new systems from scratch or upgrading and repairing existing systems, knowledge of the new connectors and how you can almost always build, upgrade, or repair a system without purchasing unnecessary adapters will be invaluable. This chapter examines the evolutionary changes to the ATX power supply connectors and highlights the new connectors designed for the latest systems.

Primary Function and Operation

The basic function of the power supply is to convert the type of electrical power available at the wall socket to the type the computer circuitry can use. The power supply in a conventional desktop system is designed to convert either 120-volt (nominal) 60Hz AC (alternating current) or 240V (nominal) 50Hz AC power into +3.3V, +5V, and +12V DC (direct current) power. Some power supplies require you to switch between the two input ranges, whereas others auto-switch.

Technically, the power supply in most PCs is described as a *constant voltage switching power supply*, which is defined as follows:

- *Constant voltage* means the power supply puts out the same voltage to the computer's internal components, no matter the voltage of AC current running it or the capacity (wattage) of the power supply.
- *Switching* refers to the design and power regulation technique that most suppliers use. Compared to other types of power supplies, this design provides an efficient and inexpensive power source and generates a minimum amount of heat. It also maintains a small size and low price.

Positive DC Voltages

Usually, the digital electronic components and circuits in the system (motherboard, adapter cards, and disk drive logic boards) use the +3.3V or +5V power, and the motors (disk drive motors and any fans) use the +12V power. [Table 19.1](#) lists these devices and their power consumptions.

Table 19.1. Power Consumption Ratings for PC Devices

Voltage	Devices Powered
+3.3V	Chipsets, DIMMs, PCI/AGP cards, miscellaneous chips
+5V	Disk drive logic, SIMMs, PCI/AGP cards, ISA cards, voltage regulators, miscellaneous chips
+12V	Motors, voltage regulators (high output)

The power supply must deliver a good, steady supply of DC power so the system can operate properly. Devices that run on voltages other than these must be powered by onboard voltage regulators. For example, RIMMs and DDR dual inline memory modules (DIMMs) require 2.5V, DDR2 DIMMs require 1.8V, AGP 4x/8x cards require 1.5V, and PCI Express cards use only 0.8V differential signalingall of which are supplied by simple onboard regulators. Processors also require a wide variety of voltages (as low as 1.3V or less) that are supplied by a sophisticated voltage regulator module (VRM) that is either built in or plugged in to the motherboard as well. You'll commonly find three or more different voltage regulator circuits on a modern motherboard.

Note

When Intel began releasing processors that required a +3.3V power source, power supplies that supplied the additional output voltage were not yet available. As a result, motherboard manufacturers began adding voltage regulators to their boards, which converted +5V current to +3.3V for the processor. When other chips began using 3.3V as well, Intel created the ATX power supply specification, which supplied 3.3V to the motherboard. You would think that having 3.3V direct from the power supply would have eliminated the need for onboard voltage regulators, but by that time, processors, memory, and other components began running on a wide variety of voltages lower than 3.3V. Motherboard manufacturers then included adaptable regulator circuits called voltage regulator modules to accommodate the widely varying processor voltage requirements. Additional regulators are also used to power any other devices on the motherboard that don't use +3.3V, +5V, or +12V.

See "[CPU Operating Voltages](#)," p. [101](#).

Negative DC Voltages

If you look at a specification sheet for a typical PC power supply, you can see that the supply generates not only +3.3V, +5V, and +12V, but also 12V and possibly 5V. The positive voltages seemingly power everything in the system (logic and motors), so what are the negative voltages used for? The answer is, not much! In fact, most recent power supply standards no longer include the 5V output for that reason. The only reason it remained in most power supply designs for many years is that 5V was required on the Industry Standard Architecture (ISA) bus for full backward compatibility. Because modern PCs no longer include ISA slots, the 5V signal is no longer necessary.

Although 12V and possibly 5V are supplied to the motherboard via the power supply connectors, the motherboard normally uses only the +3.3V, +5V, and +12V. If present, the 5V is simply routed to the ISA bus on pin B5 so any ISA cards can use it, even though very few ever did. However, as an example, the analog data separator circuits found in older floppy controllers did use 5V.

The motherboard logic typically doesn't use 12V either; however, it might be used in some board designs for serial port or LAN circuits.

Note

The load placed on the 12V output by an integrated LAN adapter is very small. For example, the integrated 10/100 Ethernet adapter in the Intel D815EEAL motherboard uses only 10mA of +12V and 10mA of 12V (0.01 amps each) to operate.

Although older serial port circuits used +/-12V outputs, today most run only on +3.3V or +5V.

The main function of the +12V power is to run disk drive motors as well as the higher-output processor

voltage regulators in some of the newer boards. Usually, a large amount of +12V current is available from the power supply, especially in those designed for systems with a large number of drive bays (such as in a tower configuration). Besides disk drive motors and newer CPU voltage regulators, the +12V supply is used by any cooling fans in the system which, of course, should always be running. A single cooling fan can draw between 100mA and 250mA (0.10.25 amps); however, most newer fans use the lower 100mA figure. Note that although most fans in desktop systems run on +12V, portable systems can use fans that run on +5V or even +3.3V.

Systems with motherboard form factors based on the ATX or BTX standard include another special signal. This feature, called PS_ON, can be used to turn the power supply (and thus the system) on or off via software. It is sometimes known as the *soft-power feature*. PS_ON is most evident when you use it with an operating system such as Windows that supports the Advanced Power Management (APM) or Advanced Configuration and Power Interface (ACPI) specification. When you select the Shut Down the Computer option from the Start menu, Windows automatically turns off the computer after it completes the OS shutdown sequence. A system without this feature only displays a message that it's safe to shut down the computer.

The Power_Good Signal

In addition to supplying electrical power to run the system, the power supply also ensures that the system does not run unless the voltages supplied are sufficient to operate the system properly. In other words, the power supply actually prevents the computer from starting up or operating until all the power supply voltages are within the proper ranges.

The power supply completes internal checks and tests before allowing the system to start. If the tests are successful, the power supply sends a special signal to the motherboard, called Power_Good. This signal must be continuously present for the system to run. Therefore, when the AC voltage dips and the power supply can't maintain outputs within regulation tolerance, the Power_Good signal is withdrawn (goes low) and forces the system to reset. The system will not restart until the Power_Good signal returns.

The Power_Good signal (sometimes called Power_OK or PWR_OK) is a +5V (nominal) active high signal (with a variation from +2.4V through +6.0V generally being considered acceptable) that is supplied to the motherboard when the power supply has passed its internal self tests and the output voltages have stabilized. This typically takes place anywhere from 100ms to 500ms (0.10.5 seconds) after you turn on the power supply switch. The power supply then sends the Power_Good signal to the motherboard, where the processor timer chip that controls the reset line to the processor receives it.

In the absence of Power_Good, the timer chip holds the reset line on the processor, which prevents the system from running under bad or unstable power conditions. When the timer chip receives the Power_Good signal, it releases the reset and the processor begins executing whatever code is at address FFFF:0000 (usually the ROM BIOS).

If the power supply can't maintain proper outputs (such as when a brownout occurs), the Power_Good signal is withdrawn and the processor is automatically reset. When the power output returns to its proper levels, the power supply regenerates the Power_Good signal and the system again begins operation (as if you had just powered on). By withdrawing Power_Good before the output voltages fall out of regulation, the system never sees the bad power because it is stopped quickly (reset) rather than being allowed to operate using unstable or improper power levels, which can cause memory parity errors and other problems.

Note

You can use the Power_Good feature as a method of implementing a reset switch for the PC. The Power_Good line is wired to the clock generator circuit, which controls the clock and reset lines to the microprocessor. When you ground the Power_Good line with a switch, the timer chip and related circuitry reset the processor. The result is a full hardware reset of the system. Instructions for making and installing a reset switch can be found in the section "Making and Installing a Reset Switch" in the Technical Reference portion of the disc included with this book.

◀◀ See "[Parity and ECC](#)," p. [514](#).

On pre-ATX systems, the Power_Good connection is made via connector P8-1 (P8 pin 1) from the power supply to the motherboard. ATX, BTX, and later systems use pin 8 of the 20/24-pin main power connector, which is usually a gray wire.

A well-designed power supply delays the arrival of the Power_Good signal until all the voltages stabilize after you turn on the system. Badly designed power supplies, which are found in many low-cost systems, often do not delay the Power_Good signal properly and enable the processor to start too soon. (The normal Power_Good delay is 0.10.5 seconds.) Improper Power_Good timing also causes CMOS memory corruption in some systems.

Note

If you find that a system consistently fails to boot up properly the first time you turn on the switch, but that it subsequently boots up if you press the reset or Ctrl+Alt+Delete warm boot command, you likely have a problem with the Power_Good timing. You should install a new, higher-quality power supply and see whether that solves the problem.

Some cheaper power supplies do not have proper Power_Good circuitry and might just tie any +5V line to that signal. Some motherboards are more sensitive to an improperly designed or improperly functioning Power_Good signal than others. Intermittent startup problems are often the result of improper Power_Good signal timing. A common example is when you replace a motherboard in a system and then find that the system intermittently fails to start properly when you turn on the power. This can be very difficult to diagnose, especially for the inexperienced technician, because the problem appears to be caused by the new motherboard. Although it seems as though the new motherboard is defective, it usually turns out that the power supply is poorly designed. It either can't produce stable enough power to properly operate the new board or has an improperly wired or timed Power_Good signal (which is more likely). In these situations, replacing the supply with a higher-quality unit, in addition to the new motherboard, is the proper solution.

Power Supply Form Factors

The shape and general physical layout of a component is called the *form factor*. Items that share a form factor are generally interchangeable, at least as far as their sizes and fits are concerned. When designing a PC, the engineers can choose to use one of the popular standard power supply unit (PSU) form factors, or they can elect to build their own custom design. Choosing the former means that a virtually inexhaustible supply of inexpensive replacement parts will be available in a variety of quality and power output levels. Going the custom route means additional time and expense for development. In addition, the power supply is unique to the system and generally available for replacement only from the original manufacturer. This precludes any upgrades as well, such as installing higher-output replacement models.

If you can't tell already, I am a fan of the industry-standard form factors! Having standards and then following them allows us to upgrade and repair our systems by easily replacing physically (and electrically) interchangeable components. Having interchangeable parts means that we have a better range of choices for replacement items, and the competition makes for better pricing, too.

In the PC market, IBM originally defined the form factor standards and everybody else copied them and this included power supplies. All the popular PC power supply form factors up through 1995 were based on one of three IBM models, including the PC/XT, AT, and PS/2 Model 30. The interesting thing is that these three original IBM power supply form factors all had the same motherboard connectors and pinouts; where they differed was mainly in shape, maximum power output, the number of peripheral power connectors, and switch mounting. PC systems using knock-offs of one of those three designs were popular up through 1996 and beyond; in fact, even the current standard ATX12V models are based on the PS/2 Model 30 physical form factor, but with different connectors.

Intel defined a new power supply form factor in 1995 with the introduction of the ATX form factor. ATX became popular in 1996 and started a shift away from the previous IBM-based standards. ATX and the standards that have followed since use different connectors with additional voltages and signals that allow systems with greater power consumption and additional features that would otherwise not be possible with the AT-style supplies.

Note

Although two power supplies can share the same basic design and form factor, they can differ greatly in quality and efficiency. Later in this chapter, you'll learn about some of the features and specifications to look for when evaluating PC power supplies.

More than 10 different power supply form factors have existed that can be called industry standard. Many of these are or were based on designs IBM created in the 1980s, whereas the rest are based on Intel designs from the 1990s to the present. The industry-standard form factors can be broken down into two main categories: those that are currently in use in modern systems and those that are largely obsolete.

Note that although the names of some of the power supply form factors seem to be the same as those of motherboard form factors, the power supply form factor relates more to the system chassis (case) than to the motherboard. That is because all the form factors use one of only two main types of connector designs: either AT or ATX, with subtle variations on each. So, although a particular power supply form factor might be *typically* associated with a particular motherboard form factor, many other power supplies would plug in

as well.

For example, all modern ATX form factor motherboards with PCI Express slots have two main power connectors, including a 24-pin ATX main connector along with a 4-pin +12V connector. All the modern power supply form factors, including ATX12V, SFX12V, EPS12V, TFX12V, CFX12V, and LFX12V, include these same connectors and therefore plug in to the same motherboard. In other words, no matter what the form factor of the motherboard (ATX, BTX, or any of the smaller variants of either), virtually any of the modern industry-standard power supplies will plug in.

Plugging the power supply connectors into the motherboard is one thing, but for the power supply to work in the system, it must physically fit inside the chassis or case and that is what the different modern power supply form factors are all about. The bottom line is that it is up to you to ensure that the power supply you purchase not only plugs in to your motherboard, but also fits into the chassis or case you plan to use.

[Tables 19.2](#) and [19.3](#) show the industry-standard power supply form factors, their connector types, and the motherboard form factors with which they are *usually* associated.

Table 19.2. Modern Industry-Standard Power Supply Form Factors

Modern Power Supply Form Factors	Year Introduced	Connector Type	Normally Associated Motherboard Form Factors
ATX/ATX12V	1995	20/24-pin ATX/ATX12V	ATX, microATX, BTX, microBTX
SFX/SFX12V/PS3	1997	20/24-pin ATX/ATX12V	microATX, FlexATX, microBTX, picoBTX, Mini-ITX
EPS/EPS12V	1998	24-pin	ATX/ATX12V ATX, extended ATX
TFX12V	2002	20/24-pin	ATX12V microATX, FlexATX, microBTX, picoBTX, Mini-ITX
CFX12V	2003	20/24-pin	ATX12V microBTX, picoBTX
LFX12V	2004	24-pin	ATX12V picoBTX, nanoBTX

SFX12V also includes the PS3 form factor, which is a shortened version of ATX12V.

xxx12V versions include a 4-pin +12V connector.

EPS12V includes an 8-pin +12V connector.

Table 19.3. Obsolete Industry Standard Power Supply Form Factors

Obsolete Power Supply Form Factors	Year Introduced	Connector Type	Normally Associated Motherboard Form Factors
------------------------------------	-----------------	----------------	--

PC/XT	1981	PC/XT	PC/XT, Baby-AT
AT/Desk	1984	AT	Full-size AT, Baby-AT
AT/Tower	1984	AT	Full-size AT, Baby-AT
Baby-AT	1984	AT	Full-size AT, Baby-AT
LPX (PS/2)	1987	AT	Baby-AT, Mini-AT, LPX

PC/XT connectors were the same as AT connectors except one +5V pin (P8 pin 2) was not used.

LPX is also sometimes called PS/2 or Slimline.

Each of these power supply form factors is, or has been, available in numerous configurations and power output levels. The obsolete LPX form factor supply originated in the IBM PS/2 Model 30 in April 1987 and was the standard used on most systems from the late 1980s to mid-1996, when the ATX form factor started to gain in popularity. Since then, ATX and variants of ATX have become by far the dominant form factors for power supplies. It is interesting to note that IBM's legacy lives on even now because ATX, PS3, and EPS are all based on the LPX (PS/2) physical form factor. Any power supply that does not conform to one of these standards is considered *proprietary*. Any systems that use proprietary power supply designs should generally be avoided because replacements are difficult to obtain and upgrades are generally not available. When you consider that the power supply is one of the most failure-prone components, purchasing systems that use proprietary designs can be a significant liability.

◀◀ See "[Motherboard Form Factors](#)," p. [216](#).

Obsolete Form Factors

The following sections explain in detail the form and function of power supply variants that are no longer in use today. Although most users aren't likely to encounter these designs, if you support older PCs, you will.

PC/XT

IBM's PC and XT systems (circa 1981 and 1983, respectively) used the same power supply form factor; the only difference was that the XT supply had more than double the power output capability. Because they were identical in external appearance and the type of connectors they used, you easily could install the higher-output XT supply as an upgrade for a PC system; thus, the idea of upgrading the power supply was born. The tremendous popularity of the original PC and XT systems led several manufacturers to begin building systems that mimicked their shapes and layouts. These *clones* or compatibles, as they have been called, could interchange virtually all components with the IBM systems, including power supplies. Numerous manufacturers then began producing components that followed the form factors used in these systems. The PC/XT power supply and connectors are shown in [Figure 19.1](#). This form factor, however, is considered obsolete.

Figure 19.1. PC/XT form factor power supply.

[\[View full size image\]](#)

Figure 19.2. AT/Desktop form factor power supply.

file:///C:/A/ch19lev1sec3.html (4 of 23)1/1/2006 4:47:07 AM

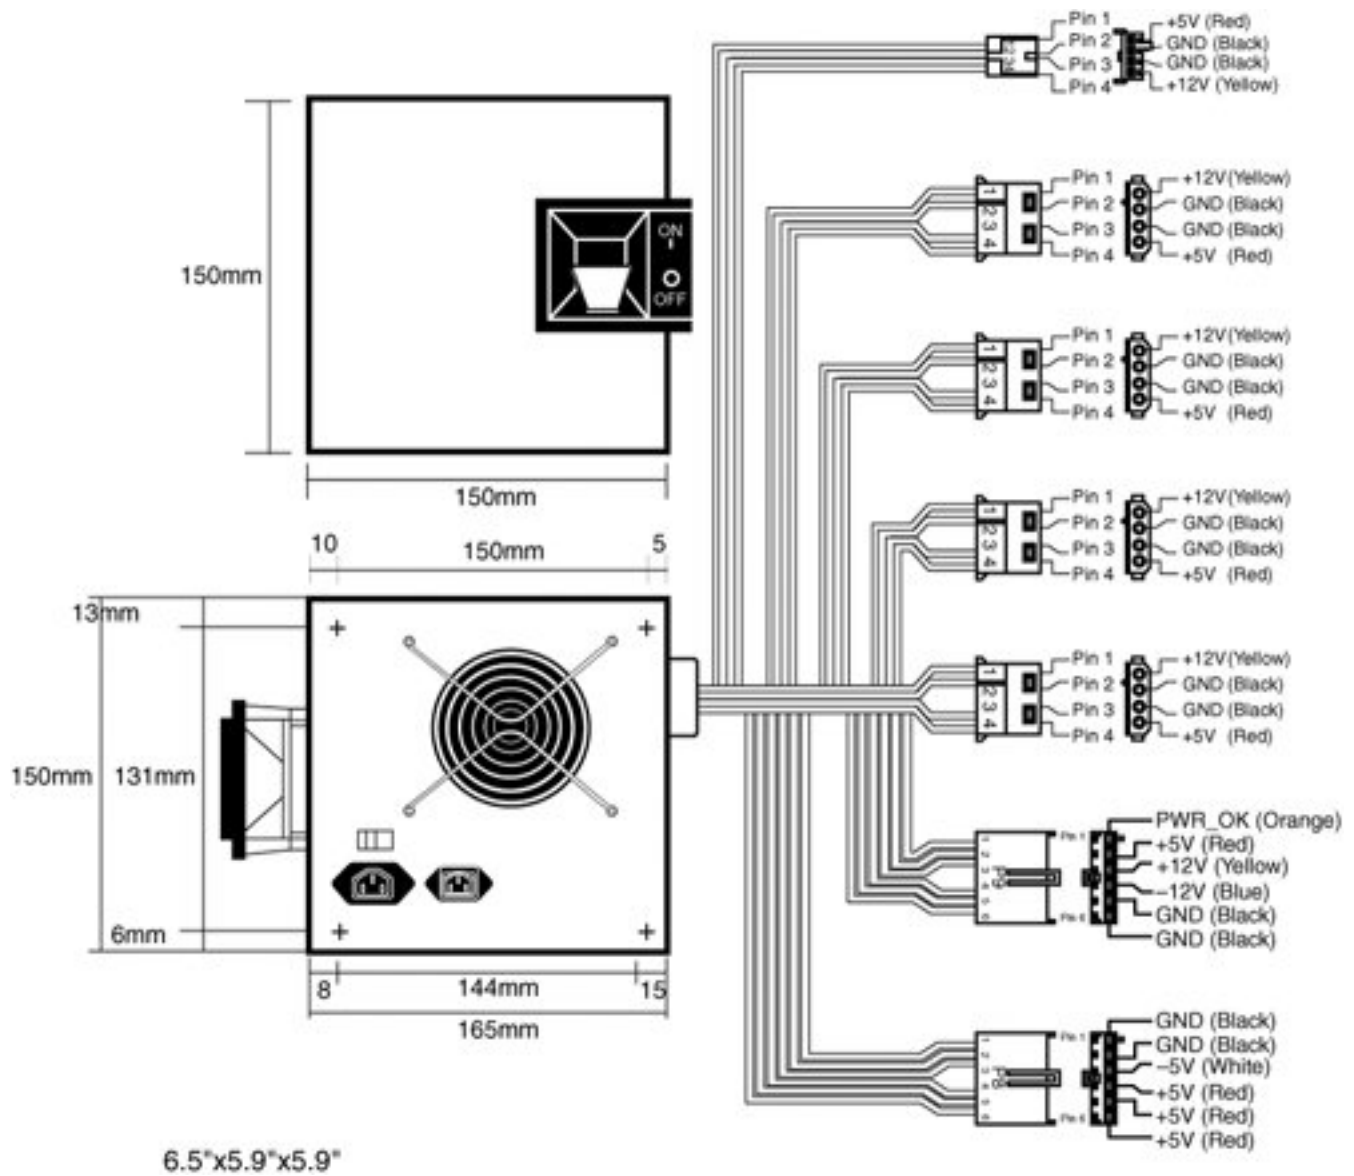

The type of power supply used in most of the AT tower systems was identical to that used in a desktop system, except for the location of the power switch. On the original AT/Desktop systems, the power switch was built in to the side of the power supply (usually in the form of a large toggle switch). AT/Tower systems instead used an external switch attached to the power supply through a four-wire cable. A full-sized AT power supply with a remote switch is called an AT/Tower form factor power supply and is identical to the AT/Desktop supply in size and dimensions. The only difference is the use of an external switch (see [Figure 19.3](#)). This form factor is considered obsolete.

[\[View full size image\]](#)

Figure 19.4. Baby-AT form factor power supply.

[\[View full size image\]](#)

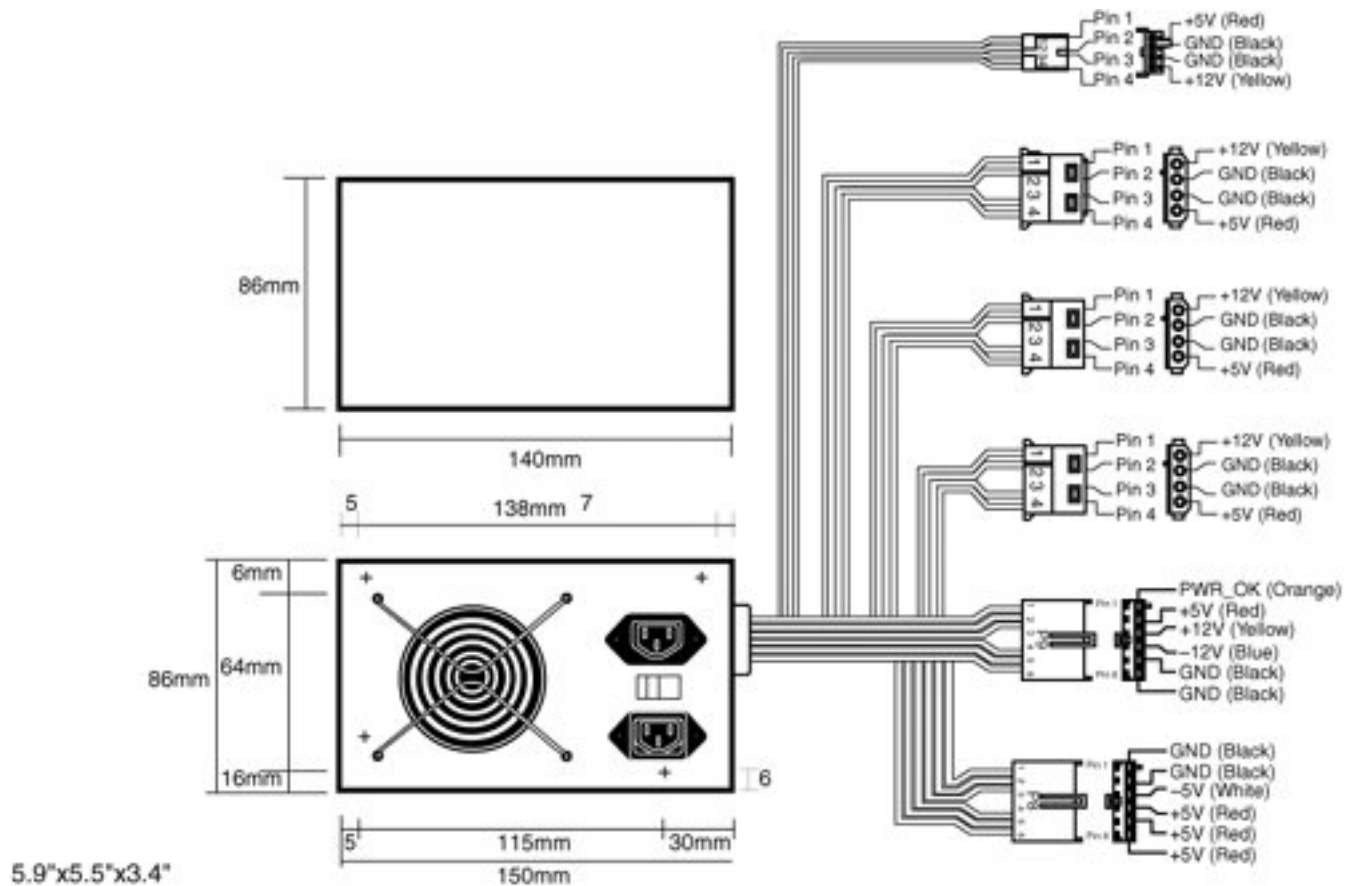

LPX

The next power supply form factor to gain popularity was the LPX style, also called the PS/2 type, Slimline, or slim style (see [Figure 19.5](#)). The PS/2 designation is in reference to the fact that this design originated in the IBM PS/2 Model 30 introduced in April 1987. The LPX-style power supply used the exact same motherboard and disk drive connectors as the previous PC/XT and AT-based standard power supply form factors. LPX power supplies were used primarily in systems with LPX, Baby-AT, or Mini-AT motherboards.

Figure 19.5. LPX form factor power supply.

[\[View full size image\]](#)

The LPX power supply quickly found its way into many manufacturers' systems and soon became a de facto standard. This style of power supply became the staple of the industry for many years, coming in everything from low-profile systems using actual LPX motherboards to desktop or mid-tower systems with Baby-AT or Mini-AT motherboards, as well as full-size towers using Baby-AT or even full-size AT motherboards. Although considered obsolete, the LPX (PS/2) design is still sold today; however, you certainly won't find it in any new PCs. The mechanical form factor lives on, though, because it was the basis for the ATX and PS3 designs that are used in modern systems.

Modern Form Factors

The power supply form factors detailed in the following sections are the standards that continue to be implemented in current systems. ATX is far and away the most common of these, but if you work on a variety of PC types, you are likely to encounter the other types listed here.

ATX/ATX12V

In 1995, Intel saw that the existing power supply designs were literally running out of power. The problem was that the existing standards used two connectors with a total of only 12 pins providing power to the motherboard. In addition, the connectors used were difficult to properly key and plugging them in improperly resulted in short-circuiting and damage to both the motherboard and the power supply. To solve these problems, in 1995 Intel took the existing popular LPX (PS/2) design and simply changed the internal circuitry and connectors (while leaving the mechanical shape the same), giving birth to the ATX power supply form factor (see [Figure 19.6](#)).

Figure 19.6. ATX12V 2.x form factor power supply with 24-pin main, 4-pin

+12V, and optional PCI Express Graphics connectors.

[\[View full size image\]](#)

Intel first released the ATX specification in 1995 and in 1996, it started to become increasingly popular in Pentium and Pentium Probased PCs, capturing 18% of the market within the first year. Since 1996, ATX variants have become both the dominant motherboard and power supply form factors, replacing the

previously popular Baby-AT/LPX designs. ATX12V power supplies are also used with newer motherboard form factors like BTX, ensuring that ATX and its derivatives will remain the most popular power supply form factors for several years to come.

The ATX12V specification defines the physical or mechanical form as well as the electrical connectors for the power supply. From 1995 through early 2000, the ATX power supply form factor was defined as part of the ATX motherboard specification. However, in February 2000, Intel took the power supply specification out of the then-current ATX 2.03 motherboard/chassis specification and created the ATX/ATX12V power supply specification 1.0, adding an optional 4-pin +12V connector at the same time (those with the +12V connector were called ATX12V supplies). The +12V connector was made a requirement in version 1.3 (April 2002), whereupon the specification became only ATX12V. The ATX12V 2.0 specification (February 2003) dropped the 6-pin auxiliary connector, changed the main power connector to 24 pins, and made Serial ATA power connectors a requirement as well. The current version is ATX12V 2.2, which was released in March 2005 and contains only minor changes from the previous releases, such as the use of high current system (HCS) terminals in the connectors.

As the ATX power supply specification has evolved, there have been some changes in the cooling fan orientation and design. The ATX specification originally called for an 80mm fan to be mounted along the inner side of the supply, where it could draw air in from the rear of the chassis and blow it inside across the motherboard. This kind of airflow runs in the opposite direction than most standard supplies, which exhaust air out the back of the supply through a hole in the case where the fan protrudes. The idea was that the reverse-flow design could cool the system more efficiently with only a single fan, eliminating the need for a fan (active) heatsink on the CPU.

Another benefit of the reverse-flow cooling is that the system would run cleaner, freer from dust and dirt. The case would be pressurized, so air would be continuously forced out of the cracks in the case the opposite of what happens with a negative pressure design. For this reason, the reverse-flow cooling design is often referred to as a positive-pressure-ventilation design. On an ATX system with reverse-flow cooling, the air is blown out away from the drive because the only air intake is the single fan vent on the power supply at the rear. For systems that operate in extremely harsh environments, you can add a filter to the fan intake vent to further ensure that all the air entering the system is clean and free of dust.

Although this sounds like a good way to ventilate a system, the positive-pressure design needs to use a more powerful fan to pull the required amount of air through a filter and pressurize the case. Also, if a filter is used, it must be serviced on a periodic basis depending on operating conditions, it could need changing or cleaning as often as every week. In addition, the heat load from the power supply on a fully loaded system heats the air being ingested, blowing warm air over the CPU and reducing the overall cooling capability.

As CPUs evolved to generate more and more heat, the cooling capability of the system became more critical and the positive-pressure design was simply not up to the task. Therefore, subsequent versions of the ATX specification were rewritten to allow both positive- and negative-pressure designs, but they emphasized the standard negative-pressure system with an exhaust fan on the power supply and an additional high-quality cooling fan blowing cool air right on the CPU as the best solution.

Because a standard negative-pressure system offers the greatest cooling capacity for a given fan's airspeed and flow, virtually all the newer ATX-style power supplies use a negative-pressure design, in which air flows out the back of the power supply. Most use an 80mm fan mounted on the rear of the unit blowing outward, but some use an 80mm, a 92mm, or a 120mm fan mounted on the inside upper or lower surface, with open vents on the rear of the system. In either example, the flow of air is such that air is always exhausted out of the system through the rear of the supply.

The ATX power supply form factor addressed several problems with the previous PC/XT, AT, and LPX-type supplies. One is that the power supplies used with PC/XT/AT boards had only two connectors that plugged

in to the motherboard. If you inserted these connectors backward or out of their normal sequence, you would usually fry both the motherboard and the power supply! Most responsible system manufacturers tried to "key" the motherboard and power supply connectors so you couldn't install them backward or out of sequence. However, most vendors of cheaper systems did not feature this keying on the boards or supplies they used. The ATX form factor includes intelligently designed and keyed power plugs to prevent users from incorrectly plugging in their power supplies. The ATX connectors also supply +3.3V, reducing the need for voltage regulators on the motherboard to power +3.3V-based circuits.

Besides the new +3.3V outputs, ATX power supplies furnish another set of outputs that is not typically seen on standard power supplies. The set consists of the Power_On (PS_ON) and 5V_Standby (5VSB) outputs mentioned earlier, known collectively as *Soft Power*. This enables features to be implemented, such as Wake on Ring or Wake on LAN, in which a signal from a modem or network adapter can actually cause a PC to wake up and power on. Many such systems also have the option of setting a wake-up time, at which the PC can automatically turn itself on to perform scheduled tasks. These signals also can enable the optional use of the keyboard to power the system on an option you can set on some systems. These features are possible because the +5V Standby power is always active, giving the motherboard a limited source of power even when off. Check your BIOS Setup for control over these types of features.

SFX/SFX12V

Intel released the smaller microATX motherboard form factor in December 1997, and at the same time also released the SFX (small form factor) power supply design to go with it. Even so, most microATX chassis continued to use the standard ATX power supply instead. Then in March 1999, Intel released the FlexATX addendum to the microATX specification, which was a very small board designed for low-end PCs or PC-based appliances. Since then, the SFX supply has found use in many new compact system designs. Unlike most of the power supply form factor specifications in which a single mechanical or physical outline is defined, the SFX standard actually defines five different physical shapes, some of which are not directly interchangeable. In addition, there have been changes to the connectors required as the specification has evolved. Therefore, when replacing an SFX/SFX12V-type supply, you need to ensure you are purchasing the correct typewhich is to say the type that will physically install in your chassis as well as have the correct connectors for your motherboard.

The number and types of connectors have changed over the life of the specification. The original SFX power supply specification included a single 20-pin motherboard connector. The 4-pin +12V connector to provide independent CPU power was added as an option in the 2.0 revision (May 2001) and was made a requirement in revision 2.3 (April 2003), causing the spec to be renamed as SFX12V in the process. SFX12V version 3.0 changed the main motherboard power connector from 20 pins to 24 pins and made Serial ATA power connectors a requirement as well. The current SFX12V version 3.1 was released in March 2005 and contains a few additional minor revisions, including a change to HCS terminals in the connectors. SFX12V includes several physical designs, including one called the PS3 form factor.

On a standard SFX/SFX12V power supply, a 60mm diameter cooling fan is located inside the power supply housing, facing the inside of the computer's case (see [Figure 19.7](#)). The fan draws the air into the power supply housing from the system cavity and expels it through a port at the rear of the system. Internalizing the fan in this way reduces system noise and results in a standard negative-pressure design. The system can also use additional processor and chassis cooling fans, which are separate from the power supply.

Figure 19.7. SFX/SFX12V standard power supply with internal 60mm fan.

[\[View full size image\]](#)

For systems that require more cooling capability, a version that allows for a larger, 80mm top-mounted cooling fan also is available. The larger fan provides more cooling capability and airflow for systems that need it (see [Figure 19.8](#)).

Figure 19.8. SFX/SFX12V standard power supply with a recessed, top-mounted 80mm fan.

[\[View full size image\]](#)

Another variation of SFX12V also uses a recessed top-mounted 80mm cooling fan, but it has the body of the power supply rotated for greater width but reduced depth, as shown in [Figure 19.9](#).

Figure 19.9. SFX/SFX12V rotated power supply with a recessed top-mounted 80mm fan.

[\[View full size image\]](#)

A special low-profile version of SFX12V designed for a slim chassis is only 50mm tall with an internal 40mm cooling fan, as shown in [Figure 19.10](#).

Figure 19.10. SFX/SFX12V low-profile power supply with internal 40mm fan.

[\[View full size image\]](#)

Finally, a more recent variation on SFX is called the PS3 form factor, defined in Appendix E of the SFX12V specification. Although defined as part of SFX12V, the PS3 form factor is actually a shortened version of ATX12V and is generally used in systems with microATX chassis and motherboards that require higher power output than the smaller SFX variants can supply (see [Figure 19.11](#)).

Figure 19.11. PS3 (SFX/SFX12V) power supply with internal 80mm fan.

[\[View full size image\]](#)

SFX12V power supplies are specifically designed for use in small systems containing a limited amount of hardware and limited upgradability. Most SFX supplies are designed to provide 80300 watts of continuous power in four voltages (+5V, +12V, 12V, and +3.3V). This amount of power has proven to be sufficient for a small system with a processor, an AGP or PCI Express x16 interface, up to four expansion slots, and three peripheral devices such as hard drives and CD-ROMs.

Although Intel designed the SFX12V power supply specification with the microATX and FlexATX motherboard form factors in mind, SFX is a wholly separate standard that is compliant with other motherboards as well. For example, the PS3 variant of SFX12V can be used to replace standard ATX12V power supplies as long as the output capabilities and provided connectors match the system requirements. SFX power supplies use the same 20-pin or 24-pin connectors defined in the ATX/ATX12V standards and include both the Power_On and 5V_Standby outputs. SFX12V power supplies add the 4-pin +12V connector for CPU power, just as ATX12V supplies do. Whether you will use an ATX- or SFX-based power supply in a given system depends more on the case or chassis than the motherboard. Each has the same basic electrical connectors; the main difference is which type of power supply the case is physically designed to accept.

EPS/EPS12V

In 1998, a group of companies including Intel, Hewlett-Packard, NEC, Dell, Data General, Micron, and Compaq created the Server System Infrastructure (SSI), an industry initiative to promote industry-standard form factors covering common server hardware elements such as chassis, power supplies, motherboards, and other components. The idea was to be able to design network servers that could use industry-standard interchangeable parts. You can find out more about SSI at www.ssiforum.org. Although this book does not cover network servers, in many ways a low-end server is a high-end PC, and many high-end components that were once found only on servers have trickled down to standard PCs. This trickle-down theory is especially true when it comes to power supplies.

In 1998, the SSI created the entry-level power supply (EPS) specification, which defines an industry-

standard power supply form factor for entry-level pedestal (standalone tower chassis) servers. The initial EPS standard was based on ATX, but with several enhancements. The first major enhancement was the use of a 24-pin main power connector, which eventually trickled down to the ATX12V as well as other power supply form factor specifications in 2003. EPS also originally called for the use of HCS terminals in the Molex Mini-Fit Jr.-based power supply connectors, which became standard in ATX12V in March 2005 as well. In addition, both the (now-obsolete) auxiliary 6-pin power connector, the 4-pin +12V power connector, and a variation of the 6-pin graphics power connector all appeared in the EPS specifications before ending up in ATX.

The EPS specification originally used a mechanical form factor identical to ATX, but the EPS form factor was later extended to support higher power outputs by allowing the body of the supply to be deeper if necessary. The ATX and the original EPS standards call for a supply that is 86mm tall by 150mm wide by 140mm deep, the same dimensions as the LPX or PS/2 form factors. EPS later added optional extended depths of 180mm and 230mm total. You may think these would require a custom EPS chassis, but in fact many (if not most) full-sized ATX tower chassis can handle these greater depths without interference, especially when using one of the newer breed of shorter-length optical drives (because one or more of the optical drives are often inline with the power supply).

With the improvements in EPS/EPS12V power supplies trickling down to ATX/ATX12V, I have studied the SSI EPS specifications to see what potential improvements might come to ATX. The main difference today between ATX and EPS with respect to connectors is the use of an 8-pin dual +12V connector in EPS12V instead of a 4-pin +12V connector in ATX12V. The 8-pin dual +12V connector is essentially the equivalent of two 4-pin connectors mated together and is used by entry-level servers to power multiple processors. Because of the way the connectors are designed, an 8-pin +12V connector can plug in to a 4-pin +12V connector on a motherboard, with the unused pins simply hanging unused, offset to one side or the other.

The only other major difference between EPS12V and ATX12V is that EPS power supplies can be up to 180mm or 230mm deep, while ATX supplies are technically limited to 140mm depth according to the specification. An example of an EPS12V type supply is the Turbo-Cool 1KW (1-kilowatt) model from PC Power and Cooling (see [Figure 19.12](#)).

Figure 19.12. Turbo-Cool 1KW EPS12V form factor power supply (www.pcpowercooling.com).

This power supply is basically a 230mm deep EPS12V supply that works in place of or as an upgrade to an ATX12V supply as long as the chassis can accommodate the additional depth. EPS12V supplies are

sometimes called *extended ATX* power supplies because of their optional extended length. If you plan on using one of these EPS12V power supplies in a standard ATX chassis, it's important that you measure the available space in your chassis to ensure you have the room behind the supply for the additional depth.

Connector compatibility isn't generally a problem because, by virtue of the Molex Mini-Fit Jr. connector design, you can plug a 24-pin main power connector into a 20-pin socket, as well as an 8-pin dual +12V connector into a 4-pin +12V socket.

If you have the room, an EPS12V power supply can be used with most ATX chassis and motherboards for the ultimate in high-output capabilities.

TFX12V

The TFX12V (thin form factor) power supply was originally introduced by Intel in April 2002 and is designed for small form factor (SFF) systems of about 915 liters in volume, primarily those using low-profile SFF chassis and microATX, FlexATX, or Mini-ITX motherboards. The basic shape of TFX12V is longer and narrower than the ATX- or SFX-based form factors, allowing it to more easily fit into low-profile systems. The dimensions of the TFX12V form factor are shown in [Figure 19.13](#).

Figure 19.13. TFX12V power supply form factor dimensions.

[\[View full size image\]](#)

TFX12V power supplies are designed to deliver nominal power output capabilities of 180300 watts, which is more than adequate for the smaller systems for which they are designed.

TFX12V supplies include a side-mounted internal 80mm fan that is usually thermostatically controlled, so as to run both coolly and quietly. A symmetrically designed mounting system allows the fan to be oriented facing either side inside the system for optimum cooling and flexibility in accommodating different chassis layouts (see [Figure 19.14](#)).

Figure 19.14. TFX12V power supplies are symmetrical and can be mounted with the fan facing either left or right.

Unlike SFX-based supplies, only one standard mechanical form factor exists for TFX12V supplies. TFX12V supplies have also always included the 4-pin +12V connector since the standard appeared in April 2002, well after the +12V connector had been included in other power supply form factors. TFX12V 1.2 (April 2003) added the Serial ATA power connector as an option, while the TFX12V 2.0 release (February 2004) made them mandatory and changed the main power connector from 20 pins to 24 pins. Revision 2.1 (July 2005) includes only minor updates and changes from the previous version.

CFX12V

The CFX12V (compact form factor) power supply was originally introduced by Intel in November 2003 and is designed for mid-sized BTX (balanced technology extended) systems of about 1015 liters in volume, primarily using microBTX or picoBTX motherboards.

CFX12V power supplies are designed to deliver nominal power output capabilities of 220300 watts, which is more than adequate for the mid-sized systems for which they are designed. CFX12V supplies include a rear-mounted internal 80mm fan that is typically thermostatically controlled, so as to run both coolly and quietly. The shape of the supply includes a ledge such that part of the supply can extend over the motherboard, reducing the overall size of the system (see [Figure 19.15](#)). The dimensions of the CFX12V form factor are shown in [Figure 19.16](#).

Figure 19.15. CFX12V power supply.

Figure 19.16. CFX12V power supply dimensions.

[\[View full size image\]](#)

CFX12V supplies have always included the 4-pin +12V connector since the standard first appeared in November 2003, well after the +12V connector had been included in other power supply form factors. TFX12V also included the 24-pin main power connector as well as Serial ATA power connectors as mandatory since its inception. The current CFX12V 1.2 release dates from 2005 and has only minor revisions over previous versions, including a change to HCS terminals in the connectors.

LFX12V

Intel originally introduced the LFX12V (low profile form factor) power supply in April 2004. It's designed for

ultra-small BTX systems of about 69 liters in volume, primarily using picoBTX or nanoBTX motherboards. LFX12V power supplies are designed to deliver nominal power output capabilities of 180-260 watts, which is ideal for the tiny systems for which they are designed. LFX12V supplies include an internal 60mm fan, which is 20mm smaller than that of the CFX12V design. Similar to the CFX12V fan, it is usually thermostatically controlled to ensure quiet operation while still providing adequate cooling. The shape of the supply includes a ledge such that part of the supply can extend over the motherboard, reducing the overall size of the system (see [Figure 19.17](#)). The dimensions of the LFX12V form factor are shown in [Figure 19.18](#).

Figure 19.17. LFX12V power supply.

Figure 19.18. LFX12V power supply dimensions.

All LFX12V supplies include a 24-pin main motherboard power connector, a 4-pin +12V connector, and Serial ATA connectors. The current LFX12V 1.1 release dates from April 2005 and has only minor revisions over the previous version.

Power Switches

Three main types of power switches are used on PCs. They can be described as follows:

- Front panel motherboard-controlled switch (ATX and newer)
- Front panel power supply AC switch (AT/LPX; obsolete)
- Integral power supply AC switch (PC/XT/AT; obsolete)

ATX and Newer

All ATX and newer power supplies that employ the 20- or 24-pin motherboard connector use the PS_ON signal to power up the system. In this design, the power supply runs in standby mode when plugged in with the system off. The PS_ON signal is routed from the power supply through the motherboard to a low-voltage momentary contact DC switch on the front panel. As a result, the remote power switch does not physically control the power supply's access to the 120V AC power, as in older-style power supplies. Instead, the power supply's on or off status is toggled by the PS_ON signal received on the ATX Main power connector. This is sometimes called a *soft-off switch* because this is the name of the (advanced configuration power interface (ACPI) state when the system is off but still receiving standby power.

The PS_ON signal can be manipulated physically by the computer's power switch or electronically by the motherboard under software control. PS_ON is an *active low signal*, meaning the power supply voltage outputs are disabled (the system is off) when the PS_ON is high (greater than or equal to 2.0V). This excludes the +5VSB (Standby) on pin 9 of the ATX main power connector, which is active whenever the power supply is connected to an AC power source. The power supply maintains the PS_ON signal at either 3.3V or +5V. This signal is then routed through the motherboard to the remote switch on the front of the case. When the switch is pressed, the PS_ON signal is grounded. When the power supply sees the PS_ON signal drop to 0.8V or less, the power supply (and system) is turned on. Thus, the remote switch in a system using an ATX or newer power supply carries up to only +5V of DC power, rather than the full 120V/240V AC current like that of the older AT/LPX form factors.

Caution

The continuous presence of the +5VSB power on pin 9 of the ATX main connector means the motherboard is always receiving standby power from the power supply when connected to an AC source, even when the computer is turned off. As a result, it is even more crucial to unplug an ATX system from the power source before working inside the case than it is on an earlier model system.

The remote switch on ATX and newer designs can only put the system in a soft-off state, in which the system appears off but is still receiving standby power. Some ATX and newer power supplies include a hard override AC power switch on the back, which essentially disconnects AC power from the system when turned off. With the AC switch off, the system no longer receives standby power and is essentially the same as being completely unplugged from an AC outlet.

Tip

The design of the ATX power switch is such that the motherboard actually controls the status of the power supply. On systems with full support for ACPI, when you press the power switch, the motherboard informs the OS to perform an orderly shutdown before the power is actually turned off. However, if the system is locked up or corrupted, it can remain running when you press the switch. In that situation, you can manually override the ACPI control by pressing the switch continuously for more than 4 seconds, which overrides the software control and forcibly turns off the system.

PC/XT/AT and LPX Power Switches

The earliest systems had power switches integrated or built directly in to the power supply, which turned the main AC power to the system on and off. This was a simple design, but because the power supply was mounted in the rear right of the system, it required reaching around to the right side near the back of the system to actuate the switch. Also, switching the AC power directly meant the system couldn't be remotely started without special hardware.

Starting in the late '80s, systems with LPX power supplies began using remote front panel switches. These were still AC switches; the only difference was that the AC switch was now mounted remotely (usually on the front panel of the chassis), rather than integrated in the power supply unit. The switch was connected to the power supply via a four-wire cable, and the ends of the cable were fitted with spade connector lugs, which plugged onto the spade connectors on the power switch. The cable from the power supply to the switch in the case contained four color-coded wires. In addition, a fifth wire supplying a ground connection to the case was sometimes included. The switch was usually included with the power supply and heavily shrink-wrapped or insulated where the connector lugs attached, to prevent electric shock.

This solved the ergonomic problem of reaching the switch, but it still didn't enable remote or automated system power-up without special hardware. Plus, you now had a 120V AC switch mounted in the chassis, with wires carrying dangerous voltage through the system. Some of these wires are hot anytime the system is plugged in (all are hot when the system's turned on), creating a dangerous environment for the average person when messing around inside the system.

Caution

At least two of the remote power switch leads to a remote-mounted AC power switch in an AT/LPX supply are energized with 120V AC at all times. You can be electrocuted if you touch the ends of these wires with the power supply plugged in, even if the unit is turned off! For this reason, always make sure the power supply is unplugged before connecting or disconnecting the remote power switch or touching any of the wires connected to it.

The four or five wires are usually color-coded as follows:

- *Brown and blue.* These wires are the live and neutral feed wires from the 120V power cord to the power supply. These are always hot when the power supply is plugged in.
- *Black and white.* These wires carry the AC feed from the switch back to the power supply. These leads should be hot only when the power supply is plugged in and the switch is turned on.

- *Green or green with a yellow stripe.* This is the ground lead. It should be connected to the PC case and should help ground the power supply to the case.

On the switch, the tabs for the leads are usually color-coded; if not, you'll find that most switches have two parallel tabs and two angled tabs. If no color-coding is on the switch, plug the blue and brown wires onto the tabs that are parallel to each other and the black and white wires to the tabs that are angled away from each other. If none of the tabs are angled, simply make sure the blue and brown wires are plugged in to the most closely spaced tabs on one side of the switch and the black and white wires on the most closely spaced tabs on the other side (see [Figure 19.19](#)).

Figure 19.19. Power supply remote pushbutton switch connections.

Caution

Although these wire color-codings and parallel/angled tabs are used on most power supplies, they are not necessarily 100% universal. I have encountered power supplies that do not use the same coloring or tab placement scheme described here. One thing is sure: Two of the wires will be hot with potentially fatal AC voltage anytime the power supply is plugged in. No matter what, always disconnect the power supply from the wall socket before handling any of these wires. Be sure to insulate the connections with electrical tape or heat-shrink tubing so you won't be able to touch the wires when working inside the case in the future.

As long as the blue and brown wires are on one set of tabs and the black and white leads are on the other, the switch and supply will work properly. If you incorrectly mix the leads, you will likely blow the circuit breaker for the wall socket because mixing them can create a direct short circuit.

Motherboard Power Connectors

Every PC power supply has connectors that attach to the motherboard, providing power to the motherboard; processor; memory; chipset; integrated components such as video, LAN, USB, and FireWire; and any cards plugged in to bus slots. These connectors are very important not only are these the main conduit through which power flows to your system, but attaching these connectors improperly can have a devastating effect on your PC, including burning up both your power supply and motherboard. Just as with the mechanical shape of the power supply, these connectors are usually designed to conform to one of several industry-standard specifications, which dictate the types of connectors used as well as the pinouts of the individual wires and terminals. Unfortunately, just as with the mechanical form factors, some PC manufacturers use power supplies with custom connectors or, worse yet, use standard connector types but with modified (incompatible) pinouts (meaning the signals and voltages are rearranged from standard specifications). Plugging a power supply with an incompatible pinout into a motherboard that uses a standard pinout (or vice versa) usually results in the destruction of either the board or the power supply or both.

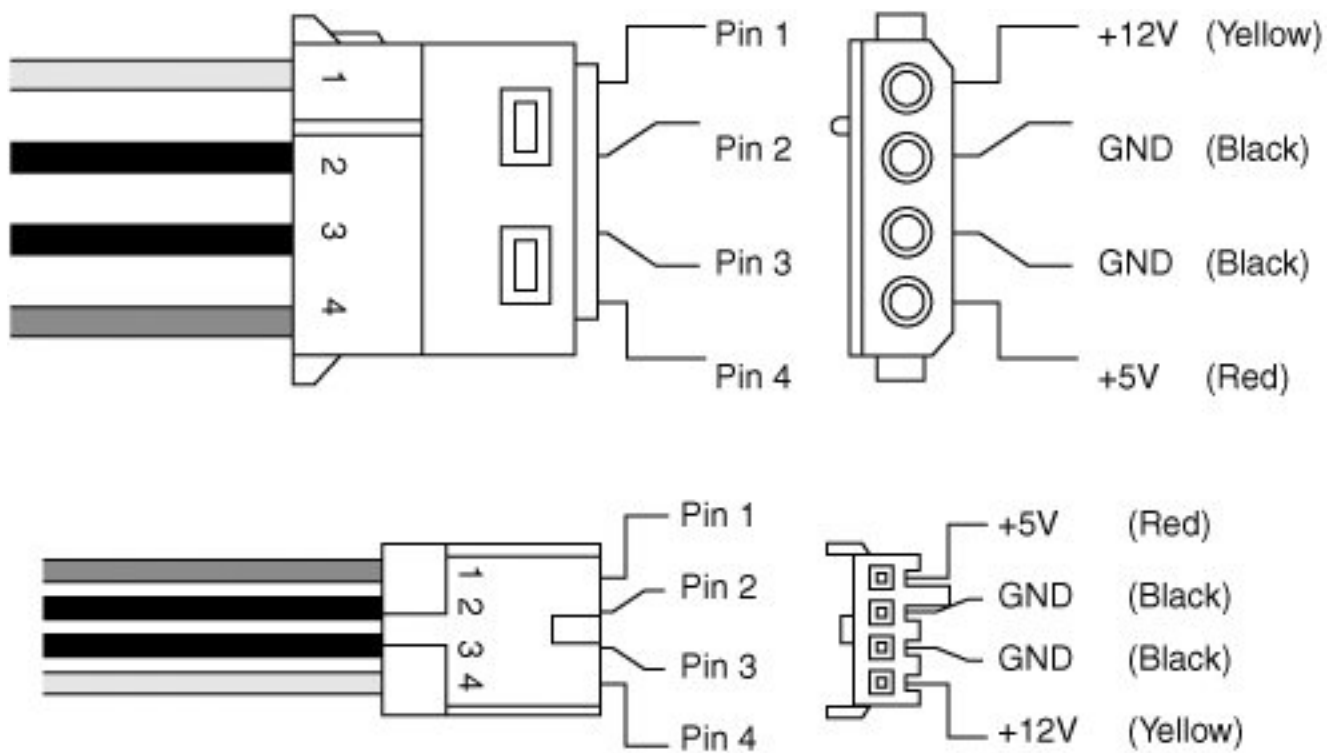

Just as I insist on industry-standard mechanical form factors in my systems, I also want to ensure that they use industry-standard connectors and pinouts. By only purchasing components that conform to industry standards, I can ensure the greatest flexibility and lowest cost for future upgrades and repairs.

Two main sets of motherboard power connectors have been used over the years: what I would call AT/LPX type and the ATX type. Each of these has minor variations; for example, the ATX type has evolved over the years, with new connectors coming (and some going) and modifications to existing connectors. The following sections detail the motherboard power connectors used by various types of industry-standard (and some not-so-standard) power supplies.

AT/LPX Power Supply Connectors

Industry standard PC, XT, AT, Baby-AT, and LPX motherboards all use the same type of main power supply connectors. AT/LPX power supplies feature two main power connectors (P8 and P9), each with six pins that attach the power supply to the motherboard. The terminals used in these connectors are rated to handle up to 5 amps at up to 250V (even though the maximum used in a PC is +12V). These two connectors are shown in [Figure 19.20](#).

Figure 19.20. AT/LPX main P8/P9 (sometimes also called P1/P2) power connectors.

All AT/LPX power supplies that use the P8 and P9 connectors have them installed end to end so that the two black wires (ground connections) on both power connectors are next to each other when properly plugged in. Note the designations "P8" and "P9" are not fully standardized, although most use those designations because that is what IBM stamped on the originals. Some power supplies have them labeled as P1/P2 instead. Because these connectors usually have a clasp that prevents them from being inserted backward on the motherboard's pins, the major concern is getting the two connectors in the correct orientation side by side and also not offsetting by one or more pins side to side. Following the black-to-black rule and ensuring they are on-center keeps you safe. You must take care to ensure that no remaining unconnected motherboard pins exist between or on either side of the two connectors after you install them. A properly installed connector connects to and covers every motherboard power pin. If any power pins are showing on either side of or between the connectors, the entire connector assembly is installed incorrectly, which can result in catastrophic failure for the motherboard and everything plugged in to it at the time of power-up. [Figure 19.21](#) shows the P8 and P9 connectors (sometimes also called P1/P2) in their proper orientation when connecting them to a motherboard.

Figure 19.21. The P8/P9 power connectors (sometimes also called P1/P2) that connect an AT/LPX power supply to the motherboard.

[Table 19.4](#) shows typical AT/LPX power supply connections.

Table 19.4. AT/LPX Power Supply Connectors

Connector	Pin	Signal	Color ^[2]	Connector	Pin	Signal	Color ^[2]
P8 (or P1)	1	Power_Good (+5V)	Orange	P9 (or P2)	1	Ground	Black
	2	+5V ^[1]	Red		2	Ground	Black
	3	+12V	Yellow		3	5V	White
	4	12V	Blue		4	+5V	Red
	5	Ground	Black		5	+5V	Red
	6	Ground	Black		6	+5V	Red

^[2] I have seen some supplies where the manufacturer did not follow industry-standard wire color-codes even though the signals were correct.

^[1] First-generation PC/XT motherboards and power supplies did not require this voltage, so the pin might be missing from the motherboard and terminal and the wire might be missing from the connector (P8 pin 2).

Tip

Although older PC/XT power supplies do not have any connection at connector P8 pin 2, you still can use them on AT-type motherboards, or vice versa. The presence or absence of the +5V on that pin has little or no effect on system operation because the remaining +5V wires can usually carry the load.

Note that all the AT/LPX-type power supplies use the same connectors and pin configurations; there were never any non-standard variations to my knowledge.

ATX and ATX12V 1.x Motherboard Power Connectors

Power supplies conforming to the original ATX and ATX12V 1.x form factor standards or variations thereof use the following three motherboard power connectors:

- 20-pin main power connector
- 6-pin auxiliary power connector
- 4-pin +12V power connector

The main power connector is always required, but the other two are optional depending on the application. Consequently, a given ATX or ATX12V power supply can have up to four different combinations of connectors, as listed here:

- Main power connector only
- Main and auxiliary
- Main and +12V
- Main, auxiliary, and +12V

The most common varieties are those including the main only and those with the main and +12V connectors. Most motherboards that use the +12V connector do not use the auxiliary connector, and vice versa.

20-pin Main Power Connector

The 20-pin main power connector is standard for all power supplies conforming to the ATX and

ATX12V 1.x power supply form factors and consists of a Molex Mini-Fit Jr. connector housing with female terminals. For reference, the connector is Molex part number 39-01-2200 (or equivalent) and the standard terminals are part number 5556 (see [Figure 19.22](#)). This is a 20-pin keyed connector with pins configured as shown in [Table 19.5](#). The colors for the wires listed are those the ATX standard recommends; however, to enable them to vary from manufacturer to manufacturer, they are not required for compliance to the specification. I like to show these connector pinouts in a wire side view, which shows how the pins are arranged looking at the back of the connector (from the wire and not the terminal side). This is because it shows how they would be oriented if you were back-probing the connector with the connector plugged in.

Figure 19.22. ATX-style 20-pin motherboard main power connector, perspective view.

[\[View full size image\]](#)

Table 19.5. ATX Main Power Supply Connector Pinout (Wire Side View)

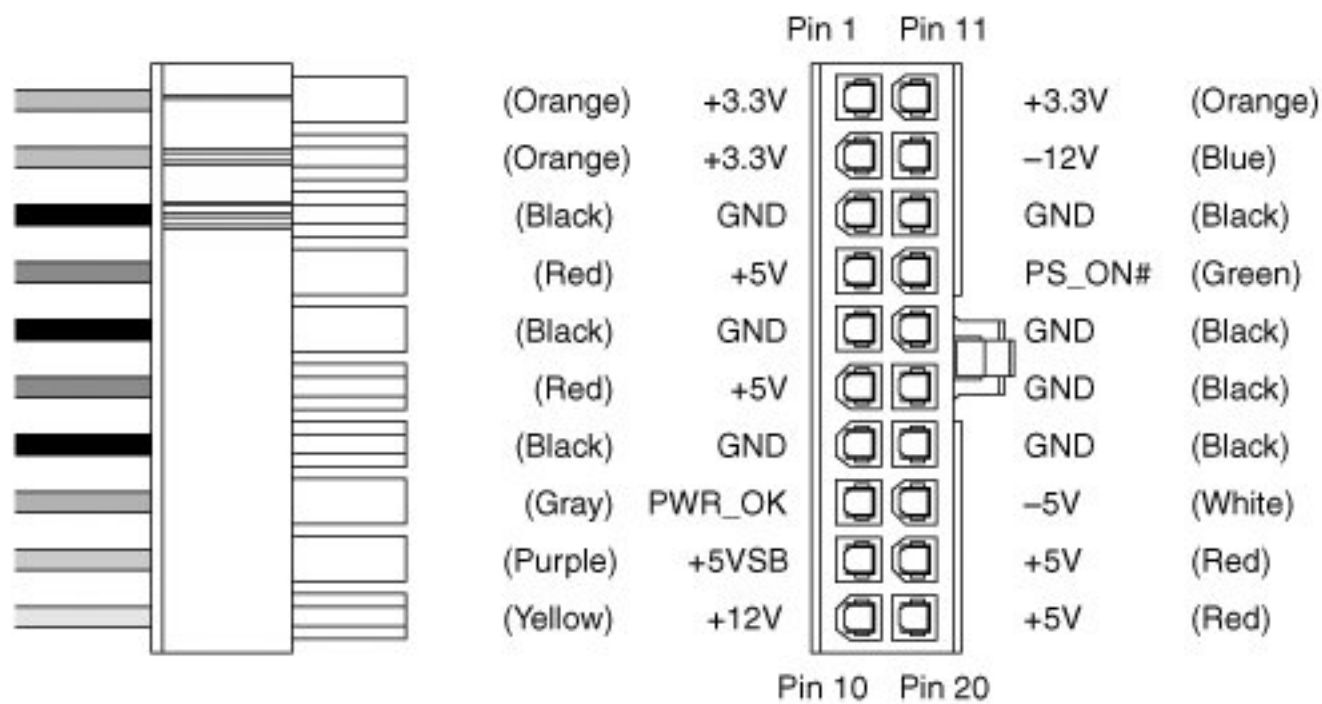

Color	Signal	Pin	Pin	Signal	Color
Orange	+3.3V	11 ^[1]	1	+3.3V	Orange
Blue	12V	12	2	+3.3V	Orange
Black	GND	13	3	GND	Black
Green	PS_On	14	4	+5V	Red
Black	GND	15	5	GND	Black
Black	GND	16	6	+5V	Red
Black	GND	17	7	GND	Black
White	5V	18 ^[2]	8	Power_Good	Gray
Red	+5V	19	9	+5VSB (Standby)	Purple
Red	+5V	20	10	+12V	Yellow

^[1] Might have a second orange or brown wire, used for +3.3V sense feedback used by the power supply to monitor 3.3V regulation.

[2] Pin 18 might be N/C (no connection) on some later model supplies or motherboards because 5V was removed from the ATX12V 1.3 and later specifications. Supplies with no connection at pin 18 should not be used with older motherboards that incorporate ISA Bus slots.

Figure 19.23 shows a view of the connector as if you were looking at it facing the terminal side.

Figure 19.23. ATX/NLX 20-pin main power connector, terminal side view.

Note

The ATX supply features several voltages and signals not seen on earlier AT/LPX designs, such as the +3.3V, PS_On, and +5V_Standby. Therefore, adapting a standard LPX form factor supply to make it work properly in an ATX system is impossible, even though the shapes of the power supplies themselves are virtually identical.

However, because ATX is a superset of the older LPX power supply standard, you can use a connector adapter to allow an ATX power supply to connect to an older motherboard using AT/LPX connectors. PC Power and Cooling (www.pcpowercooling.com) sells this type of adapter.

One of the most important issues with respect to power supply connectors is the capability to deliver sufficient power to the motherboard without overheating. It doesn't help to have a 500-watt power supply if the cable and connector supplying power to the motherboard can handle only 250 watts before they start to melt. When talking about specific connectors, the current rating is stated in amperes per circuit and is a measure of the amount of current that can be passed through a mated terminal that will allow no more than a 30° C (85° F) temperature rise over ambient 22° C (72° F). In other words, at a normal ambient temperature of 30° C (72° F), when run at the maximum rated current, the temperature of the mated terminals will not exceed 52° C (157° F). Because the ambient temperature inside a PC can run 40° C

(104° F) or higher, running power connectors at maximum ratings can result in extremely high temperatures where the connectors are located.

The maximum current level is further de-rated or adjusted for the number of circuits in a given connector housing due to the heat of any adjacent terminals. For example, a power connector might be able to carry 8 amps per circuit in a 4-position connector, but the same connector and terminal design might be able to handle only 6 amps per circuit in a 20-position connector.

All the modern form factor power supplies since ATX have standardized on the use of Molex Mini-Fit Jr. connectors for the main and +12V connectors. A number of connector housings are used with anywhere from 4 to 24 positions or terminals. Molex makes three types of terminals for these connectors: a standard version, an HCS version, and a Plus HCS version. The current ratings for these terminals are shown in [Table 19.6](#).

Table 19.6. Current Ratings for Mini-Fit Jr. Connectors

Mini-Fit Jr. Terminal Type/No.	23 Pins (Amps/ Pin)	46 Pins (Amps/ Pin)	710 Pins (Amps/Pin)	12-24 Pins (Amps/Pin)
Standard/5556	9	8	7	6
HCS/44476	12	11	10	9
Plus HCS/45750	12	12	12	11

All ratings assume Mini-Fit Jr. connectors with 1224 circuits using 18-gauge wire under standard temperature conditions.

The ATX main power connector is either a 20-pin or 24-pin connector, which (if using standard terminals) is rated for up to 6 amps of current per terminal if using the standard terminals. If the connector were upgraded to HCS terminals, the rating would increase to 9 amps per terminal, and if upgraded to Plus HCS terminals, the rating would increase further to 11 amps per terminal. Prior to March 2005, all the power supply form factor specifications called for using standard terminals, but all the ratings from March 2005 to the present have changed to require HCS terminals instead. If your power supply connector has been overheating, you can easily install HCS or Plus HCS terminals to increase the power-handling capability of your connector by 50% or more.

By counting the number of terminals for each voltage level, the power-handling capability of the connector can be calculated as shown in [Table 19.7](#).

Table 19.7. 20-pin Main Power Connector Maximum Power Handling Capabilities

Volts	No. Pins	Using Std. Terminals (W)	Using HCS Terminals (W)	Using Plus HCS Terminals (W)
-------	----------	--------------------------	-------------------------	------------------------------

+3.3V	3	59.4	89.1	108.9
+5V	4	120	180	220
+12V	1	72	108	132
Total watts:		251.4	377.1	460.9

Standard terminals are rated 6 amps.

HCS terminals are rated 9 amps.

Plus HCS terminals are rated 11 amps.

All ratings assume Mini-Fit Jr. connectors with 1224 circuits using 18-gauge wire under standard temperature conditions.

This means the total power-handling capacity of this connector is only 251 watts if using standard terminals, which is lower than many systems need today. Unfortunately, drawing more power than this maximum rating through the connector causes it to overheat. I'm sure you can appreciate how inadequate this has become today; for example, it certainly doesn't make sense to manufacture a 400- or 500-watt power supply if the main power connector can handle only 251 watts without melting! That would be like building a car that could go 200mph and then equipping it with tires rated for only 100mph. Everything would be fine until you exceeded the tires' rated speed, after which the results would not be pretty.

This is why the official power supply form factor specifications were updated in March 2005 to include HCS terminals, which have 50% greater power-handling capability than the standard terminals. Using HCS terminals, the power-handling capability of the 20-pin main connector increases to 377 watts, which is more than most systems need.

6-pin Auxiliary Power Connector

As motherboards and processors have evolved, the need for power has become greater. Each of the terminals in the main power connector are rated for 6 amps (A) using standard terminals, which allows for a maximum supply of approximately 250 watts to the motherboard. Because motherboards with high-speed processors and multiple cards installed could draw more power than that and power supply manufacturers were building supplies with 300-watt and higher ratings, melted connectors were becoming more and more common. The terminals in the main connector overheated under such a load.

To allow for additional power from the supply to the motherboard, Intel modified the ATX specification to add a second auxiliary power connector for high power-drawing ATX motherboards and 250-watt or higher rated supplies. The criteria is such that, if the motherboard could draw more than 18A of +3.3V power and/or more than 24A of +5V power, the auxiliary connector is required to carry the additional load. These higher levels of power are needed in systems using 250- or 300-watt or greater supplies.

The 6-pin auxiliary power connector was added as a safety or stopgap measure in the ATX motherboard 2.02/2.03 and ATX12V 1.x power supply specifications for systems in which the +3.3V and +5V power draw could exceed the respective 18A and 24A maximums allowed using only the main connector with standard terminals. These conditions would normally be met in systems requiring 300W or higher output power supplies. The auxiliary power connector is a 6-pin Molex 90331-0010 connector, which is similar to the motherboard power connectors used on older AT/LPX power supplies for Baby-AT motherboards (see [Figure 19.24](#)).

Figure 19.24. ATX 2.02/2.03 and ATX12V 1.x auxiliary power connector.

The pinouts of the auxiliary connector are shown in [Table 19.8](#).

Table 19.8. ATX Auxiliary Power Connector Pinout

Pin	Signal	Color	Pin	Signal	Color
1	Gnd	Black	4	+3.3V	Orange
2	Gnd	Black	5	+3.3V	Orange
3	Gnd	Black	6	+5V	Red

Each terminal in the auxiliary power connector is rated to handle up to 5 amps of current, slightly less than the main power connector. By counting the number of terminals for each voltage level, the power-handling capability of the connector can be calculated, as shown in [Table 19.9](#).

Table 19.9. 6-pin Auxiliary Power Connector Maximum Power-Handling Capabilities

Volts	No. Pins	Watts
+3.3V	2	33
+5V	1	25
Total watts:		58

Terminals are rated 5 amps.

Ratings assume 18-gauge wire under standard temperature conditions.

This means the total power-handling capacity of this connector is only 58 watts. Drawing more power than this maximum rating through the connector will cause it to overheat.

Combining the 20-pin main plus the auxiliary power connector would result in a maximum power-delivery capability to the motherboard of 309 watts.

Few motherboards actually used this connector, and few power supplies included it. Generally, if a motherboard includes this connector, you need a power supply that has it as well, but if the power supply includes the auxiliary connector but the motherboard does not, it can be left unconnected.

Starting in 2000, both motherboards and power supplies began including a different additional connector that was a better solution than the auxiliary connector. The most recent power supply form factor specifications have removed the auxiliary connector, rendering it an obsolete standard in modern systems.

4-pin +12V Power Connector

Power for the processor comes from a device called the *voltage regulator module (VRM)*, which is built in to most modern motherboards. This device senses the CPU voltage requirements (usually via sense pins on the processor) and calibrates itself to provide the proper voltage to run the CPU. The design of a VRM enables it to run on either +5V or +12V for input power. Many have used +5V over the years, but starting in 2000 most converted to +12V because of the lower current requirements at that voltage. In addition, other devices might have already loaded the +5V, whereas only drive motors typically used the +12V prior to 2000. Whether the VRM on your board uses +5V or +12V depends on the particular motherboard or regulator design. Many modern voltage regulator ICs are designed to run on anything from a +4V to a +36V input, so it is up to the motherboard designer as to how they will be configured.

For example, I studied a system using a First International Computer (FIC) SD-11 motherboard, which used a Semtech SC1144ABCSW voltage regulator. This board design uses the +5V to convert to the lower voltage the CPU needs. Most motherboards use voltage regulator circuits controlled by chips from Semtech (<http://www.semtech.com>) or Linear Technology (<http://www.linear.com>). You can visit their sites for more data on these chips.

That motherboard accepted an Athlon 1GHz Cartridge version (Model 2), which according to AMD has a maximum power draw of 65W and a nominal voltage requirement of 1.8V. 65W at 1.8V would equate to 36.1A of current at that voltage (volts x amps = watts). If the voltage regulator used +5V as a feed, 65W would equate to only 13A at +5V. That would assume 100% efficiency in the regulator, which is impossible. Therefore, assuming 80% efficiency (which is typical), there would be about 16.25A actual draw on the +5V due to the regulator and processor combined.

When you consider that other circuits on the motherboard also use +5V power remember that ISA or PCI cards are drawing that power as well you can see how easy it is to overload the +5V lines from the supply to the motherboard.

Although most motherboard VRM designs up through the Pentium III and Athlon/Duron use +5V-based regulators, most systems since then use +12V-powered regulators. This is because the higher voltage significantly reduces the current draw. Using the same 65W AMD Athlon 1GHz CPU as an example, you would end up with the levels of draw at the various voltages shown in [Table 19.10](#).

Table 19.10. Levels of Draw at Various Voltages

Watts	Volts	Amps	Amps at 80% Regulator Efficiency
65	1.8	36.1	
65	3.3	19.7	24.6
65	5.0	13.0	16.3
65	12.0	5.4	6.8

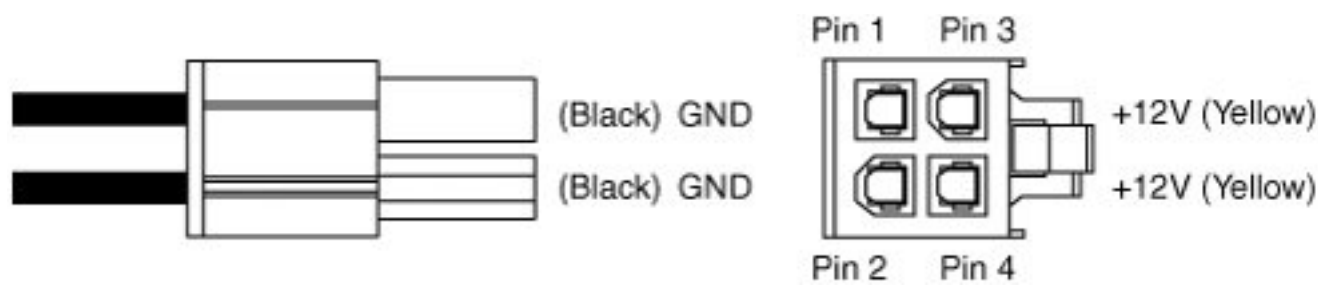

As you can see, using +12V to power the chip results in only 5.4A of draw, or 6.8A assuming 80% efficiency on the part of the regulator.

So, modifying the motherboard VRM circuit to use the +12V power feed would seem simple. Unfortunately, the ATX 2.03 specification has only a single +12V lead in the main power connector. The auxiliary connector has no +12V leads at all, so that is no help. Pulling up to 8A more through a single 18-gauge wire supplying +12V power to the motherboard is a recipe for a melted connector because the contacts in the main ATX connector are rated for only 6A using standard terminals.

To augment the supply of +12V power to the motherboard, Intel created a new ATX12V power supply specification. This added a third power connector, called the +12V connector, specifically to supply additional +12V power to the board. The 4-pin +12V power connector is specified for all power supplies conforming to the ATX12V form factor and consists of a Molex Mini-Fit Jr. connector housing with female terminals. For reference, the connector is Molex part number 39-01-2040 and the terminals are part number 5556. This is the same style of connector as the ATX Main power connector, except with fewer pins.

This connector has two +12V power pins, each rated for 8A total using standard terminals (or up to 11A each using HCS terminals), allowing for up to 16A or more of additional +12V current to the motherboard, for a total of 22A of +12V when combined with the 20-pin main connector. The 4-pin +12V connector is shown in [Figure 19.25](#).

Figure 19.25. A 4-pin +12V power connector.

The pinout of the +12V power connector is shown in [Table 19.11](#).

Table 19.11. +12V Power Connector Pinout (Wire Side View)

Color	Signal	Pin	Pin	Signal	Color
Yellow	+12V	3	1	Gnd	Black
Yellow	+12V	4	2	Gnd	Black

If you are replacing your motherboard with a new one that requires the +12V connection for the CPU voltage regulator, and yet your existing power supply doesn't have that connector, an easy solution is available. Merely convert one of the Peripheral power connectors to a +12V type. PC Power and Cooling has an adapter that can make any standard ATX power supply molex connector into one with a +12V connector. This connector works because the issue is not whether the power supply can generate the necessary +12Vthat has always been available via the Peripheral connectors. The +12V adapter shown in [Figure 19.26](#) solves the connector problem quite nicely.

Figure 19.26. +12V adapter from PC Power and Cooling.

Using standard terminals, each pin in the +12V connector is rated to handle up to 8 amps of current, 11 amps with HCS terminals, or up to 12 amps with Plus HCS terminals. Even though it uses the same design and same terminals as the main power connector, the current rating per terminal is higher on this 4-pin connector than on the 20-pin main because there are fewer terminals overall. By counting the number of terminals for each voltage level, the power-handling capability of the connector can be calculated as shown in [Table 19.12](#).

Table 19.12. 4-pin +12V Power Connector Maximum Power-Handling Capabilities

Volts	No. Pins	Using Std. Terminals (W)	Using HCS Terminals (W)	Using Plus HCS Terminals (W)
-------	----------	--------------------------	-------------------------	------------------------------

+12V 2	192	264	288
--------	-----	-----	-----

Standard terminals are rated 8 amps.

HCS terminals are rated 11 amps.

Plus HCS terminals are rated 12 amps.

All ratings assume Mini-Fit Jr. connectors with 46 circuits using 18-gauge wire under standard temperature conditions.

This means the total power handling capacity of this connector is 192 watts using standard terminals, which is available to and used only by the processor. Drawing more power than this maximum rating through the connector causes it to overheat, unless the HCS or Plus HCS terminals are used.

Combining the 20-pin main plus the 4-pin +12V power connector results in a maximum power-delivery capability to the motherboard of 443 watts (using standard terminals). The important thing to note is that adding the +12V connector provides the capability to support power supplies of up to 500 watts or more without overloading and melting the connectors.

The Reason for Multiple Motherboard Power Connectors

Only the 20-pin main power connector was included in the original ATX specification, and it was sufficient to power PC motherboards and processors in the mid-90s requiring 251 watts or less total power. However, by the late '90s, motherboard and processor power requirements had increased and in some systems the main power connector could no longer shoulder the load. Motherboards and processors that drew more than 251 total watts would potentially overheat the terminals and melt the connector housing, something I witnessed several times myself.

Rather than change the design of the main connector and cause incompatibilities with motherboards that didn't need the additional power, Intel added the auxiliary power connector as a fix to the ATX 2.02 specification in 1998. The auxiliary connector was designed to deliver up to 58 watts of additional +3.3V and +5V power to power-hungry motherboards, which often need the additional power for CPU, memory, and AGP slot voltage regulators. Even though incorporating the additional auxiliary connector was basically a good idea, most motherboards I saw continued to use only the single main power connector, even if it might be overloaded.

Although the auxiliary connector could provide extra +3.3V and +5V power, it did not provide any additional +12V power. The debut of the Pentium 4 processor in 2000 brought even greater power demands from the processor. CPUs run on very low voltages, which are normally provided via voltage regulators on the motherboard. These regulators take in the voltage provided by the power supply and convert it to that required by the processor. Power equals volts times amps. So, for the same power level, the more volts you provide the regulators, the fewer amps they require. Therefore, to reduce the overall current (amps) being delivered to the motherboard, a change was made to the CPU voltage regulators such that they would run on +12V power, instead of the +3.3V or +5V they had been previously using.

This unfortunately created another power problem: Even when combining both the main and auxiliary power connectors, there was only a single +12V terminal supplying up to 6 amps of current to the motherboard. So, to provide additional +12V power and preserve compatibility with the main and auxiliary connectors that had already been defined, in early 2000 Intel added the +12V power connector to the ATX 2.1 specification. This new connector was designed specifically to deliver up to 192 watts of power for the high-output voltage regulators required by the Pentium 4 and newer processors.

Power supplies with the +12V power connector were called *ATX12V supplies*, and a special ATX12V form factor specification was created just for the power supply. Because the +12V power connector was initially used on Pentium 4 motherboards, it became unofficially known as the *P4 connector* even though AMD processor-based motherboards began using it as well. By the end of 2001, most motherboards began requiring this connector and most power supplies being sold for PCs were the ATX12V type.

Because the +12V power connector was designed specifically for the CPU, motherboards incorporating this connector would not run if power was not supplied to it. If you were installing a motherboard that used this connector and your power supply did not feature it as well, you could purchase an adapter that would convert one of the peripheral power connectors (normally used for disk drives) to a +12V power connector. If the power supply had the +12V connector but the motherboard did not, you could leave the +12V connector unplugged.

Because the ATX12V standard includes the same main and auxiliary connectors as had previously been defined, an ATX12V power supply was fully backward compatible with ATX and could be used to replace a regular ATX type. If a motherboard did not require the extra +12V or auxiliary connectors, they could simply remain unplugged inside the case.

As a consequence of changing the CPU voltage regulators on the motherboard to use +12V power, the load on the +3.3V and +5V rails was reduced such that the auxiliary connector was no longer necessary; consequently, many ATX12V supplies came without it. The auxiliary connector was officially removed from the ATX12V 2.0 specification in 2000. Some ATX12V power supplies still continue to include the auxiliary power connector, and of course you should be sure it is present if required by your motherboard.

Because of the way the auxiliary and +12V connectors were added to the design, newer power supplies were almost always interchangeable with those in older systems. In fact, one of the greatest things about the ATX and ATX12V standards is that, aside from a few anomalies (such as certain proprietary Dell systems made in the late '90s with nonstandard power connector pinouts), most ATX12V power supplies will work in most PCs built from 1996 up to the present.

Unfortunately, recent changes in motherboard and power supply form factors might mean that compatible power supply connections can't be taken for granted any longer. The recent changes in power supply form factors mostly relate to newer motherboards, processors, and even video cards requiring ever-increasing amounts of power.

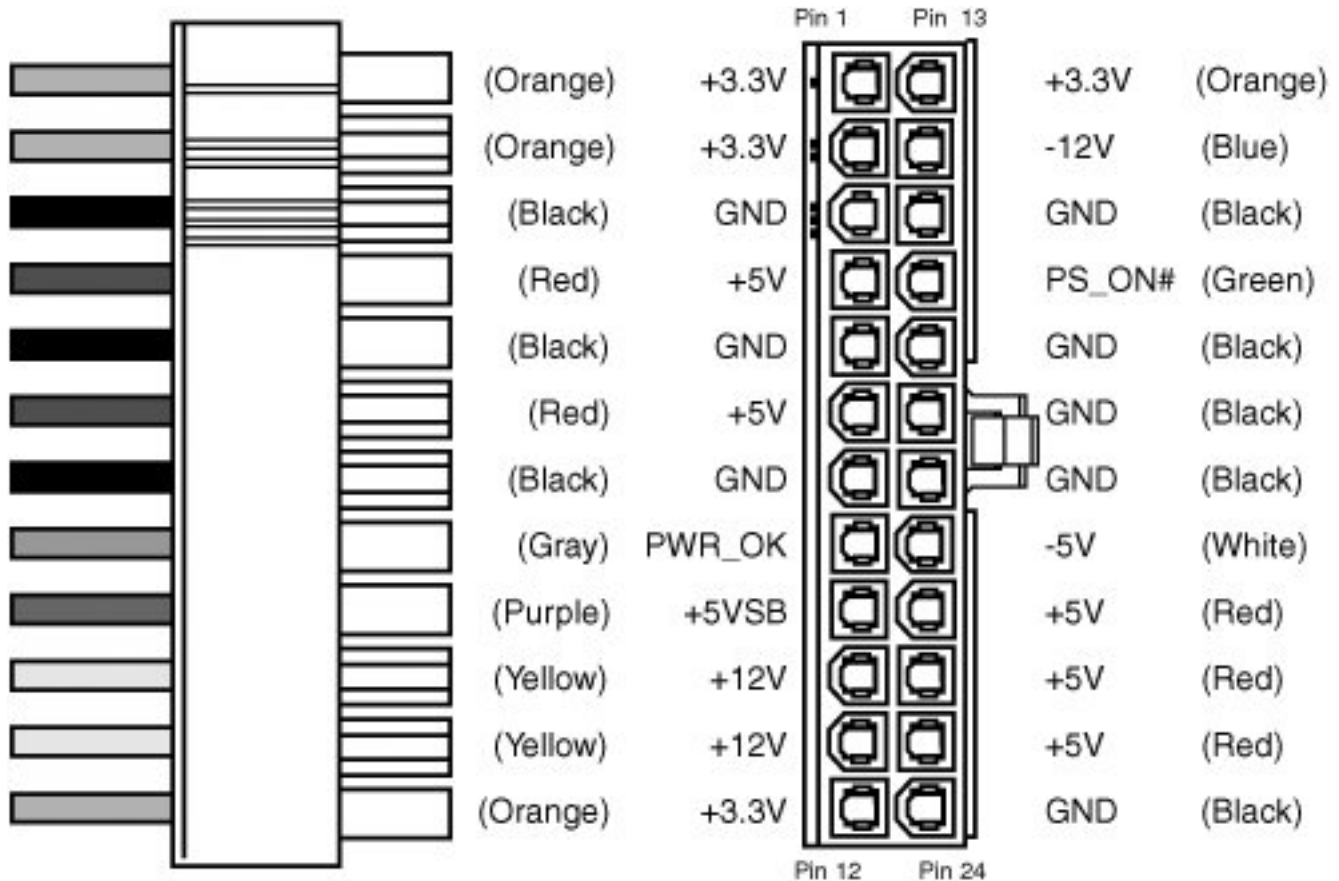

ATX12V 2.x 24-pin Main Power Connector

Starting in June 2004, the new PCI Express bus first appeared on motherboards. PCI Express is a type of serial bus with standard slots having a single channel or lane of communications. These single-lane slots are called *x1 slots* and are designed for peripheral cards such as network cards, sound cards, and the like. PCI Express also includes a special higher-bandwidth slot with 16 lanes (called an *x16 slot*), which is especially designed for use by video cards. During development it was realized that PCI Express x16 video cards could draw more power than what was allowed by the existing 20-pin main and 6-pin auxiliary power supply connectors, especially when it came to +12V power.

The problem was that the 20-pin main connector had only a single +12V pin and the new video cards required more +12V power than a single pin could safely deliver. The +12V connector that had already been added was specifically for the CPU and was unavailable to other devices. Rather than add another supplemental or auxiliary connector as it had done before, Intel eventually decided that it was finally time to upgrade the main power connector to supply more power.

The result was officially called ATX12V 2.0 and was released in February 2003. ATX12V 2.0 included two major changes from the previous ATX12V 1.x specifications. This included a new 24-pin main power connector and the elimination of the 6-pin auxiliary power connector. The new 24-pin main power connector included 4 more pins supplying additional +3.3V, +5V, and +12V power plus a ground. The inclusion of these extra pins not only satisfied the power requirements for PCI Express video cards drawing up to 75 watts, but also made the older 6-pin auxiliary connector unnecessary. The pinout of the new 24-pin main power connector started to be implemented in motherboards in mid-2004 (see [Figure 19.27](#)).

Figure 19.27. ATX12V 2.x 24-pin main power connector.

ATX12V 2.x Main Power Connector

When looking at this image, it's important to keep in mind that pin 13 might have a second orange or brown wire for +3.3V sense feedback, used by the power supply to monitor 3.3V regulation. Also, pin 20 might be N/C (no connection) because 5V was removed from the ATX12V 2.01 and later specifications. Supplies with no connection at pin 20 should not be used with older motherboards that incorporate ISA Bus slots.

It is interesting to note that the 24-pin connector is not really that new; it first appeared in the Server System Infrastructure (SSI) Entry Power Supply (EPS) specification released in 1998. SSI (www.ssiforum.org) is an initiative designed to create standard interfaces for server components, including power supplies. The 24-pin main power connector was first created for servers because, at the time, only servers needed the additional power. Today's PCs draw the same power levels as servers did years ago, so rather than reinvent an incompatible connector, the ATX12V 2.0 standard merely incorporated the 24-pin connector already specified in the SSI EPS standard.

Compared to the previous 20-pin design, the 24-pin main power connector includes additional +3.3V, +5V, and +12V terminals allowing a substantially greater amount of power to be delivered to the motherboard. Each terminal in the main power connector is rated to handle up to 6 amps of current. By counting the number of terminals for each voltage level, the power-handling capability of the connector can be calculated as shown in [Table 19.13](#).

Table 19.13. 24-pin Main Power Connector Maximum Power-Handling Capabilities

Volts	No. Pins	Using Std. Terminals (W)	Using HCS Terminals (W)	Using Plus HCS Terminals (W)
+3.3V	4	79.2	118.8	145.2
+5V	5	150	225	275
+12V	2	144	216	264
Total watts:		373.2	559.8	684.2

Standard terminals are rated 6 amps.

HCS terminals are rated 9 amps.

Plus HCS terminals are rated 11 amps.

All ratings assume Mini-Fit Jr. connectors with 1224 circuits using 18-gauge wire under standard temperature conditions.

This means the total power-handling capacity of this connector is 373 watts using standard terminals or 560 watts using HCS terminals, which is substantially higher than the 251 watts available in the previous 20-pin connector. Combining the 24-pin main and the 4-pin +12V power connector results in up to 565 watts (standard terminals) or 824 watts (using HCS terminals) total power available to the motherboard and processor! This is more than enough to support the highest-output power supplies on the market today, despite the fact that the power supply also has to supply power to the various disk drives in the system.

Backward and Forward Compatibility

If you have reached this point, I'm sure you have some questions. For example, what happens if you purchase a new power supply that has a 24-pin main power connector but your motherboard has only a 20-pin main power socket? Likewise, what if you purchase a new motherboard that has a 24-pin main power socket but your power supply has only a 20-pin main power connector? The answers to these questions are surprising to say the least.

First, let me say that there are adapters that can convert a 24-pin connector to a 20-pin type, and the other way around, but surprisingly these adapters are *not* usually necessary, or even desirable. The plain truth is that compatibility has been engineered into the connectors, power supplies, and motherboards from the start.

If you look at the 24-pin main power connector diagram and compare it to the previous 20-pin design, you'll see that the extra 4 pins are all placed on one end of the connector and all the other pins are defined the same as they were previously. The design of these connectors is such that it allows an interesting bit of backward compatibility. The result is that you can plug a 24-pin main connector directly into a motherboard that has a 20-pin socket (and vice versa), without using an adapter! The trick is to position the connector such that the 4 extra pins are empty. Depending on the latch design, the latch on the side might not engage, but the connector will otherwise plug in and operate properly.

[Figure 19.28](#) shows how you would connect a new power supply with a 24-pin connector to a motherboard that has only a 20-pin socket. The terminals on the 24-pin connector that are highlighted in gray would plug directly into the 20-pin socket, while the white highlighted terminals would remain free and unconnected.

Figure 19.28. Connecting a 24-pin main power connector to a 20-pin motherboard socket.

Logically this works because the first 20 pins of the 24-pin connector that match the 20-pin motherboard socket contain the correct signals in the correct positions. The only problem that might arise is if there were some component on the motherboard directly adjacent to the end of the 20-pin power socket that would physically interfere with the four extra unused terminals on the 24-pin connector.

What about the opposite condition, in which you have a new motherboard with a 24-pin socket but your power supply has only a 20-pin connector? In this case, four terminals at the end of the motherboard socket are not connected. This also works because the 20-pin portion of both the connector and socket are the same. But this example raises another question: Will the motherboard operate properly without the extra power pins? Because the extra signals are merely additional voltage pins that are already present in the remaining part of the connector, the answer should be yes, but if the motherboard draws a lot of power, it can overload the remaining pins. After all, preventing overloads is the reason the extra pins were added in the first place.

Fortunately, even that problem has been solved. All the motherboards I've seen that use a 24-pin main power connector also have an additional peripheral (that is, disk drive) power connector onboard designed to provide the extra power that would be missing if you connected a 20-pin main power connector from your power supply. The documentation for the motherboard refers to this as an *alternate power connector*. [Figure 19.29](#) shows an Intel D925XBC motherboard, which features 24-pin main, 4-pin +12V, and 4-pin alternate power connectors.

Figure 19.29. Intel D925XBC motherboard power connectors.

Regardless of whether you connect a 20- or 24-pin connector, the +12V power connector is always required because it provides power to the CPU. If you also plug a 24-pin main power connector into the 24-pin socket on the motherboard, the alternate power connection is unnecessary. However, you can plug a 20-pin main power connector into the 24-pin main power socket on the motherboard and then simply select a spare peripheral (disk drive) power connector from the power supply and plug it into the alternate power connector. Most power supplies have several extra peripheral power connectors for supporting additional drives. Using a 20-pin main and the alternate power connector satisfies the power requirements for the motherboard and any PCI Express x16 video cards, which can then draw up to 75 watts.

As a side note, you should be careful when plugging in the mismatched connectors so that they are offset properly. The main, +12V, and PCI Express graphics connectors are Molex Mini-Fit Jr. type connectors that are keyed by virtue of a series of differently shaped plastic protrusions used around the terminals, which fit similarly shaped holes in the mating connectors. This keying is designed to prevent backward or improper off-center insertion, but I have found two problems with the keying that should be noted. One is that some alternate low-quality connector brands are built to looser tolerances than the original high-quality Molex versions, and the sloppier fit of the low-quality versions sometimes allows improper insertion. The other problem is that, with sufficient force, the keying on even the high-quality versions can be overcome.

Because plugging a 20-pin connector into a 24-pin socket or a 24-pin connector into a 20-pin socket is designed to work even though they don't fully match up, you need to make sure you have the offsets correct or you risk damaging the board when you power it up.

Dell Proprietary (Nonstandard) ATX Design

If you currently own a desktop system made between 1996 and 2000 from Dell, you will definitely want to pay attention to this section. A potential booby trap is waiting to nail the unsuspecting owners of these systems who decide to upgrade either the motherboard or power supply. This hidden trap can cause the destruction of the motherboard, power supply, or both! Okay, now that I have your attention, read on....

As those of you who have attended my seminars or read previous editions of this book will know, I have long been a promoter of industry-standard components and wouldn't think of purchasing a desktop PC that didn't have what I consider an industry-standard form factor motherboard, power supply, and chassis (ATX, for example). I've been down the proprietary road before with systems from Packard Bell, Compaq, IBM, and other companies that used custom, unique, or proprietary components. For example, during a momentary lapse of reason in the early '90s, I purchased a Packard Bell system. I quickly outgrew the capabilities of the system, so I thought I'd upgrade it with a new motherboard and a faster processor. It was then that I discovered, to my horror, that LPX systems were not an interchangeable standard. Because of riser card differences, virtually no interchangeability of motherboards, riser cards, chassis, and power supplies existed. I had what I now refer to as a "disposable PC" the kind you can't upgrade and have to throw away instead. Suddenly, the money I thought I had saved when initially purchasing the system paled in comparison to what I'd now have to spend to completely replace it. Lesson learned.

After several upgrade and repair experiences like that, I decided never again would I be trapped by systems using proprietary or nonstandard components. By purchasing only systems built with industry-standard parts, I could easily and inexpensively upgrade, maintain, or repair the systems for many years into the future. I have been preaching the gospel of industry-standard components in my seminars and in this book ever since.

Of course, building your own system from scratch is one way to avoid proprietary components, but often that route is more costly in both time and money than purchasing a prebuilt system. And what systems should I recommend for people who want an inexpensive prebuilt system but one that uses industry-standard parts so it can be inexpensively upgraded and repaired later? Although many system vendors and assemblers exist, I've settled on companies such as Gateway, MPC (formerly MicronPC), and Dell. In fact, those are really the three largest system vendors that deal direct, and they mostly sell systems that use industry-standard ATX form factor components in all their main desktop system product lines. Or so I thought.

It seems that when Dell converted to the ATX motherboard form factor in mid-1996, it unfortunately defected from the newly released standard and began using specially modified Intel-supplied ATX motherboards with custom-wired power connectors. Inevitably, it also had custom power supplies made that duplicated the nonstandard pinout of the motherboard power connectors.

An even bigger crime than simply using nonstandard power connectors is that only the pinout is nonstandard; the connectors look like and are keyed the same as is dictated by true ATX. Therefore, nothing prevents you from plugging the Dell nonstandard power supply into a new industry-standard ATX motherboard you installed in your Dell case as an upgrade, or even plugging a new upgraded industry-standard ATX power supply into your existing Dell motherboard. But mixing either a new ATX board with the Dell supply or a new ATX supply with the existing Dell board is a recipe for silicon toast. How do you like your fried chips: medium or well-done?

Frankly, I'm amazed I haven't heard more about this because Dell has climbed to the lead in worldwide PC sales. In any case, I figure by getting this information out I can save thousands of innocent motherboards and power supplies from instant death upon installation.

If you've already fallen victim to this nasty circumstance, believe me, I feel your pain. I discovered this the hard way as wellby frying parts. At first, I thought the upgraded power supply I installed in one of my Dell systems was bad, especially considering the dramatic way it smoked when I turned on the system: I actually saw fire through the vents! Good thing I decided to check the color codes on the connectors and verify the pinout on another Dell system by using a voltmeter before I installed and fried a second supply. I was lucky in that the smoked supply didn't take the motherboard with it; I can only surmise that the supply fried so quickly it sacrificed itself and saved the motherboard. You might not be so lucky, and in most cases I'd expect you'd fry the board and supply together.

Call me a fool, but I didn't think I'd have to check the color-coding or get out my voltmeter to verify the Dell "pseudo-ATX" power connector pinouts before I installed a new ATX supply or motherboard. You'll also find that motherboard and power supply manufacturers don't like to replace these items under warranty when they are fried in this manner due to nonstandard connector wiring.

Dell's official explanation for its lack of conformance to the ATX standard was, "In the mid-90s the industry moved to a higher use of 3.3V motherboard components. Dell engineers designed a connector that supported the increased use of 3.3V current which differed from the industry proposed designs that we deemed less than robust." Unfortunately, this explanation doesn't hold much water because the standard ATX connector incorporated three 3.3V pins, allowing for up to 18A of current and the addition of the Auxiliary Connector added two more pins with 10A of additional current. Dell's pseudo-ATX design had only three 3.3V pins in the Auxiliary Connector, which could supply only up to 15A to the board. You can see that even the main ATX Connector alone had more 3.3V current than Dell's design using two connectors!

Because its technical explanation fails to address the issue, the only other reason I can imagine it did this is to lock people into purchasing replacement motherboards or power supplies from Dell. What makes this worse is that Dell uses virtually all Intel-manufactured boards in its systems. One system I have uses an Intel D815EEA motherboard, which is the same board used by many of the other major system builders, including Gateway and Micron. It's the same, except for the power connectors, that is. The difference is that Dell has Intel custom make the boards for Dell with the nonstandard connectors. Everybody else gets virtually the same Intel boards, but with industry-standard connectors.

[Tables 19.14](#) and [19.15](#) show the nonstandard Dell main and auxiliary power supply connections. This nonstandard wiring is used on Dell's pseudo-ATX systems.

Table 19.14. Dell Proprietary (Nonstandard) 20-pin ATX Main Power Connector Pinout (Wire Side View)

Color	Signal	Pin	Pin	Signal	Color
Gray	PS_On	11	1	+5V	Red
Black	Gnd	12	2	Gnd	Black
Black	Gnd	13	3	+5V	Red

Black	Gnd	14	4	Gnd	Black
White	5V	15	5	Power_Good	Orange
Red	+5V	16	6	+5VSB	(Standby) Purple
Red	+5V	17	7	+12V	Yellow
Red	+5V	18	8	12V	Blue
KEY (blank)		19	9	Gnd	Black
Red	+5V	20	10	Gnd	Black

Table 19.15. Dell Proprietary (Nonstandard) ATX Auxiliary Power Connector Pinout

Pin	Signal	Color	Pin	Signal	Color
1	Gnd	Black	4	+3.3	Blue/White
2	Gnd	Black	5	+3.3	Blue/White
3	Gnd	Black	6	+3.3	Blue/White

At first I thought that if all Dell did was switch some of the terminals around, I could use a terminal pick to remove the terminals from the connectors (with the wires attached) and merely reinsert them into the proper connector positions, enabling me to use the Dell power supply with an upgraded ATX motherboard in the future. Unfortunately, if you study the Dell main and auxiliary connector pinouts I've listed here and compare them to the industry-standard ATX pinouts listed earlier, you'll see that not only are the voltage and signal positions changed, but the number of terminals carrying specific voltages and grounds has changed as well. You could modify a Dell supply to work with a standard ATX board or modify a standard ATX supply to work with a Dell board, but you'd have to do some cutting and splicing in addition to swapping some terminals around. Usually, it isn't worth the time and effort.

If you do decide to upgrade the motherboard in any Dell system purchased between 1996 and 2000, a simple solution is availablejust be sure you replace both the motherboard *and* power supply with industry-standard ATX components at the same time. That way nothing gets fried, and you'll be back to having a true industry-standard ATX system. If you want to replace just the Dell motherboard, you're out of luck unless you get your replacement board from Dell. On the other hand, if you want to replace just the power supply, you do have one alternative. PC Power and Cooling now makes several high-performance replacement power supplies with the modified Dell wiring. The internals are identical to its industry-standard, high-performance ATX suppliesonly the number and arrangement of wires have changed.

Fortunately, starting in 2000, Dell switched to using industry-standard ATX power connections in its Dimension 4300, 4400, 8200, and newer systems. That means barring any other unforeseen glitches, these systems should be more easily upgradeable by just replacing either the power supply or the motherboard alone.

Unfortunately, some of the newer Dell XPS systems use power supplies with proprietary mechanical form factors, which prevents you from installing an industry-standard replacement supply in the future. The bottom line is that, no matter which system you purchase, I recommend you check that it uses a power supply with an industry-standard form factor, both in regards to the electrical connectors and the physical shape.

Additional Power Connectors

Besides the motherboard power connectors, all power supplies include a variety of additional power connectors, mainly used for internally mounted drives but usable by other components as well. Most of these connectors are industry-standard types required by the various power supply form factor specifications. The following sections discuss the various types of additional device power connectors you're likely to find in your PC.

Peripheral Power Connectors

Perhaps the most common additional power connector seen on power supplies is the *peripheral power connector*, also called the *disk drive power connector*. What we know as the peripheral power connector was originally created by AMP as part of the commercial MATE-N-LOK series.

To determine the location of pin 1, carefully look at the connector. It is usually embossed in the plastic connector body; however, it is often tiny and difficult to read. Fortunately, these connectors are keyed and therefore difficult to insert incorrectly. [Figure 19.30](#) shows the keying with respect to pin numbers on the larger drive power connector.

Figure 19.30. A peripheral power connector.

This is the one connector type that has been on all PC power supplies from the original IBM PC to the latest systems built today. It is most commonly known as a disk drive connector, but it is also used in some systems to provide additional power to the motherboard, video card, cooling fans, or just about anything that can use +5V or +12V power.

A peripheral power connector is a 4-pin connector with round terminals spaced 0.200" apart, rated to carry up to 11 amps per pin. Because there is one +12V pin and one +5V pin (the other two are grounds), the maximum power-handling capability of the peripheral connector is 187 watts. The plug is 0.830" wide, making it suitable for larger drives and devices.

[Table 19.16](#) shows the peripheral power connector pinout and wire colors.

Table 19.16.
Peripheral
Power
Connector
Pinout (Large
Drive Power
Connector)

Pin	Signal	Color
1	+12V	Yellow
2	Gnd	Black
3	Gnd	Black
4	+5V	Red

Floppy Power Connectors

When 3 1/2" floppy drives were first being integrated into PCs in the mid-1980s, it was clear that a smaller power connector was necessary. The answer came in what is now known as the *floppy power connector*, which was created by AMP as part of the EI (economy interconnection) series. These connectors are now used on all types of smaller drives and devices and feature the same +12V, +5V, and ground pins as the larger peripheral power connector. The floppy power connector has 4 pins spaced 2.5mm (0.098") apart, which makes the entire connector about half the overall width as the larger peripheral power connector. The pins are rated for only 2 amps each, giving a maximum power-handling capability of 34 watts.

[Table 19.17](#) shows the pinouts for the smaller floppy drive power connector.

Table 19.17. 3
1/2" Floppy

**Power
Connector
Pinout (Small
Drive Power
Connector)**

Pin Signal Color

1	+5V	Red
2	Gnd	Black
3	Gnd	Black
4	+12V	Yellow

The peripheral and floppy power connectors are universal with regard to pin configuration and even wire color. [Figure 19.31](#) shows the peripheral and floppy power connectors.

Figure 19.31. Peripheral and floppy power connectors.

The pin numbering and voltage designations are reversed on the floppy power connector. Be careful if you are making or using an adapter cable from one type of connector to another. Reversing the red and yellow wires will fry the drive or device you plug in to.

Early power supplies featured only two peripheral power connectors, whereas later power supplies featured

four or more of the larger peripheral (disk drive) connectors and one or two of the smaller floppy power connectors. Depending on their power ratings and intended uses, some supplies have as many as eight or more peripheral and/or floppy power connectors.

If you are adding drives and need additional power connectors, Y splitter cables (see [Figure 19.32](#)) as well as peripheral-to-floppy power connector adapters (see [Figure 19.33](#)) are available from many electronics supply houses (including RadioShack). These cables can adapt a single power connector to service two drives or enable you to convert the large peripheral power connector to a smaller floppy drive power connector. If you are using several Y-adapters, be sure that your total power supply output is capable of supplying the additional power and that you don't draw more power than a single connector can handle.

Figure 19.32. A common Y-adapter power cable.

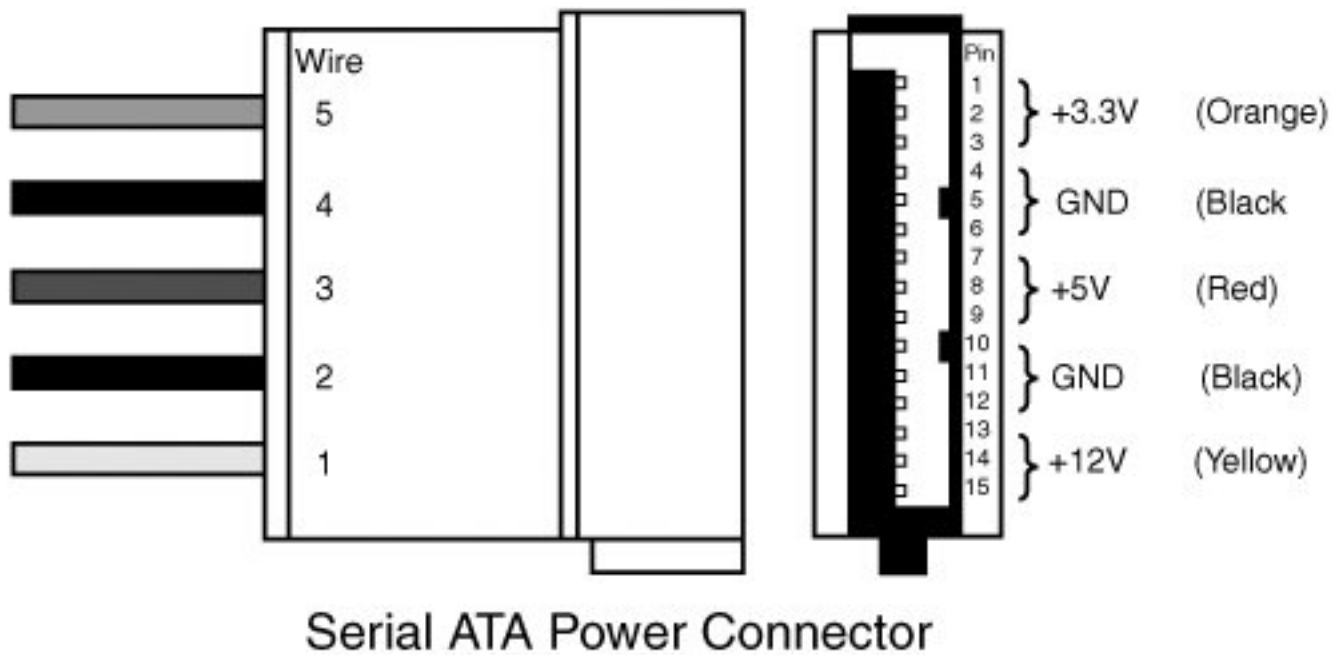

Figure 19.33. A peripheral-to-floppy power adapter cable.

Serial ATA Power Connectors

If you want to add Serial ATA drives to an existing system, you will need a newer power supply that includes a Serial ATA (SATA) power connector. The SATA power connector is a special 15-pin connector fed by only five wires, meaning 3 pins are connected directly to each wire. The overall width is about the same as the peripheral power connector, but the SATA connector is significantly thinner. All the most recent power supply form factor specifications include SATA power connectors as mandatory for systems supporting SATA drives. [Figure 19.34](#) shows a Serial ATA power connector.

Figure 19.34. A Serial ATA power connector.

In the SATA power connector, each wire is connected to three terminal pins and the wire numbering is not in sync with the terminal numbering, which can be confusing.

If your power supply does not feature SATA power connectors, you can use an adapter to convert a standard peripheral power connector to a SATA power connector. However, such adapters do not include the +3.3V power. Fortunately, though, this is not a problem for most uses because most drives do not require +3.3V and use only +12V and +5V instead.

[Figure 19.35](#) shows a peripheral-to-SATA power connector adapter.

Figure 19.35. A peripheral-to-SATA power adapter.

PCI Express x16 Graphics Power Connectors (SLI)

Although the ATX12V 2.x specification includes a new 24-pin main power connector with more power for devices such as video cards, the design was intended to power a video card drawing up to 75 watts

maximum. There are already some video cards on the market drawing more power than that; for example, NVIDIA's GeForce 6800 Ultra draws 110 watts and future cards might draw even more power. Greater than 75 watts cannot be provided via the motherboard directly, so the PCI-SIG (Special Interest Group) developed a standard for supplying at least 150 watts of power directly to the video card from the power supply via an additional graphics power connector. This will likely be included in future ATX12V power supply standards as well.

The PCI Express x16 Graphics Power specification consists of a 6-pin Molex Mini-Fit Jr. connector housing with female terminals that is used to provide power directly to the video card. For reference, the connector is Molex part number 39-01-2060 and the terminals are part number 5556 (standard terminals). This is the same style of connector as the main and +12V power connectors. The pinout of the connector is shown in [Figure 19.36](#).

Figure 19.36. PCI Express x16 Graphics 150W power connector.

PCI Express x16 Graphics 150W-ATX Connector

Pin 2 is technically listed as "not connected" in the specification. Most graphics cards don't use it, but most power supplies do seem to include +12V there.

Each pin in the PCI Express graphics power connector is rated to handle up to 8 amps of current using standard terminals or 11 amps using HCS terminals. By counting the number of terminals for each voltage level, the power-handling capability of the connector can be calculated (see [Table 19.18](#)).

Table 19.18. PCI Express x16 Graphics 150W Power Connector Maximum Power-Handling Capabilities

Volts	No. Pins	Using Std. Terminals (W)	Using HCS Terminals (W)	Using Plus HCS Terminals (W)
+12V	2	192	264	288

Only two +12V pins are in the official standard, even though most power supplies include three.

Standard terminals are rated 8 amps.

HCS terminals are rated 11 amps.

Plus HCS terminals are rated 12 amps.

All ratings assume Mini-Fit Jr. connectors with 46 circuits using 18-gauge wire under standard temperature conditions.

Even though the specification calls for a delivery capability of only 150 watts, the total power-handling capacity of this connector is actually 192 watts using standard terminals, or 264 watts using HCS terminals. This should be more than enough for even the most power-hungry video cards in the future.

These connectors are often called SLI connectors because they are used by high-end PCI Express x16 boards with SLI capabilities. SLI is NVIDIA's method of using two video cards in unison, with each one drawing half of the screen for twice the performance. Each card can draw upwards of 150 watts, so most power supplies that are rated as SLI-ready include two of the 6-pin PCI Express x16 150W graphics power connectors. Using two video cards drawing 110 watts each means that, even if you have a 500-watt power supply, you will need only 280 watts of power to run the motherboard and all the disk drives. Systems using dual SLI video cards require the highest-output supplies available, and some of the current ones are capable of putting out up to 1,000 watts (1 kilowatt) or more.

Note

NVIDIA has trademarked the term *SLI* as meaning *scalable link interface*, but its primary competitor AT also uses similar dual-graphics card technology called CrossFire to achieve similar performance improvements.

If your existing power supply doesn't feature a PCI Express x16 Graphics power connector, you can use a Y-adaptor to convert two peripheral power connectors into a single 6-pin PCI Express x16 power connector.

Power Supply Specifications

Power supplies have several specifications that define their input and output capabilities as well as their operational characteristics. The following sections define and examine most of the common specifications related to power supplies.

Power Supply Loading

PC power supplies are of a *switching* rather than a *linear* design. The switching type of design uses a high-speed oscillator circuit to convert the higher wall-socket AC voltage to the much lower DC voltage used to power the PC and PC components. Switching-type power supplies are noted for being very efficient in size, weight, and energy in comparison to the linear design, which uses a large internal transformer to generate various outputs. This type of transformer-based design is inefficient in at least three ways. First, the output voltage of the transformer linearly follows the input voltage (hence the name *linear*), so any fluctuations in the AC power going into the system can cause problems with the output. Second, the high current-level (power) requirements of a PC system require the use of heavy wiring in the transformer. Third, the 60Hz frequency of the AC power supplied from your building is difficult to filter out inside the power supply, requiring large and expensive filter capacitors and rectifiers.

The switching supply, on the other hand, uses a switching circuit that chops up the incoming power at a relatively high frequency. This enables the use of high-frequency transformers that are much smaller and lighter. Also, the higher frequency is much easier and cheaper to filter out at the output, and the input voltage can vary widely. Input ranging from 90V to 135V still produces the proper output levels, and many switching supplies can automatically adjust to 240V input.

One characteristic of all switching-type power supplies is that they do not run without a *load*. Therefore, you must have something such as a motherboard and hard drive plugged in and drawing power for the supply to work. If you simply have the power supply on a bench with nothing plugged in to it, either the supply burns up or its protection circuitry shuts it down. Most power supplies are protected from no-load operation and shut down automatically. Some of the cheapest supplies, however, lack the protection circuit and relay and can be destroyed after a few seconds of no-load operation. A few power supplies have their own built-in load resistors, so they can run even though there isn't a normal load (such as a motherboard or hard disk) plugged in.

Some power supplies have minimum load requirements for both the +5V and +12V sides. According to IBM specifications for the 192-watt power supply used in the original AT, a minimum load of 7.0 amps was required at +5V and a minimum of 2.5 amps was required at +12V for the supply to work properly. As long as a motherboard was plugged in to the power supply, the motherboard would draw sufficient +5V at all times to keep those circuits in the supply happy. However, +12V is typically used only by motors (and not motherboards), and the floppy or CD/DVD drive motors are off most of the time. Because floppy or optical (CD/DVD) drives don't present any +12V load unless they are spinning, systems without a hard disk drive could have problems because there wouldn't be enough load on the +12V circuit in the supply.

To alleviate problems, when IBM used to ship the original AT systems without a hard disk, it plugged the hard disk drive power cable into a large 5-ohm, 50-watt sandbar resistor that was mounted in a small, metal cage assembly where the drive would have been. The AT case had screw holes on top of where the hard disk would go, specifically designed to mount this resistor cage.

Note

Several computer stores I knew of in the mid-1980s ordered the diskless AT and installed their own 20MB or 30MB drives, which they could get more cheaply from sources other than IBM. They were throwing away the load resistors by the hundreds! I managed to grab a couple at the time, which is how I know the type of resistor they used.

This resistor would be connected between pin 1 (+12V) and pin 2 (Ground) on the hard disk power connector. This placed a 2.4-amp load on the supply's +12V output, drawing 28.8 watts of power (it would get hot!) and thus enabling the supply to operate normally. Note that the cooling fan in most power supplies draws approximately 0.10.25 amps, bringing the total load to 2.5 amps or more. If the load resistor were missing, the system would intermittently fail to start up.

Most of the power supplies in use today do not require as much of a load as the original IBM AT power supply. In most cases, a minimum load of 00.3 amps at +3.3V, 2.04.0 amps at +5V, and 0.51.0 amps at +12V is considered acceptable. Most motherboards easily draw the minimum +5V current by themselves. The standard power supply cooling fan draws only 0.10.25 amps, so the +12V minimum load might still be a problem for a diskless workstation. Generally, the higher the rating on the supply, the more minimum load required. However, exceptions do exist, so this is a specification you should check when evaluating power supplies.

Some switching power supplies have built-in load resistors and can run in a no-load situation. Most power supplies don't have internal load resistors but might require only a small load on the +5V line to operate properly. Some supplies, however, might require +3.3V, +5V, and +12V loads to work the only way to know is by checking the documentation for the particular supply in question.

No matter what, if you want to properly and accurately bench test a power supply, be sure you place a load on at least one (or preferably all) of the positive voltage outputs. This is one reason it is best to test a supply while it is installed in the system, instead of testing it separately on the bench. For impromptu bench testing, you can use a spare motherboard and one or more hard disk drives to load the outputs.

Power Supply Ratings

A system manufacturer should be able to provide you the technical specifications of the power supplies it uses in its systems. This type of information can be found in the system's technical reference manual, as well as on stickers attached directly to the power supply. Power supply manufacturers can also supply this data, which is preferable if you can identify the manufacturer and contact them directly or via the Web.

The input specifications are listed as voltages, and the output specifications are listed as amps at several voltage levels. IBM reports output wattage level as "specified output wattage." If your manufacturer does not list the total wattage, you can convert amperage to wattage by using the following simple formula:

watts = volts x amps

For example, if a motherboard is listed as drawing 6 amps of +5V current, that equals 30 watts of power according to the formula.

By multiplying the voltage by the amperage available at each main output and then adding the results, you can calculate the total capable output wattage of the supply. Note that only positive voltage outputs are normally used in calculating outputs; the negative outputs, Standby, Power_Good, or other signals that are not used to power components are exempt.

[Table 19.19](#) shows the standard power supply output levels available in industry-standard form factors. Most manufacturers offer supplies with ratings from 100 watts to 450 watts or more. [Table 19.20](#) shows the rated outputs at each of the voltage levels for supplies with different manufacturer-specified output ratings. To compile the table, I referred to the specification sheets for supplies from Astec Power (note that they no longer make PC power supplies) and PC Power and Cooling. Although most of the ratings are fairly accurate, there appears to be overly optimistic rounding going on in some of the ratings.

Table 19.19. Typical Non-ATX Power Supply Output Ratings

Rated Output (Watts)	100W	150W	200W	250W	300W	375W	450W
Output current (amps):							
+5V	10.0	15.0	20.0	25.0	32.0	35.0	45.0
+12V	3.5	5.5	8.0	10.0	10.0	13.0	15.0
5V	0.3	0.3	0.3	0.5	0.5	0.5	1.0
12V	0.3	0.3	0.3	0.5	0.5	0.5	1.0
Calc. output (watts)	92	141	196	245	280	331	405

Adding a +3.3V output to the power supply modifies the equation significantly. [Table 19.20](#) contains data for various ATX/ATX12V power supplies from PC Power and Cooling.

Table 19.20. PC Power and Cooling ATX/ATX12V Power Supply Output Ratings

Model (Rated Output)	235W	250W	275W	300W	350W	400W	425W	510W
+3.3V	13	13	14	14	28	40	40	30
+5V	22	25	30	30	32	40	40	40
+12V	8	10	10	12	15	15	15	34
5V	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3
12V	0.5	0.5	1.0	1.0	0.8	1.0	1.0	2.0
+5VSB	2.0	2.0	2.0	2.0	2.0	2.0	2.0	3.0

Total watts (3.3+5+12)^[*]249288316340432512512707

+3.3V and +5V Max.125150150150215300300300

The 400W and 425W supplies listed here seem to have the same specs; however, the 400W version uses a special low-speed quiet fan that has slightly less cooling ability, hence the lower maximum rating figure.

[*] Note the calculated maximum output is theoretical, assuming the maximum draw from the +3.3V, +5V, and +12V simultaneously. Virtually all power supplies place limits on the maximum combined draw for the +3.3V and +5V combined. This would make the true maximum rating somewhat less than the calculated maximum shown here.

If you compute the total output using the formula described earlier, these power supplies seem to produce an output that is much higher than their ratings. The 300W model, for example, comes out at 340 watts. However, notice that the supply also has a maximum combined output for the +3.3V and +5V of 150 watts. This means you can't draw the maximum rating on both the +5V and +3.3V circuits simultaneously but must keep the total combined draw between them at 150W or less. This brings the total output to a more logical 294 watts.

Most PC power supplies have ratings between 150 and 300 watts. Although lesser ratings are not usually desirable, you can purchase heavy-duty power supplies for most systems that have outputs as high as 600 watts or more.

The 300-watt and larger units are recommended for fully optioned desktops or tower systems. These supplies run any combination of motherboard and expansion card, as well as a large number of disk drives and other peripherals. In most cases, you can't exceed the ratings on these power supplies the system will run out of room for additional items first!

Most power supplies are considered to be universal, or worldwide. That is, they also can run on the 240V, 50-cycle current used in Europe and many other parts of the world. Many power supplies that can switch from 120V to 240V input do so automatically, but a few require you to set a switch on the back of the power supply to indicate which type of power you will access.

Note

In North America, power companies are required to supply split-phase 240V (plus or minus 5%) AC, which equals two 120V legs. Resistive voltage drops in the building wiring can cause the 240V to drop to 220V or the 120V to drop to 110V by the time the power reaches an outlet at the end of a long circuit run. For this reason, the input voltage for an AC-powered device might be listed as anything between 220V and 240V, or 110V and 120V. I use the 240/120V numbers throughout this chapter because that is the intended standard figure.

Caution

If your supply does not switch input voltages automatically, make sure the voltage setting is correct. If you plug the power supply into a 120V outlet while it's set in the 240V setting, no damage will result, but the supply won't operate properly until you correct the setting. On the

other hand, if you plug in to a 240V outlet and have the switch set for 120V, you can cause damage.

Other Power Supply Specifications

In addition to power output, many other specifications and features go into making a high-quality power supply. I have had many systems over the years. My experience has been that if a brownout occurs in a room with several systems running, the systems with higher-quality power supplies and higher output ratings are far more likely to make it through the power disturbances unscathed, whereas others choke.

High-quality power supplies also help protect your systems. A high-quality power supply from a vendor such as PC Power and Cooling will not be damaged if any of the following conditions occur:

- A 100% power outage of any duration
- A brownout of any kind
- A spike of up to 2,500V applied directly to the AC input (for example, a lightning strike or a lightning simulation test)

Decent power supplies have an extremely low current leakage to ground of less than 500 microamps. This safety feature is important if your outlet has a missing or an improperly wired ground line.

As you can see, these specifications are fairly tough and are certainly representative of a high-quality power supply. Make sure that your supply can meet these specifications.

You can also use many other criteria to evaluate a power supply. The power supply is a component many users ignore when shopping for a PC, and it is therefore one that some system vendors choose to skimp on. After all, a dealer is far more likely to be able to increase the price of a computer by spending money on additional memory or a larger hard drive than by installing a better power supply.

When buying a computer (or a replacement power supply), you always should learn as much as possible about the power supply. However, many consumers are intimidated by the vocabulary and statistics found in a typical power supply specification. Here are some of the most common parameters found on power supply specification sheets, along with their meanings:

- *Mean Time Between Failures (MTBF) or Mean Time To Failure (MTTF)*. The (calculated) average interval, in hours, that the power supply is expected to operate before failing. Power supplies typically have MTBF ratings (such as 100,000 hours or more) that are clearly not the result of real-time empirical testing. In fact, manufacturers use published standards to calculate the results based on the failure rates of the power supply's individual components. MTBF figures for power supplies often include the load to which the power supply was subjected (in the form of a percentage) and the temperature of the environment in which the tests were performed.
- *Input Range (or Operating Range)*. The range of voltages that the power supply is prepared to accept from the AC power source. For 120V AC power, an input range of 90V135V is common; for 240V power, a 180V270V range is typical.
- *Peak Inrush Current*. The greatest amount of current drawn by the power supply at a given moment immediately after it is turned on, expressed in terms of amps at a particular voltage. The lower the current, the less thermal shock the system experiences.
- *Hold-up Time*. The amount of time (in milliseconds) that a power supply can maintain output within the specified voltage ranges after a loss of input power. This enables your PC to continue running

without resetting or rebooting if a brief interruption in AC power occurs. Values of 1530 milliseconds are common for today's power supplies, and the higher (longer), the better. The ATX12V specification calls for a minimum of 17ms hold-up time.

- *Transient Response.* The amount of time (in microseconds) a power supply takes to bring its output back to the specified voltage ranges after a steep change in the output current. In other words, the amount of time it takes for the output power levels to stabilize after a device in the system starts or stops drawing power. Power supplies sample the current being used by the computer at regular intervals. When a device stops drawing power during one of these intervals (such as when a floppy drive stops spinning), the power supply might supply too high a voltage to the output for a brief time. This excess voltage is called *overshoot*, and the transient response is the time that it takes for the voltage to return to the specified level. This is seen as a spike in voltage by the system and can cause glitches and lockups. Once a major problem that came with switching power supplies, overshoot has been greatly reduced in recent years. Transient response values are sometimes expressed in time intervals, and at other times they are expressed in terms of a particular output change, such as "power output levels stay within regulation during output changes of up to 20%."
- *Overvoltage Protection.* Defines the trip points for each output at which the power supply shuts down or squelches that output. Values can be expressed as a percentage (for example, 120% for +3.3 and +5V) or as raw voltages (for example, +4.6V for the +3.3V output and +7.0V for the +5V output).
- *Maximum Load Current.* The largest amount of current (in amps) that safely can be delivered through a particular output. Values are expressed as individual amperages for each output voltage. With these figures, you can calculate not only the total amount of power the power supply can supply, but also how many devices using those various voltages it can support.
- *Minimum Load Current.* The smallest amount of current (in amps) that must be drawn from a particular output for that output to function. If the current drawn from an output falls below the minimum, the power supply could be damaged or automatically shut down.
- *Load Regulation (or Voltage Load Regulation).* When the current drawn from a particular output increases or decreases, the voltage changes slightly as well—usually increasing as the current rises. Load regulation is the change in the voltage for a particular output as it transitions from its minimum load to its maximum load (or vice versa). Values, expressed in terms of a +/-percentage, typically range from +/-1% to +/-5% for the +3.3V, +5V, and +12V outputs.
- *Line Regulation.* The change in output voltage as the AC input voltage transitions from the lowest to the highest value of the input range. A power supply should be capable of handling any AC voltage in its input range with a change in its output of 1% or less.
- *Efficiency.* The ratio of power input to power output, expressed in terms of a percentage. Values of 65%–85% are common for power supplies today. The remaining 15%–35% of the power input is converted to heat during the AC/DC conversion process. Although greater efficiency means less heat inside the computer (always a good thing) and lower electric bills, it should not be emphasized at the expense of precision, stability, and durability, as evidenced in the supply's load regulation and other parameters.
- *Ripple (or Ripple and Noise, or AC Ripple, or PARD [Periodic and Random Deviation]).* The average voltage of all AC effects on the power supply outputs, usually measured in millivolts peak-to-peak or as a percentage of the nominal output voltage. The lower this figure, the better. Higher-quality units are typically rated at 1% ripple (or less), which if expressed in volts would be 1% of the output. Consequently, for +5V that would be 0.05V or 50mV (millivolts). Ripple can be caused by internal switching transients, feed through of the rectified line frequency, and other random noise.

Power Factor Correction

Recently, the power line efficiency and harmonic distortion generation of PC power supplies has come under examination. This generally falls under the topic of the power factor of the supply. Interest in power factor is not only due to an improvement in power efficiency, but also because of a reduction in the generation of harmonics back on the power line. In particular, new standards are now mandatory in many European Union (EU) countries that require harmonics be reduced below a specific amount. The circuitry required to do this is called *power factor correction (PFC)*.

The *power factor* measures how effectively electrical power is being used and is expressed as a number between 0 and 1. A high power factor means that electrical power is being used effectively, whereas a low power factor indicates poor utilization of electrical power. To understand the power factor, you must understand how power is used.

Generally, two types of loads are placed on AC power lines:

- *Resistive*. Power converted into heat, light, motion, or work
- *Inductive*. Sustains an electromagnetic field, such as in a transformer or motor

A resistive load is often called *working power* and is measured in kilowatts (KW). An inductive load, on the other hand, is often called *reactive power* and is measured in kilovolt-amperes-reactive (KVAR). Working power and reactive power together make up *apparent power*, which is measured in kilovolt-amperes (KVA). The power factor is measured as the ratio of working power to apparent power, or working power/apparent power (KW/KVA). The ideal power factor is 1, where the working power and apparent power are the same.

The concept of a resistive load or working power is fairly easy to understand. For example, a light bulb that consumes 100W of power generates 100W worth of heat and light. This is a pure resistive load. An inductive load, on the other hand, is a little harder to understand. Think about a transformer, which has coil windings to generate an electromagnetic field and then induce current in another set of windings. A certain amount of power is required to saturate the windings and generate the magnetic field, even though no work is being done. A power transformer that is not connected to anything is a perfect example of a pure inductive load. An apparent power draw exists to generate the fields, but no working power exists because no actual work is being done.

When the transformer is connected to a load, it uses both working power and reactive power. In other words, power is consumed to do work (for example, if the transformer is powering a light bulb), and apparent power is used to maintain the electromagnetic field in the transformer windings. In an AC circuit, these loads can become out of sync or phase, meaning they don't peak at the same time, which can generate harmonic distortions back down the power line. I've seen examples where electric motors have caused distortions in television sets plugged in to the same power circuit.

PFC usually involves adding capacitance to the circuit to maintain the inductive load without drawing additional power from the line. This makes the working power and apparent power the same, which results in a power factor of 1. It usually isn't just as simple as adding some capacitors to a circuit, although that can be done and is called *passive* power factor correction. *Active* power factor correction involves a more intelligent circuit designed to match the resistive and inductive loads so they are seen as the same by the electrical outlet.

A power supply with active power factor correction draws low distortion current from the AC source and has a power factor rating of 0.9 or greater. A nonpower factor corrected supply draws highly distorted current and is sometimes referred to as a *nonlinear* load. The power factor of a noncorrected supply is typically 0.60.8. Therefore, only 60% of the apparent power consumed is actually doing real work!

Having a power supply with active PFC might or might not lower your electric bill (it depends on how your power is measured), but it will definitely reduce the load on the building wiring. With PFC, all the power going into the supply is converted into actual work and the wiring is less overworked. For example, if you ran a number of computers on a single breaker-controlled circuit and found that you were blowing the breaker periodically, you could switch to systems with active PFC power supplies and reduce the load on the wiring by up to 40%, meaning you would be less likely to blow the breaker.

The International Electrical Committee (IEC) has released standards dealing with the low-frequency public supply system. The initial standards were 555.2 (Harmonics) and 555.3 (Flicker), but they have since been refined and are now available as IEC 1000-3-2 and IEC 1000-3-3, respectively. As governed by the EMC directive, most electrical devices sold within the member countries of the EU must meet the IEC standards. The IEC1000-3-2/3 standards became mandatory in 1997 and 1998.

Even if you don't live in a country where PFC is required, I highly recommend specifying PC power supplies with active PFC. The main benefits of PFC supplies is that they do not overheat building wiring or distort the AC source waveform, which causes less interference on the line for other devices.

Power Supply Safety Certifications

Many agencies around the world certify electric and electronic components for safety and quality. The most commonly known agency in the United States is Underwriters Laboratories, Inc. (UL). UL standard #60950*Safety of Information Technology Equipment, Third Edition* covers power supplies and other PC components. You should always purchase power supplies and other devices that are UL-certified. It has often been said that, although not every good product is UL-certified, no bad products are.

In Canada, electric and electronic products are certified by the Canadian Standards Agency (CSA). The German equivalents are TÜV Rheinland and VDE, and NEMKO operates in Norway. These agencies are responsible for certification of products throughout Europe. Power supply manufacturers that sell to an international market should have products that are certified at least by UL, the CSA, and TÜV if not by all the agencies listed, and more.

Apart from UL-type certifications, many power supply manufacturers, even the most reputable ones, claim that their products have a Class B certification from the Federal Communications Commission, meaning that they meet FCC standards for electromagnetic and radio frequency interference (EMI/RFI). This is a contentious point, however, because the FCC does not certify power supplies as individual components. Title 47 of the Code of Federal Regulations, Part 15, Section 15.101(c) states as follows:

The FCC does NOT currently authorize motherboards, cases, and internal power supplies. Vendor claims that they are selling 'FCC-certified cases,' 'FCC-certified motherboards,' or 'FCC-certified internal power supplies' are false.

In fact, an FCC certification can be issued collectively only to a base unit consisting of a computer case, motherboard, and power supply. Thus, a power supply purported to be FCC-certified was actually certified along with a particular case and motherboard not necessarily the same case and motherboard you are using in your system. This does not mean, however, that the manufacturer is being deceitful or that the power supply is inferior. If anything, this means that when evaluating power supplies, you should place less weight on the FCC certification than on other factors, such as UL certification.

Power-Use Calculations

When expanding or upgrading your PC, you should ensure that your power supply is capable of providing sufficient current to power all the system's internal devices. One way to see whether your system is capable of expansion is to calculate the levels of power drain in the various system components and deduct the total from the maximum power supplied by the power supply. This calculation can help you decide whether you must upgrade the power supply to a more capable unit. Unfortunately, these calculations can be difficult to make because many manufacturers do not publish power consumption data for their products.

In addition, getting power-consumption data for many +5V devices, including motherboards and adapter cards, can be difficult. Motherboards can consume different power levels, depending on numerous factors. Most motherboards consume about 5 amps or so, but try to get information on the one you are using. For adapter cards, if you can find the actual specifications for the card, use those figures. To be on the conservative side, however, I usually go by the maximum available power levels set forth in the respective bus standards.

For example, consider the power-consumption figures for components in a modern PC, such as a desktop or Slimline system with a 200-watt power supply rated for 20 amps at +5V and 8 amps at +12V. The ISA specification calls for a maximum of 2.0 amps of +5V power and 0.175 amps of +12V power for each slot in the system. Most systems have eight slots, and you can assume that four are filled for the purposes of calculating power draw. The calculation shown in [Table 19.21](#) shows what happens when you subtract the amount of power necessary to run the various system components.

Table 19.21. Power Consumption Calculation

Available +5V Power (Amps): 20.0A		Available +12V Power (Amps): 8.0A	
Less: Motherboard	5.0A	Less: 4 slots filled at 0.175 each	0.7A
4 slots filled at 2.0 each	8.0A	3 1/2" hard disk drive motor	1.0A
3 1/2" floppy drive logic	0.5A	3 1/2" floppy drive motor	1.0A
3 1/2" hard disk drive logic	0.5A	Cooling fan motor	0.1A
CD-ROM/DVD drive logic	1.0A	CD-ROM/DVD drive motor	1.0A
Remaining Power (Amps):	5.0A	Remaining Power (Amps):	4.2A

In the preceding example, everything seems okay for now. With half the slots filled, a floppy drive, and one hard disk, the system still has room for more. Problems with the power supply could come up, however, if this system were expanded to the extreme. With every slot filled and two or more hard disks, problems with the +5V current definitely would occur. However, the +12V does seem to have room to spare. You could add a CD-ROM drive or a second hard disk without worrying too much about the +12V power, but the +5V power would be strained.

If you anticipate loading up a system to the extreme as in a high-end multimedia system, for example you might want to invest in the insurance of a higher-output power supply. For example, a 250-watt supply usually has 25 amps of +5V current and 10 amps of +12V current, whereas a 300-watt unit usually has 32 amps of +5V current available. These supplies enable you to fully load the system and are likely to be found in full-sized desktop or tower case configurations in which this type of expansion is expected.

Motherboards can draw anywhere from 4 to 15 amps or more of +5V power to run. Depending on which processor is installed, the figure can go higher. As an example, the AMD Athlon XP 3000+ (2.167GHz) processor draws up to 74.3 watts of 1.65V power, which is supplied by motherboard-based voltage regulators. These regulators are powered by +5V in most Socket A motherboards, so assuming an 80% (typical) efficiency in the regulator power conversion, this would equate to consuming 18.57 amps of +5V power. This, plus the power draw from the rest of the motherboard, would put the +5V power draw near the 24A30A maximum allowed by the power supply connectors.

By comparison, the 3.06GHz version of the Pentium 4 draws up to 81.8 watts of 1.55V power. Intel wisely decided that Pentium 4 systems were power hungry enough that the motherboard-based voltage regulators should run on +12V instead of +5V. Again, assuming an 80% efficiency, the regulators would require 20.45 amps if running on +5V but only 8.52 amps if running on +12V. By moving the regulators to the +12V power, the load on the +5V is greatly eased. If your motherboard has the ATX12V connector, you can be assured that the CPU voltage regulator module is running off +12V and not +5V.

Considering that systems with two or more processors are now becoming common, you could have up to 40 amps of +5V (using +5V-powered CPU voltage regulators) or up to 16 amps of +12V power being drawn by the processors alone. A dual processor system using +5V-based regulators would almost certainly exceed the 30A maximum allowable power draw through the ATX main and auxiliary connectors! Add in the power draw for the motherboard, video card, memory, and disk drives, and you'll see that very few "no-name" power supplies can supply this kind of current. For these applications, you should consider only high-quality, high-capacity power supplies from a reputable manufacturer, such as PC Power and Cooling.

In these calculations, bus slots are allotted maximum power in amps, as shown in [Table 19.22](#).

Table 19.22. Maximum Power Consumption in Amps per Bus Slot

Bus Type	+5V Power	+12V Power	+3.3V Power
ISA	2.0	0.175	n/a
EISA	4.5	1.5	n/a
VL-bus	2.0	n/a	n/a
16-bit MCA	1.6	0.175	n/a
32-bit MCA	2.0	0.175	n/a
PCI	5	0.5	7.6

As you can see from the table, ISA slots are allotted 2.0 amps of +5V and 0.175 amps of +12V power.

Note that these are maximum figures; not all cards draw this much power. If the slot has a VL-bus extension connector, an additional 2.0 amps of +5V power are allowed for the VL-bus.

Floppy drives can vary in power consumption, but most of the newer 3 1/2" drives have motors that run on +5V current in addition to the logic circuits. These drives usually draw 1.0 amp of +5V power and use no +12V at all. 5 1/4" drives use standard +12V motors that draw about 1.0 amp. These drives also require about 0.5 amps of +5V for the logic circuits. Most cooling fans draw about 0.1 amps of +12V power, which is negligible.

Typical 3 1/2" hard disks today draw about 1 amp of +12V power to run the motors and only about 0.5 amps of +5V power for the logic. 5 1/4" hard disks, especially those that are full-height, draw much more power. A typical full-height hard drive draws 2.0 amps of +12V power and 1.0 amp of +5V power.

Another problem with hard disks is that they require much more power during the spin-up phase of operation than during normal operation. In most cases, the drive draws double the +12V power during spin-up, which can be 4.0 amps or more for the full-height drives. This tapers off to a normal level after the drive is spinning.

The figures that most manufacturers report for maximum power supply output are full duty-cycle figures. The power supply can supply these levels of power continuously. You usually can expect a unit that continuously supplies a given level of power to be capable of exceeding this level for some non-continuous amount of time. A supply normally can offer 50% greater output than the continuous figure indicates for as long as 1 minute. Systems often use this cushion to supply the necessary power to spin up a hard disk drive. After the drive has spun to full speed, the power draw drops to a value within the system's continuous supply capabilities. Drawing anything over the rated continuous figure for any extended length of time causes the power supply to run hot and fail early, and it can create nasty symptoms in the system.

Tip

If you are using internal SCSI hard drives, you can ease the startup load on your power supply. The key is to enable the SCSI drive's Remote Start option, which causes the drive to start spinning only when it receives a startup command over the SCSI bus. The effect is that the drive remains stationary (drawing very little power) until the very end of the POST and spins up right when the SCSI portion of the POST begins.

If you have multiple SCSI drives, they all spin up sequentially based on their SCSI ID settings. This is designed so that only one drive is spinning up at any one time and so that no drives start spinning until the rest of the system has had time to start. This greatly eases the load on the power supply when you first power the system on.

In most cases, you enable Remote Start through your SCSI host adapter's setup program. This program might be supplied with the adapter on separate media, or it might be integrated into the adapter's BIOS and activated with a specific key combination at boot time.

The biggest cause of power supply overload problems has historically been filling up the expansion slots and adding more drives. Multiple hard drives, CD-ROM drives, and floppy drives can create quite a drain on the system power supply. Be sure you have enough +12V power to run all the drives you plan to install. Tower systems can be especially problematic because they have so many drive bays. Just because the case has room for the devices doesn't mean the power supply can support them. Be sure you have enough +5V

power to run all your expansion cards, especially PCI cards. It pays to be conservative, but remember that most cards draw less than the maximum allowed. Today's newest processors can have very high current requirements for the +5V or +3.3V supplies. When selecting a power supply for your system, be sure to take into account any future processor upgrades.

Many people wait until an existing component fails to replace it with an upgraded version. If you are on a tight budget, this "if it ain't broke, don't fix it" attitude might be necessary. Power supplies, however, often do not fail completely all at once; they can fail in an intermittent fashion or allow fluctuating power levels to reach the system, which results in unstable operation. You might be blaming system lockups on software bugs when the culprit is an overloaded power supply. In addition, an inadequate or failing supply causing lockups can result in file system corruption, which causes even further system instabilities (that could remain present even after replacing the power supply). If you use bus-powered USB devices, a failing power supply can also cause these devices to fail or malfunction. If you have been running your original power supply for a long time and have upgraded your system in other ways, you should expect some problems, and you might want to consider reloading the operating system and applications from scratch.

Although there is certainly an appropriate place for the exacting power-consumption calculations you've read about in this section, a great many experienced PC users prefer the "don't worry about it" power calculation method. This technique consists of buying or building a system with a good-quality 300-watt or higher power supply (or upgrading to such a supply in an existing system) and then upgrading the system freely, without concern for power consumption.

Tip

My preference is the 510W supply from PC Power and Cooling, which is probably overkill for most people, but for those who keep a system for a long time and put it through several upgrades, it is an excellent choice.

Unless you plan to build a system with arrays of SCSI drives and a dozen other peripherals, you will probably not exceed the capabilities of the power supply, and this method certainly requires far less effort.

Power Cycling

Should you turn off a system when it is not in use? To answer this frequent question, you should understand some facts about electrical components and what makes them fail. Combine this knowledge with information on power consumption, cost, and safety to come to your own conclusion. Because circumstances can vary, the best answer for your own situation might be different from the answer for others, depending on your particular needs and applications.

Frequently powering a system on and off does cause deterioration and damage to the components. This seems logical, but the simple reason is not obvious to most people. Many believe that flipping system power on and off frequently is harmful because it electrically "shocks" the system. The real problem, however, is temperature or thermal shock. As the system warms up, the components expand; as it cools off, the components contract. In addition, various materials in the system have different thermal expansion coefficients, so they expand and contract at different rates. Over time, thermal shock causes deterioration in many areas of a system.

From a pure system-reliability viewpoint, you should insulate the system from thermal shock as much as possible. When a system is turned on, the components go from ambient (room) temperature to as high as 185°F (85°C) within 30 minutes or less. When you turn off the system, the same thing happens in reverse, and the components cool back to ambient temperature in a short period of time.

Thermal expansion and contraction remains the single largest cause of component failure. Chip cases can split, allowing moisture to enter and contaminate them. Delicate internal wires and contacts can break, and circuit boards can develop stress cracks. Surface-mounted components expand and contract at rates different from the circuit boards on which they are mounted, causing enormous stress at the solder joints. Solder joints can fail due to the metal hardening from the repeated stress, resulting in cracks in the joint. Components that use heatsinks, such as processors, transistors, or voltage regulators, can overheat and fail because the thermal cycling causes heatsink adhesives to deteriorate and break the thermally conductive bond between the device and the heatsink. Thermal cycling also causes socketed devices and connections to loosen, or *creep*, which can cause a variety of intermittent contact failures.

◀◀ See "[SIMMs, DIMMs, and RIMMs](#)," p. [492](#).

Thermal expansion and contraction affect not only chips and circuit boards, but also things such as hard disk drives. Most hard drives today have sophisticated thermal compensation routines that make adjustments in head position relative to the expanding and contracting platters. Most drives perform this thermal compensation routine once every 5 minutes for the first 30 minutes the drive is running and then every 30 minutes thereafter. In older drives, this procedure can be heard as a rapid "tick-tick-tick-tick" sound.

In essence, anything you can do to keep the system at a constant temperature prolongs the life of the system, and the best way to accomplish this is to leave the system either permanently on or permanently off. Of course, if the system is never turned on in the first place, it should last a long time indeed!

Now, I am not saying that you should leave all systems on 24 hours a day. A system powered on and left unattended can be a fire hazard (I have witnessed at least two monitors spontaneously catch fireluckily, I was there at the time), is a data security risk (from cleaning crews and other nocturnal visitors), can be

easily damaged if moved while running, and wastes electrical energy.

I currently pay 8 cents for a kilowatt-hour of electricity. A typical desktop-style PC with display consumes at least 300 watts (0.3 kilowatt) of electricity (and that is a conservative estimate). This means it would cost 2.4 cents to run my typical PC for an hour. Multiplying by 168 hours in a week means that it would cost \$4.03 per week to run this PC continuously. If the PC were turned on at 9 a.m. and off at 5 p.m., it would be on only 40 hours per week and would cost only \$0.96a savings of \$3.07 per week! Multiply this savings by 100 systems, and you are saving \$307 per week. Multiply this by 1,000 systems, and you are saving \$3,070 per week! Using systems certified under the EPA Energy Star program (so-called green PCs) would account for an additional savings of around \$1 per system per weekor \$1,000 per week for 1,000 systems. The great thing about Energy Star systems is that the savings are even greater if the systems are left on for long periods of time because the power management routines are automatic.

Based on these facts, my recommendations are that you power on the systems at the beginning of the workday and off at the end of the workday. Do not power the systems off for lunch, breaks, or any other short periods of time. If you are a home user, leave your computer on if you are going to be using it later in the day or if instant access is important. I'd normally recommend home users turn off the system when leaving the house or when sleeping. Servers, of course, should be left on continuously. This seems to be the best compromise of system longevity with pure economics. No matter what, these are just guidelines; if it works better for you to leave your system on 24 hours a day, seven days a week, make it so.

Power Management

As the standard PC configuration has grown to include capabilities formerly considered options, the power requirements of the system have increased steadily. Larger displays, DVD-ROM drives, and more powerful graphics cards all need more power to run, and the result is that the cost of operating a PC has risen steadily. To address these concerns, several programs and standards have been developed with the aim of reducing the power needed to run a PC as much as possible.

For standard desktop systems, power management is a matter of economy and convenience. By turning off specific components of the PC when they are not in use, you can reduce the electric bill and avoid having to power the computer up and down manually.

For portable systems, power management is far more important. Adding DVD-ROMs, speakers, and other components to a laptop or notebook computer reduces even further what is in many cases a short battery life. By adding new power management technology, a portable system can supply power only to the components it actually needs to run, thus extending the life of the battery charge.

Energy Star Systems

The EPA has started a certification program for energy-efficient PCs and peripherals. To be a member of this program, the PC or display must drop to a power draw at the outlet of 30 watts or less during periods of inactivity. Systems that conform to this specification get to wear the Energy Star logo. This is a voluntary program; however, many PC manufacturers are finding that it helps them sell their systems if they can advertise these systems as energy efficient.

One problem with this type of system is that the motherboard and disk drives can go to sleep, which means they can enter a standby mode in which they draw very little power. This causes havoc with some of the older power supplies because the low power draw does not provide enough of a load for them to function properly. Most of the newer supplies on the market, which are designed to work with these systems, have a very low minimum-load specification. I suggest you ensure that the minimum load will be provided by the equipment in your system if you buy a power supply upgrade. Otherwise, when the PC goes to sleep, it might take a power switch cycle to wake it up again. This problem would be most noticeable if you invested in a very high-output supply and used it in a system that draws very little power to begin with.

Advanced Power Management

Advanced Power Management (APM) is a specification jointly developed by Intel and Microsoft that defines a series of interfaces between power management-capable hardware and a computer's operating system. When it is fully activated, APM can automatically switch a computer between five states, depending on the system's current activity. Each state represents a further reduction in power use, accomplished by placing unused components into a low-power mode. The five system states are as follows:

- *Full On.* The system is completely operational, with no power management occurring.
- *APM Enabled.* The system is operational, with some devices being power managed. Unused devices can be powered down and the CPU clock slowed or stopped.
- *APM Standby.* The system is not operational, with most devices in a low-power state. The CPU clock can be slowed or stopped, but operational parameters are retained in memory. When triggered by a specific user or system activity, the system can return to the APM Enabled state almost

instantaneously.

- *APM Suspend*. The system is not operational, with most devices unpowered. The CPU clock is stopped, and operational parameters are saved to disk for later restoration. When triggered by a wake-up event, the system returns to the APM Enabled state relatively slowly.
- *Off*. The system is not operational. The power supply is off.

APM requires support from both hardware and software to function. In this chapter, you've already seen how ATX-style power supplies can be controlled by software commands using the Power_On signal and the six-pin optional power connector. Manufacturers are also integrating the same type of control features into other system components, such as motherboards, monitors, and disk drives.

Operating systems that support APM, such as Windows, trigger power management events by monitoring the activities performed by the computer user and the applications running on the system. However, the OS does not directly address the power management capabilities of the hardware.

A system can have many hardware devices and many software functions participating in APM functions, which makes communication difficult. To address this problem, both the operating system and the hardware have an abstraction layer that facilitates communication between the various elements of the APM architecture.

The operating system runs an APM driver that communicates with the various applications and software functions that trigger power management activities, while the system's APM-capable hardware devices all communicate with the system BIOS. The APM driver and the BIOS communicate directly, completing the link between the OS and the hardware.

Thus, for APM to function, support for the standard must be built in to the system's individual hardware devices, the system BIOS, and the operating system (which includes the APM driver). Without all these components, APM activities can't occur.

Advanced Configuration and Power Interface

Advanced Configuration and Power Interface (ACPI) is a newer power management and system configuration standard supported by newer system BIOS software running Windows 98 and later operating systems. If your BIOS and operating system support ACPI, full power management control is now done by the operating system rather than by the BIOS. ACPI is intended to offer a single place for power management and system configuration control; in the past, with APM you often could make power management settings in the BIOS setup as well as the operating system that overlapped or could have conflicting settings. ACPI is supported in newer systems in lieu of APM.

Tip

If, for any reason, you find that power management activities cause problems on your system, such as operating system freeze-ups or hardware malfunctions, the easiest way to disable APM is through the system BIOS. Most BIOSs that support APM include an option to disable it. This breaks the chain of communication between the operating system and the hardware, causing all power management activities to cease. Although you also can achieve the same end by removing the APM driver from the operating system, the Windows Plug and Play (PnP) feature detects the system's APM capabilities whenever you restart the computer and attempts to reinstall the APM driver.

If you have a newer system with ACPI, you can disable the power management settings via

the Power Management icon in the Windows Control Panel.

Power Supply Troubleshooting

Troubleshooting the power supply basically means isolating the supply as the cause of problems within a system and, if necessary, replacing it.

Caution

It is rarely recommended that an inexperienced user open a power supply to make repairs because of the dangerous high voltages present. Even when unplugged, power supplies can retain dangerous voltage and must be discharged (like a monitor) before service. Such internal repairs are beyond the scope of this book and are specifically not recommended unless the technician knows what she is doing.

Many symptoms lead me to suspect that the power supply in a system is failing. This can sometimes be difficult for an inexperienced technician to see because at times little connection seems to exist between the symptom and the cause the power supply.

For example, in many cases a parity check error message can indicate a problem with the power supply. This might seem strange because the parity check message specifically refers to memory that has failed. The connection is that the power supply powers the memory, and memory with inadequate power fails.

It takes some experience to know when this type of failure is power related and not caused by the memory. One clue is the repeatability of the problem. If the parity check message (or other problem) appears frequently and identifies the same memory location each time, I would suspect that defective memory is the problem. However, if the problem seems random, or if the memory location the error message cites as having failed seems random, I would suspect improper power as the culprit. The following is a list of PC problems that often are related to the power supply:

- Any power-on or system startup failures or lockups
- Spontaneous rebooting or intermittent lockups during normal operation
- Intermittent parity check or other memory-type errors
- Hard disk and fan simultaneously failing to spin (no +12V)
- Overheating due to fan failure
- Small brownouts that cause the system to reset
- Electric shocks felt on the system case or connectors
- Slight static discharges that disrupt system operation
- Erratic recognition of bus-powered USB peripherals

In fact, just about any intermittent system problem can be caused by the power supply. I always suspect the supply when flaky system operation is a symptom. Of course, the following fairly obvious symptoms point right to the power supply as a possible cause:

- System that is completely dead (no fan, no cursor)
- Smoke

- Blown circuit breakers

If you suspect a power supply problem, some of the simple measurements and the more sophisticated tests outlined in this section can help you determine whether the power supply is at fault. Because these measurements might not detect some intermittent failures, you might have to use a spare power supply for a long-term evaluation. If the symptoms and problems disappear when a known good spare unit is installed, you have found the source of your problem.

Following is a simple flowchart to help you zero in on common power supply-related problems:

1.

Check the AC power input. Make sure the cord is firmly seated in the wall socket and in the power supply socket. Try a different cord.

2.

Check the DC power connections. Make sure the motherboard and disk drive power connectors are firmly seated and making good contact. Check for loose screws.

3.

Check the DC power output. Use a digital multimeter to check for proper voltages. If it's below spec, replace the power supply.

4.

Check the installed peripherals. Remove all boards and drives and retest the system. If it works, add items back in one at a time until the system fails again. The last item added before the failure returns is likely defective.

Many types of symptoms can indicate problems with the power supply. Because the power supply literally powers everything else in the system, everything from disk drive problems to memory problems to motherboard problems can often be traced back to the power supply as the root cause.

Overloaded Power Supplies

A weak or inadequate power supply can put a damper on your ideas for system expansion. Some systems are designed with beefy power supplies, as if to anticipate a great deal of system add-ons and expansion components. Most desktop or tower systems are built in this manner. Some systems have inadequate power supplies from the start, however, and can't adequately service the power-hungry options you might want to add.

The wattage rating can sometimes be very misleading. Not all 300-watt supplies are created the same. People familiar with high-end audio systems know that some watts are better than others. This is true for power supplies, too. Cheap power supplies might in fact put out the rated power, but what about noise and distortion? Some of the supplies are under-engineered to just barely meet their specifications, whereas others might greatly exceed their specifications. Many of the cheaper supplies provide noisy or unstable power, which can cause numerous problems with the system. Another problem with under-engineered

power supplies is that they can run hot and force the system to do so as well. The repeated heating and cooling of solid-state components eventually causes a computer system to fail, and engineering principles dictate that the hotter a PC's temperature, the shorter its life. Many people recommend replacing the original supply in a system with a heavier-duty model, which solves the problem. Because power supplies come in common form factors, finding a heavy-duty replacement for most systems is easy, as is the installation process.

Inadequate Cooling

Some of the available replacement power supplies have higher-capacity cooling fans than the originals, which can greatly prolong system life and minimize overheating problems especially for the newer, hotter-running processors. If system noise is a problem, models with special fans can run more quietly than the standard models. These power supplies often use larger-diameter fans that spin more slowly, so they run more quietly but move the same amount of air as the smaller fans. PC Power and Cooling specializes in heavy-duty and quiet supplies.

Ventilation in a system is also important. You must ensure adequate airflow to cool the hotter items in the system. In most prebuilt systems, this is not much of a concern because most reputable manufacturers ensure that their systems have adequate ventilation to avoid overheating. If, however, you're building or upgrading a system, it's critical that your processor is cooled by an active heatsink and that the case include one or more cooling fans for additional ventilation. If you have free expansion slots, you should space out the boards in your system to permit airflow between them. Place the hottest-running boards nearest the fan or the ventilation holes in the system. Make sure that adequate airflow exists around the hard disk drive, especially for those that spin at high rates of speed. Some hard disks can generate quite a bit of heat during operation. If the hard disks overheat, data can be lost.

Always be sure you run your computer with the case cover on, especially if you have an older, loaded system using passive heatsinks. Removing the cover in that situation can actually cause the system to overheat. With the cover off, the power supply and chassis fans no longer draw air through the system. Instead, the fans end up cooling only the supply, and the rest of the system must be cooled by simple convection. Systems that use an active heatsink on the processor aren't as prone to this type of problem; in fact, the cooler air from outside the normally closed chassis can help them to run cooler.

In addition, be sure that any empty slot positions have the filler brackets installed. If you leave these brackets off after removing a card, the resultant hole in the case disrupts the internal airflow and can cause higher internal temperatures.

If you experience intermittent problems that you suspect are related to overheating, a higher-capacity replacement power supply is usually the best cure. Specially designed supplies with additional cooling fan capacity also can help. At least one company sells a device called a fan card, but I am not convinced these are a good idea. Unless the fan is positioned to draw air to or from outside the case, all it does is blow hot air around inside the system and provide a spot cooling effect for anything it is blowing on. In fact, adding fans in this manner can contribute to the overall heat inside the system because the fan consumes power and generates heat.

CPU and graphics card-mounted fans are an exception because they are designed only for spot cooling of the CPU or GPU. These two chips run so much hotter than the other components in the system that a conventional, passive heatsink can't do the job. In this case, a dedicated active heatsink placed directly over the chip draws heat away from it and provides a spot-cooling effect that keeps chip temperatures down. One drawback to these active processor cooling fans is that the processor could overheat instantly and be damaged if the heatsink's fan should fail. Most Intel processors since the Pentium III and current AMD processors have built-in safeguards that prevent damage by automatically shutting down the system or by throttling back the chip's clock speed if it overheats. Still, it is best not to depend on these safeguards

because not all processors have them.

Using Digital Multimeters

One simple test you can perform on a power supply is to check the output voltages. This shows whether a power supply is operating correctly and whether the output voltages are within the correct tolerance range. Note that you must measure all voltages with the power supply connected to a proper load, which usually means testing while the power supply is still installed in the system and connected to the motherboard and peripheral devices.

Selecting a Meter

You need a simple digital multimeter (DMM) or digital volt-ohm meter (DVOM) to perform voltage and resistance checks on electronic circuits (see [Figure 19.37](#)). You should use only a DMM instead of the older needle-type multimeters because the older meters work by injecting 9V into the circuit when measuring resistance, which damages most computer circuits.

Figure 19.37. A typical DMM.

A DMM uses a much smaller voltage (usually 1.5V) when making resistance measurements, which is safe for electronic equipment. You can get a good DMM with many features from several sources. I prefer the small, pocket-size meters for computer work because they are easy to carry around.

Some features to look for in a good DMM are as follows:

- *Pocket size.* This is self-explanatory, but small meters that have many, if not all, of the features of larger ones are available. The elaborate features found on some of the larger meters are not really necessary for computer work.
- *Overload protection.* If you plug the meter into a voltage or current beyond the meter's capability to measure, the meter protects itself from damage. Cheaper meters lack this protection and can be easily damaged by reading current or voltage values that are too high.
- *Autoranging.* The meter automatically selects the proper voltage or resistance range when making measurements. This is preferable to the manual range selection; however, really good meters offer both autoranging capability and a manual range override.
- *Detachable probe leads.* The leads easily can be damaged, and sometimes a variety of differently shaped probes are required for different tests. Cheaper meters have the leads permanently attached, which means you can't easily replace them. Look for a meter with detachable leads that plug in to the meter.
- *Audible continuity test.* Although you can use the ohm scale for testing continuity (0 ohms indicates continuity), a continuity test function causes the meter to produce a beep noise when continuity exists between the meter test leads. By using the sound, you quickly can test cable assemblies and other items for continuity. After you use this feature, you will never want to use the ohms display for this purpose again.
- *Automatic power off.* These meters run on batteries, and the batteries can easily be worn down if the meter is accidentally left on. Good meters have an automatic shutoff that turns off the unit when it senses no readings for a predetermined period of time.
- *Automatic display hold.* This feature enables you to hold the last stable reading on the display even after the reading is taken. This is especially useful if you are trying to work in a difficult-to-reach area single-handedly.
- *Minimum and maximum trap.* This feature enables the meter to trap the lowest and highest readings in memory and hold them for later display, which is especially useful if you have readings that are fluctuating too quickly to see on the display.

Although you can get a basic pocket DMM for as little as \$20, one with all these features is priced closer to \$100, and some can be much higher. RadioShack carries some nice inexpensive units, and you can purchase the high-end models from electronics supply houses, such as Newark or Digi-Key.

Measuring Voltage

To measure voltages on a system that is operating, you must use a technique called *back probing* on the connectors (see [Figure 19.38](#)). You can't disconnect any of the connectors while the system is running, so you must measure with everything connected. Nearly all the connectors you need to probe have openings in the back where the wires enter the connector. The meter probes are narrow enough to fit into the connector alongside the wire and make contact with the metal terminal inside. The technique is called back probing because you are probing the connector from the back. You must use this back-probing technique to perform virtually all the following measurements.

Figure 19.38. Back probing the power supply connectors.

[\[View full size image\]](#)

To test a power supply for proper output, check the voltage at the Power_Good pin (P8-1 on AT, Baby-AT, and LPX supplies; pin 8 on the ATX-type connector) for +3V to +6V of power. If the measurement is not within this range, the system never sees the Power_Good signal and therefore does not start or run properly. In most cases, the power supply is bad and must be replaced.

Continue by measuring the voltage ranges of the pins on the motherboard and drive power connectors. If you are measuring voltages for testing purposes, any reading within 10% of the specified voltage is considered acceptable, although most manufacturers of high-quality power supplies specify a tighter 5% tolerance. For ATX power supplies, the specification requires that voltages must be within 5% of the rating, except for the 3.3V current, which must be within 4%. The following table shows the voltage ranges within these tolerances.

	Loose Tolerance		Tight Tolerance	
Desired Voltage	Min. (10%)	Max. (+8%)	Min. (5%)	Max. (+5%)
+3.3V	2.97V	3.63V	3.135V	3.465V
+5.0V	4.5V	5.4V	4.75V	5.25V
+12.0V	10.8V	12.9V	11.4V	12.6V

The Power_Good signal has tolerances that are different from the other voltages, although it is nominally

+5V in most systems. The trigger point for Power_Good is about +2.4V, but most systems require the signal voltage to be within the tolerances listed here:

Signal	Minimum	Maximum
Power_Good (+5V)	3.0V	6.0V

Replace the power supply if the voltages you measure are out of these ranges. Again, it is worth noting that any and all power supply tests and measurements must be made with the power supply properly loaded, which usually means it must be installed in a system and the system must be running.

Specialized Test Equipment

You can use several types of specialized test gear to test power supplies more effectively. Because the power supply is one of the most failure-prone items in PCs today, you should have these specialized items if you service many PC systems.

Digital Infrared Thermometer

One of the greatest additions to my toolbox is a digital infrared thermometer (illustrated in Chapter 24, "[PC Diagnostics, Testing, and Maintenance](#)"). They also are called noncontact thermometers because they measure by sensing infrared energy without having to touch the item they are reading. This enables me to make instant spot checks of the temperature of a chip, a board, or the system chassis. They are available from companies such as Raytek (<http://www.raytek.com>) for less than \$100. To use these handheld items, you point at an object and then pull the trigger. Within seconds, the display shows a temperature readout accurate to $\pm 3^{\circ}\text{F}$ (2°C). These devices are invaluable in checking to ensure the components in your system are adequately cooled.

Variable Voltage Transformer

When testing power supplies, it is sometimes desirable to simulate different AC voltage conditions at the wall socket to observe how the supply reacts. A variable voltage transformer is a useful test device for checking power supplies because it enables you to exercise control over the AC line voltage used as input for the power supply (see [Figure 19.39](#)). This device consists of a large transformer mounted in a housing with a dial indicator that controls the output voltage. You plug the line cord from the transformer into the wall socket and plug the PC power cord into the socket provided on the transformer. The knob on the transformer can be used to adjust the AC line voltage the PC receives.

Figure 19.39. A variable voltage transformer.

Most variable transformers can adjust their AC outputs from 0V to 140V no matter what the AC input (wall socket) voltage is. Some can cover a range from 0V to 280V, as well. You can use the transformer to simulate brownout conditions, enabling you to observe the PC's response. Thus, you can check a power supply for proper Power_Good signal operation, among other things.

By running the PC and dropping the voltage until the PC shuts down, you can see how much reserve is in the power supply for handling a brownout or other voltage fluctuations. If your transformer can output voltages in the 200V range, you can test the capability of the power supply to run on foreign voltage levels. A properly functioning supply should operate between 90V and 135V but should shut down cleanly if the voltage is outside that range.

One indication of a problem is seeing parity check-type error messages when you drop the voltage to 80V. This indicates that the Power_Good signal is not being withdrawn before the power supply output to the PC fails. The PC should simply stop operating as the Power_Good signal is withdrawn, causing the system to enter a continuous reset loop.

Variable voltage transformers are sold by a number of electronic parts supply houses, such as Newark, InOne and Digi-Key. You should expect to pay anywhere from \$100 to \$300 for this device.

Repairing the Power Supply

Hardly anyone actually repairs power supplies anymore, primarily because simply replacing the supply with a new one is usually cheaper. Even high-quality power supplies are not that expensive when compared to the labor required to repair them.

A defective power supply is typically discarded unless it happens to be one of the higher-quality or more expensive units. In that case, it is usually wise to send the supply to a company that specializes in repairing power supplies and other components. These companies normally provide what is called depot repair, which means you send the supply to them and they repair it and return it to you. If time is of the essence, most of the depot repair companies immediately send you a functional equivalent to your defective supply and take yours in as a core charge. Depot repair is the recommended way to service many PC components, such as power supplies, monitors, and printers. If you take your PC to a conventional service outlet, they often determine which component has the problem and send it to be depot repaired. You can do that yourself and save the markup the repair shop usually charges in such cases.

For those with experience around high voltages, you might be able to repair a failing supply with two relatively simple operations (replacing the internal fuse or the fan); however, these require opening the supply something I do not normally recommend. I mention it only as an alternative to replacement in some cases. Besides, in all cases where I've seen the internal fuse blown, there were more serious problems and just replacing the fuse only caused it to immediately blow again. On the other hand, if the only problem with the supply is that the fan has failed (motor or bearing failure), you might be able to save the supply from the trash by simply replacing the internal fan.

Most manufacturers try to prevent you from entering the supply by sealing it with special tamperproof Torx screws. These screws use the familiar Torx star driver but also have a tamper-prevention pin in the center that prevents a standard driver from working. Most tool companies, such as Jensen or Specialized, sell sets of TT (tamperproof Torx) bits that remove the tamper-resistant screws. Other manufacturers rivet the power supply case shut, which means you must drill out the rivets to gain access.

Caution

The manufacturers place these obstacles there for a reason to prevent entry by those who are inexperienced with high voltage. Consider yourself warned!

Obtaining Replacement Units

Most of the time, it is simply easier, safer, or less expensive (considering the time and materials involved) to replace the power supply than to repair it. As mentioned earlier, replacement power supplies are available from many manufacturers. Before you can shop for a supplier, however, you should consider other purchasing factors.

Deciding on a Power Supply

When you are shopping for a new power supply, you should take several factors into account. First, consider the power supply's shape, or form factor. Power supply form factors can differ in their physical sizes, shapes, screw-hole positions, connector types, and fan locations. When ordering a replacement supply, you need to know which form factor your system requires.

Some systems use proprietary power supply designs, which makes replacement more difficult. If a system uses one of the industry-standard form factor power supplies, replacement units with a variety of output levels and performance are available from hundreds of vendors. An unfortunate user of a system with a nonstandard form factor supply does not have this kind of choice and must get a replacement from the original manufacturer of the system and usually must pay a much higher price for the unit. Although you can find high-quality, industry-standard form factor supplies for less than \$50, the proprietary units from some manufacturers cost as much as \$400 or more. PC buyers often overlook this and discover too late the consequences of having nonstandard components in a system.

◀◀ See "[Power Supply Form Factors](#)," p. [1148](#).

Name-brand systems on both the low and high end of the price scale are notorious for using proprietary form factor power supplies. For example, Dell has been using proprietary supplies in many of its systems. Be sure you consider this if you intend to own or use these types of systems out of warranty or plan significant upgrades during the life of the system. Personally, I always insist on systems that use industry-standard power supplies, such as the ATX12V form factor supply found in most systems today.

Sources for Replacement Power Supplies

Because one of the most failure-prone items in PC systems is the power supply, I am often asked to recommend a replacement. Literally hundreds of companies manufacture PC power supplies, and I certainly have not tested them all. I can, however, recommend some companies whose products I have come to know and trust.

Although other high-quality manufacturers exist, at this time I recommend power supplies from PC Power and Cooling and Antec.

PC Power and Cooling has a complete line of power supplies for PC systems. It makes supplies in most of the standard PC form factors used today. Versions are available in a variety of quality and output levels, from inexpensive replacements to very high-quality, high-output models with ratings of up to 1,000 watts or more. It even makes versions with high-volume, low-speed (quiet) fan assemblies. Its quiet models are especially welcome to people who work in quiet homes or offices and are annoyed by the fan noise some

power supplies emanate. My favorite models are PC Power and Cooling's Silencer 470 ATX for building quieter systems, Turbo-Cool 510 Express for systems that need the optional PCI Express x16 power connectors, and the Turbo-Cool 1KW (rated at 1,000 watts, it's one of the most powerful power supplies on the market).

Tip

PC Power and Cooling has SFX-style supplies that can be used to upgrade small form factor systems, including E-machines, HP's 67xx series, and others. If you have one of these systems and need a high-quality replacement supply to support your upgrades, PC Power and Cooling can help.

PC Power and Cooling also has units available that fit some of Dell's proprietary designs produced between 1996 and 2000. These units cost less than Dell's, are available with significantly higher output ratings, and bolt in as direct replacements.

Antec, Inc., also offers high-quality power supplies, particularly its TruePower series. It also offers power supplies that can operate with no internal fan, resulting in the quietest design possible. It even has some power supplies with internal lighting for interesting visual effects when installed in windowed cases.

A high-quality power supply from either of these vendors can be one of the best cures for intermittent system problems and can go a long way toward ensuring trouble-free operation in the future.

Power Supply Tips and Recommendations

With backward compatibility ensuring that the new 24-pin ATX power connector will plug in to older 20-pin motherboard sockets, when purchasing a new power supply I now recommend only those units that include 24-pin main power connectors, which are usually sold as ATX12V 2.x or PCI Express models. For the most flexible and future-proof supply, also ensure that the power supply includes a 6-pin PCI Express graphics connector as well as integrated SATA drive power connectors. An example of a highly rated power supply incorporating all these features is the Turbo-Cool 510 Express/SLI from PC Power and Cooling (www.pcpowercooling.com). Choosing a power supply with these features provides flexibility that allows it to work not only in newer systems, but also in virtually all older ATX systems and with no adapters required.

◀◀ See "[ATX12V 2.x 24-pin Main Power Connector](#)," p. [1178](#).

Power-Protection Systems

Power-protection systems do just what the name implies: They protect your equipment from the effects of power surges and power failures. In particular, power surges and spikes can damage computer equipment, and a loss of power can result in lost data. In this section, you learn about the four primary types of power-protection devices available and when you should use them.

Before considering any further levels of power protection, you should know that a quality power supply already affords you a substantial amount of protection. High-end power supplies from the vendors I recommend are designed to provide protection from higher-than-normal voltages and currents, and they provide a limited amount of power-line noise filtering. Some of the inexpensive aftermarket power supplies probably do not have this sort of protection. If you have an inexpensive computer, further protecting your system might be wise.

Caution

All the power-protection features in this chapter and the protection features in the power supply inside your computer require that the computer's AC power cable be connected to a ground.

Many older homes do not have three-prong (grounded) outlets to accommodate grounded devices.

Do not use a three-pronged adapter (that bypasses the three-prong requirement and enables you to connect to a two-prong socket) to plug a surge suppressor, computer, or UPS into a two-pronged outlet. They often don't provide a good ground and can inhibit the capabilities of your power-protection devices.

You also should test your power sockets to ensure they are grounded. Sometimes outlets, despite having three-prong sockets, are not connected to a ground wire; an inexpensive socket tester (available at most hardware stores) can detect this condition.

Of course, the easiest form of protection is to turn off and unplug your computer equipment (including your modem) when a thunderstorm is imminent. However, when this is not possible, other alternatives are available.

Power supplies should stay within operating specifications and continue to run a system even if any of these power line disturbances occur:

- Voltage drop to 80V for up to 2 seconds
- Voltage drop to 70V for up to .5 seconds
- Voltage surge of up to 143V for up to 1 second

Most high-quality power supplies (or the attached systems) will not be damaged by the following occurrences:

- Full power outage
- Any voltage drop (brownout)
- A spike of up to 2,500V

Because of their internal protection, many computer manufacturers that use high-quality power supplies state in their documentation that external surge suppressors are not necessary with their systems.

To verify the levels of protection built in to the existing power supply in a computer system, an independent laboratory subjected several unprotected PC systems to various spikes and surges of up to 6,000V considered the maximum level of surge that can be transmitted to a system through an electrical outlet. Any higher voltage would cause the power to arc to the ground within the outlet. None of the systems sustained permanent damage in these tests. The worst thing that happened was that some of the systems rebooted or shut down when the surge was more than 2,000V. Each system restarted when the power switch was toggled after a shutdown.

I do not use any real form of power protection on my systems, and they have survived near-direct lightning strikes and powerful surges. The most recent incident, only 50 feet from my office, was a direct lightning strike to a brick chimney that blew the top of the chimney apart. None of my systems (which were running at the time) were damaged in any way from this incident; they just shut themselves down. I was able to restart each system by toggling the power switches. An alarm system located in the same office, however, was destroyed by this strike. I am not saying that lightning strikes or even much milder spikes and surges can't damage computer systems another nearby lightning strike did destroy a modem and serial adapter installed in one of my systems. I was just lucky that the destruction did not include the motherboard.

This discussion points out an important oversight in some power-protection strategies: Do not forget to provide protection from spikes and surges on the phone line.

The automatic shutdown of a computer during power disturbances is a built-in function of most high-quality power supplies. You can reset the power supply by flipping the power switch from on to off and back on again. Some power supplies even have an auto-restart function. This type of power supply acts the same as others in a massive surge or spike situation: It shuts down the system. The difference is that after normal power resumes, the power supply waits for a specified delay of 36 seconds and then resets itself and powers the system back up. Because no manual switch resetting is required, this feature might be desirable in systems functioning as network servers or in those found in other unattended locations.

The first time I witnessed a large surge that caused an immediate shutdown of all my systems, I was extremely surprised. All the systems were silent, but the monitor and modem lights were still on. My first thought was that everything was blown, but a simple toggle of each system-unit power switch caused the power supplies to reset, and the units powered up with no problem. Since that first time, this type of shutdown has happened to me several times, always without further problems.

The following types of power-protection devices are explained in the sections that follow:

- Surge suppressors
- Phone-line surge protectors
- Line conditioners
- Standby power supplies (SPS)
- Uninterruptible power supplies (UPS)

Surge Suppressors (Protectors)

The simplest form of power protection is any one of the commercially available surge protectorsthat is, devices inserted between the system and the power line. These devices, which cost between \$20 and \$200, can absorb the high-voltage transients produced by nearby lightning strikes and power equipment. Some surge protectors can be effective for certain types of power problems, but they offer only very limited protection.

Surge protectors use several devices, usually metal-oxide varistors (MOVs), that can clamp and shunt away all voltages above a certain level. MOVs are designed to accept voltages as high as 6,000V and divert any power above 200V to ground. MOVs can handle normal surges, but powerful surges such as direct lightning strikes can blow right through them. MOVs are not designed to handle a very high level of power and self-destruct while shunting a large surge. These devices therefore cease to function after either a single large surge or a series of smaller ones. The real problem is that you can't easily tell when they no longer are functional. The only way to test them is to subject the MOVs to a surge, which destroys them. Therefore, you never really know whether your so-called surge protector is protecting your system.

Some surge protectors have status lights that let you know when a surge large enough to blow the MOVs has occurred. A surge suppressor without this status indicator light is useless because you never know when it has stopped protecting.

Underwriters Laboratories has produced an excellent standard that governs surge suppressors, called UL 1449. Any surge suppressor that meets this standard is a very good one and definitely offers a line of protection beyond what the power supply in your PC already offers. The only types of surge suppressors worth buying, therefore, should have two features:

- Conformance to the UL 1449 standard
- A status light indicating when the MOVs are blown

Units that meet the UL 1449 specification say so on the packaging or directly on the unit. If this standard is not mentioned, it does not conform. Therefore, you should avoid it.

Another good feature to have in a surge suppressor is a built-in circuit breaker that can be manually reset rather than a fuse. The breaker protects your system if it or a peripheral develops a short. These better surge suppressors usually cost about \$40.

Phone Line Surge Protectors

In addition to protecting the power lines, it is critical to provide protection to your systems from any connected phone lines. If you are using a modem or fax board that is plugged in to the phone system, any surges or spikes that travel through the phone line can damage your system. In many areas, the phone lines are especially susceptible to lightning strikes, which are the leading cause of fried modems and damage to the computer equipment attached to them.

Several companies manufacture or sell simple surge protectors that plug in between your modem and the phone line. These inexpensive devices can be purchased from most electronics supply houses. Most of the cable and communication product vendors listed in the Vendor List (on the disc that accompanies this book) sell these phone line surge protectors. Some of the standard power line surge protectors include connectors for phone line protection as well.

Line Conditioners

In addition to high-voltage and current conditions, other problems can occur with incoming power. The voltage might dip below the level needed to run the system, resulting in a brownout. Forms of electrical noise other than simple voltage surges or spikes might travel through the power line, such as radio-frequency interference or electrical noise caused by motors or other inductive loads.

Remember two things when you wire together digital devices (such as computers and their peripherals):

- Any wire can act as an antenna and have voltage induced in it by nearby electromagnetic fields, which can come from other wires, telephones, CRTs, motors, fluorescent fixtures, static discharge, and, of course, radio transmitters.
- Digital circuitry responds with surprising efficiency to noise of even a volt or two, making those induced voltages particularly troublesome. The electrical wiring in your building can act as an antenna, picking up all kinds of noise and disturbances.

A line conditioner can handle many of these types of problems. A line conditioner is designed to remedy a variety of problems. It filters the power, bridges brownouts, suppresses high-voltage and current conditions, and generally acts as a buffer between the power line and the system. A line conditioner does the job of a surge suppressor, and much more. It is more of an active device, functioning continuously, rather than a passive device that activates only when a surge is present. A line conditioner provides true power conditioning and can handle myriad problems. It contains transformers, capacitors, and other circuitry that can temporarily bridge a brownout or low-voltage situation. These units usually cost \$100-\$300, depending on the power-handling capacity of the unit.

Backup Power

The next level of power protection includes backup power-protection devices. These units can provide power in case of a complete blackout, thereby providing the time necessary for an orderly system shutdown. Two types are available: the standby power supply (SPS) and the uninterruptible power supply (UPS). The UPS is a special device because it does much more than just provide backup power; it is also the best kind of line conditioner you can buy.

Standby Power Supplies

A standby power supply is known as an offline device: It functions only when normal power is disrupted. An SPS system uses a special circuit that can sense the AC line current. If the sensor detects a loss of power on the line, the system quickly switches over to a standby battery and power inverter. The power inverter converts the battery power to 120V AC power, which is then supplied to the system.

SPS systems do work, but sometimes a problem occurs during the switch to battery power. If the switch is not fast enough, the computer system shuts down or reboots anyway, which defeats the purpose of having the backup power supply. A truly outstanding SPS adds to the circuit a ferroresonant transformer, which is a large transformer with the capability to store a small amount of power and deliver it during the switch time. This device functions as a buffer on the power line, giving the SPS almost uninterruptible capability.

Tip

Look for SPS systems with a switch-over time of less than 10 milliseconds (ms). This is shorter than the hold-over time of typical power supplies.

SPS units also might have internal line conditioning of their own. Under normal circumstances, most cheaper units place your system directly on the regular power line and offer no conditioning. The addition of a ferroresonant transformer to an SPS gives it extra regulation and protection capabilities because of the buffer effect of the transformer. SPS devices without the ferroresonant transformer still require the use of a line conditioner for full protection. SPS systems usually cost between a hundred and several thousand dollars, depending on the quality and power-output capacity.

Uninterruptible Power Supplies

Perhaps the best overall solution to any power problem is to provide a power source that is conditioned and that can't be interrupted—which is the definition of an uninterruptible power supply. UPSs are known as online systems because they continuously function and supply power to your computer systems. Because some companies advertise ferroresonant SPS devices as though they were UPS devices, many now use the term *true UPS* to describe a truly online system. A true UPS system is constructed in much the same way as an SPS system; however, because the computer is always operating from the battery, there is no switching circuit.

In a true UPS, your system always operates from the battery. A voltage inverter converts from +12V DC to 120V AC. You essentially have your own private power system that generates power independently of the AC line. A battery charger connected to the line or wall current keeps the battery charged at a rate equal to or greater than the rate at which power is consumed.

When the AC current supplying the battery charger fails, a true UPS continues functioning undisturbed because the battery-charging function is all that is lost. Because the computer was already running off the battery, no switch takes place and no power disruption is possible. The battery begins discharging at a rate dictated by the amount of load your system places on the unit, which (based on the size of the battery) gives you plenty of time to execute an orderly system shutdown. Based on an appropriately scaled storage battery, the UPS functions continuously, generating power and preventing unpleasant surprises. When the line power returns, the battery charger begins recharging the battery, again with no interruption.

Note

Occasionally, a UPS can accumulate too much storage and not enough discharge. When this occurs, the UPS emits a loud alarm, alerting you that it's full. Simply unplugging the unit from the AC power source for a while can discharge the excess storage (as it powers your computer) and drain the UPS of the excess.

Many SPS systems are advertised as though they are true UPS systems. The giveaway is the unit's switch time. If a specification for switch time exists, the unit can't be a true UPS because UPS units never switch. However, a good SPS with a ferroresonant transformer can virtually equal the performance of a true UPS at a lower cost.

Note

Many UPSs and SPSs today come equipped with a cable and software that enables the protected computer to shut down in an orderly manner on receipt of a signal from the UPS. This way, the system can shut down properly even if the computer is unattended. Some operating systems designed for server environments, such as Windows NT/2000/XP, contain

their own UPS software components.

UPS cost is a direct function of both the length of time it can continue to provide power after a line current failure and how much power it can provide. You therefore should purchase a UPS that provides enough power to run your system and peripherals and enough time to close files and provide an orderly shutdown. Remember, however, to manually perform a system shutdown procedure during a power outage. You will probably need your monitor plugged in to the UPS and the computer. Be sure the UPS you purchase can provide sufficient power for all the devices you must connect to it.

Because of a true UPS's almost total isolation from the line current, it is unmatched as a line conditioner and surge suppressor. The best UPS systems add a ferroresonant transformer for even greater power conditioning and protection capability. This type of UPS is the best form of power protection available. The price, however, can be high. To find out just how much power your computer system requires, look at the UL sticker on the back of the unit. This sticker lists the maximum power draw in watts, or sometimes in just volts and amperes. If only voltage and amperage are listed, multiply the two figures to calculate the wattage.

As an example, if the documentation for a system indicates that the computer can require as much as 120V at a maximum current draw of 5 amps, the maximum power the system can draw is about 550 watts. This wattage is for a system with every slot full, two hard disks, and one floppy in other words, a system at the maximum possible level of expansion. The system should never draw any more power than that; if it does, a 5-amp fuse in the power supply will blow. This type of system usually draws an average of 300 watts. However, to be safe when you make calculations for UPS capacity, be conservative; use the 550-watt figure. Adding a monitor that draws 100 watts brings the total to 650 watts or more. Therefore, to run two fully loaded systems, you'd need a 1,100-watt UPS. And don't forget two monitors, each drawing 100 watts. Therefore, the total is 1,300 watts. A UPS of that capacity or greater costs approximately \$500-\$700. Unfortunately, that is what the best level of protection costs. Most companies can justify this type of expense only for critical-use PCs, such as network servers.

Note

The highest-capacity UPS sold for use with a conventional 15-amp outlet is about 1,400 watts. If it's any higher, you risk tripping a 15-amp circuit when the battery is charging heavily and the inverter is drawing maximum current.

In addition to the total available output power (wattage), several other factors can distinguish one UPS from another. The addition of a ferroresonant transformer improves a unit's power conditioning and buffering capabilities. Good units also have an inverter that produces a true sine wave output; the cheaper ones might generate a square wave. A square wave is an approximation of a sine wave with abrupt up-and-down voltage transitions. The abrupt transitions of a square wave are not compatible with some computer equipment power supplies. Be sure that the UPS you purchase produces power that is compatible with your computer equipment. Every unit has a specification for how long it can sustain output at the rated level. If your systems draw less than the rated level, you have some additional time.

Caution

Be careful! Most UPS systems are not designed for you to sit and compute for hours through

an electrical blackout. They are designed to provide power only to essential components and to remain operating long enough to allow for an orderly shutdown. You pay a large amount for units that provide power for more than 15 minutes or so. At some point, it becomes more cost-effective to buy a generator than to keep investing in extended life for a UPS.

Some of the many sources of power protection equipment include American Power Conversion (APC) and Tripp Lite. These companies sell a variety of UPS, SPS, line, and surge protector products.

Caution

Don't connect a laser printer to a backed-up socket in any SPS or UPS unit. Such printers are electrically noisy and have widely varying current draws. This can be hard on the inverter in an SPS or a UPS and frequently cause the inverter to fail or detect an overload and shut down. Either case means that your system will lose power, too.

Printers are normally noncritical because whatever is being printed can be reprinted. Don't connect them to a UPS unless there's a good business need to do so.

Some UPSs and SPSs have sockets that are conditioned but not backed up that is, they do not draw power from the battery. In cases such as this, you can safely plug printers and other peripherals into these sockets.

RTC/NVRAM (CMOS RAM) Batteries

Most PCs have a special type of chip in them that combines a real-time clock (RTC) with at least 64 bytes (including 14 bytes of clock data) of nonvolatile RAM (NVRAM) memory. This chip is officially called the RTC/NVRAM chip, but it is often referred to as the CMOS or CMOS RAM chip because the type of chip used is produced using a CMOS (complementary metal-oxide semiconductor) process.

CMOS design chips are known for very low power consumption. This special RTC/NVRAM chip is designed to run off a battery for several years.

The original chip of this type was the Motorola MC146818, which was used in the IBM AT dating from August 1984. Although the chips used today have different manufacturers and part numbers, they all are designed to be compatible with this original Motorola part. Most modern motherboards have the RTC/NVRAM integrated in the motherboard chipset South Bridge or I/O Controller Hub (ICH) component, meaning no separate chip is required.

The function of the real-time clock should be obvious: The clock enables software to read the date and time and preserves the date and time data even when the system is powered off or unplugged. The NVRAM portion of the chip has another function: It is designed to store the basic system configuration, including the amount of memory installed, types of disk drives installed, Plug and Play device configuration, power-on passwords, and other information. Although some chips have been used that store up to 4KB or more of NVRAM, most motherboard chipsets with integrated RTC/NVRAM incorporate 256 bytes of NVRAM, of which the clock uses 14 bytes. The system reads this information every time you power it on.

Modern CMOS Batteries

Motherboard NVRAM (CMOS RAM) batteries come in many forms. Most are of a lithium design because they last 25 years or more. I have seen systems with conventional alkaline batteries mounted in a holder; these are much less desirable because they fail more frequently and do not last as long. Also, they are prone to leak, and if a battery leaks on the motherboard, the motherboard can be severely damaged. By far, the most commonly used battery for motherboards today is the coin cell, mounted in a holder that is part of the motherboard. Two main types of coin cells are used, differing in their chemistry. Most use a manganese dioxide (MnO₂) cathode, designated by a *CR* prefix in the part number; others use a carbon monofluoride (CF) cathode, designated by a *BR* prefix in the part number. The CR types are more plentiful (and thus easier to get) and offer slightly higher capacity. The BR types are useful for higher-temperature operation (above 60°C or 140°F).

Because the CR series is cheaper and easier to obtain, it is generally what you will find in a PC. The other digits in the battery part number indicate the physical size of the battery. For example, the most common type of lithium coin cell used in PCs is the CR2032, which is 20mm in diameter (about the size of a quarter) and 3.2mm thick and uses a manganese dioxide cathode. These are readily available at electronics supply stores, camera shops, and even drugstores. [Figure 19.40](#) shows a cutaway view of a CR2032 lithium coin cell battery.

Figure 19.40. Cutaway view of a CR2032 lithium coin cell.

[Table 19.23](#) lists the specifications of the common 20mm diameter lithium coin cell batteries you might find in a PC.

Table 19.23. Common 20mm Lithium Coin Cell Specifications

Type	Voltage (V)	Capacity (mAh)	Diameter (mm)	Height (mm)
BR2016	3.00	75	20.00	1.60
BR2020	3.00	100	20.00	2.00
BR2032	3.00	190	20.00	3.20
CR2012	3.00	55	20.00	1.20
CR2016	3.00	90	20.00	1.60
CR2025	3.00	165	20.00	2.50
CR2032	3.00	220	20.00	3.20

BR = Carbon monoflouride (CF) cathode
CR = Manganese dioxide (MnO2) cathode

Estimated battery life can be calculated by dividing the battery capacity by the average current required. For example, a typical CR2032 battery is rated 220 mAh (milliamp hours), and the RTC/NVRAM circuit in most current motherboard chipsets draws 5 µA (microamps) with the power off. Battery life can therefore

be calculated as follows:

- $220,000 \mu\text{Ah} \div 5 \mu\text{A} = 44,000 \text{ hours} = 5 \text{ years}$

If a thinner (and lower-capacity) battery such as the CR2025 is used, battery life will be shorter:

- $165,000 \mu\text{Ah} \div 5 \mu\text{A} = 33,000 \text{ hours} = 3.7 \text{ years}$

Battery life starts when the system is first assembled, which can be several months or more before you purchase the system, even if it is new. Also, the battery might be partially discharged before it is installed in the system; higher temperatures both in storage and in the system can contribute to shorter battery life. All these reasons and more can cause battery life to be less than what might be indicated by calculation.

As the battery drains, output voltage drops somewhat. Lower battery voltage can impair the accuracy of the RTC. Most lithium coin cell batteries are rated at 3V; however, actual readings on a new battery are usually higher. If your system clock seems inaccurate (it runs slow, for example), check the voltage on the CMOS battery. The highest accuracy is obtained if the battery voltage is maintained at 3.0V or higher. Lithium batteries normally maintain a fairly steady voltage until they are nearly fully discharged, whereupon the voltage quickly drops. If you check the battery voltage and find it is below 3.0V, consider replacing the battery, even if it is before the intended replacement time.

Obsolete or Unique CMOS Batteries

Although most modern systems use 3.0V coin cells, older systems have used a variety of battery types and voltages over the years. For example, some older systems have used 3.6V, 4.5V, and 6V types as well. If you are replacing the battery in an older machine, be sure your replacement is the same voltage as the one you removed from the system. Some motherboards can use batteries of several voltages, and you use a jumper or switch to select the various settings. If you suspect your motherboard has this capability, consult the documentation for instructions on changing the settings. Of course, the easiest thing to do is to replace the existing battery with another of the same type.

Some systems over the years have used a special type of chip that actually has the battery embedded within it. These are made by several companies, including Dallas Semiconductor and Benchmarq. These chips are notable for their long lives. Under normal conditions, the integral battery lasts for 10 years which is, of course, longer than the useful life of the system. If your system uses one of the Dallas or Benchmarq modules, the battery and chip must be replaced as a unit because they are integrated. Most of the time, these chip/battery combinations are installed in a socket on the motherboard just in case a problem requires an early replacement. You can get new modules directly from the manufacturers for \$18 or less, which is much more expensive than the coin-type lithium battery found in most modern systems. In fact, due to their expense and the fact that most motherboard chipset manufacturers have integrated the RTC/NVRAM functionality into the motherboard chipset, few if any modern PCs use these chip/battery modules.

Some systems do not use a battery at all. Hewlett-Packard, for example, includes a special capacitor in some of its systems that is automatically recharged anytime the system is plugged in. The system does not have to be running for the capacitor to charge; it only has to be plugged in. If the system is unplugged, the capacitor powers the RTC/NVRAM chip for up to a week or more. If the system remains unplugged for a duration longer than that, the NVRAM information is lost. In that case, these systems can reload the NVRAM from a backup kept in a special flash ROM chip contained on the motherboard. The only pieces of information that are actually missing when you repower the system are the date and time, which have to be reentered. By using the capacitor combined with an NVRAM backup in flash ROM, these systems have a very reliable solution that lasts indefinitely.

Many older systems use a separate battery that plugs in via a cable or that can even be directly soldered into the motherboard (mostly older, obsolete systems). For those older systems with the battery soldered in, a spare battery connector usually exists on the motherboard where you can insert a conventional plug-in battery if the original ever fails.

CMOS Battery Troubleshooting

Symptoms that indicate that the battery is about to fail include having to reset the clock on your PC every time you shut down the system (especially after moving it) and problems during the system's POST, such as drive-detection difficulties. If you experience problems such as these, you should make note of your system's CMOS settings and replace the battery as soon as possible.

Caution

When you replace a PC battery, be sure you get the polarity correct; otherwise, you will damage the RTC/NVRAM (CMOS) chip. Because the chip is soldered onto most motherboards, this can be an expensive mistake! The battery connector on the motherboard and the battery are usually keyed to prevent a backward connection. The pinout of this connector is on the disc, but it should also be listed in your system documentation.

When you replace a battery, in most cases the existing data stored in the NVRAM is lost. Sometimes, however, the data remains intact for several minutes (I have observed NVRAM retain information with no power for an hour or more), so if you make the battery swap quickly, the information in the NVRAM might be retained. Just to be sure, I recommend that you record all the system configuration settings stored in the NVRAM by your system Setup program. In most cases, you should run the BIOS Setup program and copy or print out all the screens showing the various settings. Some Setup programs offer the capability to save the NVRAM data to a file for later restoration if necessary.

Tip

If your system BIOS is password-protected and you forget the password, one possible way to bypass the block is to remove the battery for a few minutes and then replace it. This resets the BIOS to its default settings, removing the password protection.

After replacing a battery, power up the system and use the Setup program to check the date and time setting and any other data that was stored in the NVRAM.

Chapter 20. Building or Upgrading Systems

[System Components](#)

[Hardware and Software Resources](#)

[System Assembly and Disassembly](#)

[Motherboard Installation](#)

[Troubleshooting New Installations](#)

[Installing the Operating System](#)

[Disassembly/Upgrading Preparation](#)

System Components

In these days of commodity parts and component pricing, building your own system from scratch is no longer the daunting process it once was. Every component necessary to build a PC system is available off the shelf at competitive pricing. In many cases, the system you build can use the same or even better components than the top name-brand systems.

There are, however, some cautions to heed. The main thing to note is that you rarely save money when building your own system; purchasing a complete system from a mail-order vendor or mass merchandiser is almost always less expensive. The reason for this is simple: Most system vendors who build systems to order use many, if not all, of the same components you can use when building your own system. The difference is that they buy these components in quantity and receive a much larger discount than you can by purchasing only one of a particular item.

In addition, you pay only one shipping and handling charge when you purchase a complete system instead of the multiple shipping charges you pay when you purchase separate components. In fact, the shipping and handling charges from ordering all the separate parts needed to build a PC through the mail often add up to \$100 or more, and this doesn't count the additional time spent as well as additional telephone or Internet access charges accrued in the process. The cost rises if you encounter problems with any of the components and have to make additional calls or pay for shipping charges to send improper or malfunctioning parts back for replacement. Also, many companies charge restocking fees if you purchase something and then determine you don't need it or can't use it.

Finally, if you purchase parts locally, you typically must pay the additional state sales tax, as well as the higher prices usually associated with retail store sales.

Then there is the included software. Although I can sometimes come close in price to a commercial system when building my own from scratch, the bundled software really adds value to the commercial system. A copy of Windows XP costs \$100 or more, and many commercial systems also include Microsoft Office or other applications as well.

It is clear that the reasons for building a system from scratch often have less to do with saving money and more to do with the experience you gain and the results you achieve. In the end, you have a custom system that contains the exact components and features you have selected. Most of the time when you buy a preconfigured system, you have to compromise in some way. For example, you might get the video adapter you want, but you would prefer a different make or model of motherboard. By building your own system, you can select the exact components you want and build the ultimate system for your needs. The experience is also very rewarding. You know exactly how your system is constructed and configured because you have done it yourself. This makes future support and installation of additional accessories much easier.

Another benefit of building your own system is that you are guaranteed an industry-standard system that will be easily upgradeable in the future. Many of the larger system vendors use proprietary components that can make future upgrades difficult or impossible. Of course, if you have been reading the book up to this point, you already know everything you need to ensure any preassembled systems you purchase would use industry-standard components, and therefore be upgradeable and repairable in the future.

You might be able to save some money using components from your current system when building your new system. You might have recently upgraded your hard drive and optical drive in an attempt to extend

the life of your current computer. In most cases, you can take those components with you to the new system. For example, if you bought a 120GB hard drive and a DVD+/-RW drive for your old system, you can move them to a newer system.

Your monitor, keyboard, mouse, storage devices, most PCI adapter cards, and some AGP video cards from your old system will likely work in your new system. The bad news is that most newer systems require different memory from an older system and most older AGP 1X or 2X video cards often do not work in newer motherboards with 4X or 8X slots or in motherboards that utilize the newer PCI Express slot for the video card.

So, if you are interested in a rewarding experience, want a customized and fully upgradeable system that is not exactly the same as that offered by any vendor, are able to take on all system repair and troubleshooting tasks, want to save some money by reusing some of the components from your current system, and are not in a hurry, building your own PC might be the way to go.

On the other hand, if you are interested in getting a PC with the most value for the best price, want one-stop support for in-warranty repairs and technical problems, and need an operational system quickly, building your own system should be avoided. In that case, you should consider purchasing a system from a name-brand vendor. Also, if you are unable to provide self-support or will not be upgrading the system, you might consider an extended warranty. An extended warranty essentially prevents you from doing any upgrades to the system because an upgrade is not covered and, in some cases, can even invalidate the warranty on the rest of the system. If you do plan to upgrade your system after a year or so of use, you should avoid purchasing any extended warranties.

This chapter details the components necessary to assemble your own system, explains the assembly procedures, and lists some recommendations for components and their sources.

The components used in building a typical PC are as follows:

- Case and power supply
- Motherboard
- Processor with heatsink and fan
- Memory
- Floppy drive (optional)
- Hard disk drive
- Optical drive(s) (CD and/or DVD)
- Keyboard and pointing device (mouse)
- Video card and display
- Sound card (optional) and speakers
- Modem (optional) or network interface card (optional)
- Cables
- Hardware (nuts, bolts, screws, and brackets)
- Operating system software

Each of these components is discussed in the following sections. However, before you buy anything, you should keep in mind that support for audio, Ethernet, video, and so on is often built in to the motherboard.

Case and Power Supply

The case and power supply are typically sold as a unit, although some vendors do sell them separately even when sold together, you might want to replace the existing PSU with one of your choosing. There are a multitude of designs from which to choose, usually dependent on the motherboard form factor you want to

use, the number of drive bays available, and whether the system is desktop or floor mounted. There are cases with extra fans for cooling (recommended), air filters on the air inlets to keep out the dust, removable side panels, or motherboard trays; cases that require no tools for assembly, rack-mounted versions, and more. For most custom-built systems, a mid-tower case supporting ATX form factor motherboards and ATX12V form factor power supplies is the recommended choice. The size and shape of a component is called the *form factor*. The most popular case form factors are as follows:

- Full-tower
- Mid- or mini-tower
- Desktop
- Low-profile (also called Slimline)

Each specific case is designed to accept a specific motherboard and power supply form factor as well. You have to ensure that the particular case you choose will accept the type of motherboard and power supply you want to use.

When deciding which type of case to purchase, you should consider where you will place your computer. Will it be on a desk? Or is it more feasible to put the system on the floor and just have the monitor, keyboard, and mouse on the desk? The amount of space you have available for the computer can affect other purchasing decisions, such as the length of the monitor, keyboard, and mouse cables.

After you have settled on a case form factor, you need to choose one that supports the motherboard and power supply form factors you want to use. The smaller mini-tower or slimline cases often accept only MicroATX, FlexATX, MicroBTX, or PicoBTX motherboards, which somewhat limit your choices. If the case you choose fits a full-size ATX board, you can be sure it also accepts the smaller MicroATX and FlexATX boards. The same is true for BTX: A chassis that can handle BTX also accepts MicroBTX and PicoBTX. FlexATX (and variations such as MiniITX) and PicoBTX motherboards are used in some of the latest small form factor systems.

◀◀ See "[Motherboard Form Factors](#)," p. [216](#).

Most mid-tower and larger cases accept full-size ATX boards, which have become the standard for most full-function systems. If you are interested in the most flexible type of case and power supply that will support the widest variety of future upgrades, I recommend getting a chassis that supports full-size ATX boards and ATX12V power supplies.

Important Considerations

Generally, any ATX case, motherboard, and power supply of sufficient wattage for your equipment can be put together to form the basis of a new system. However, there are two major exceptions you need to know about:

- Many Dell systems built from 1996 through 2000 use nonstandard motherboards and power supplies with what appears to be a standard ATX power supply physical connector; however, the pinout and voltage levels have changed. If you mix a nonstandard Dell motherboard and a standard ATX power supply, or a standard ATX motherboard and a nonstandard Dell power supply, you will destroy the power supply and possibly your motherboard as well! If you want to upgrade newer Dell systems, you must either buy Dell-compatible power supplies for use with the Dell motherboard or replace both Dell components with standard ATX components. Refer to [Chapter 19](#), "Power Supplies," for more details. Many of Dell's newer systems also use nonstandard power supplies and motherboards, but these are more obvious in that they do not use standard connectors either, which means a standard ATX motherboard or power supply will not physically plug in. This makes an upgrade difficult or impossible, but at least you won't blow up any hardware in the process.
- Intel Pentium 4 (and newer) and AMD Athlon (and newer) CPUs require heavy heatsinks and fans for cooling. Be sure to use a heatsink designed for your particular processor, and make sure it is properly installed. These high-powered systems also require an ATX12V power supply, which has an additional 12V connector for the motherboard-based CPU voltage regulators. ATX12V adapters are available to convert standard ATX power supplies, but in general you should upgrade to an ATX12V supply that has upgraded internal circuitry and wiring to handle the additional 12V power required.

Whether you choose a desktop or one of the tower cases is really a matter of personal preference and system location. Most people feel that the tower systems are roomier and easier to work on, and the full-sized tower cases have a lot of bays for various storage devices. Tower cases typically have enough bays to hold floppy drives, multiple hard disk drives, optical drives, tape drives, and anything else you might want to install. However, some of the desktop cases can have as much room as the towers, particularly the mini- or mid-tower models. In fact, a tower case is sometimes considered a desktop case turned sideways or vice versa. Some cases are convertible—that is, they can be used in either a desktop or tower orientation.

Tip

Mini-tower systems are an exception to the roomy tower case rule. These systems normally use the MicroATX, FlexATX, MicroBTX, or PicoBTX motherboards and might have only two or three drive bays. These systems are compact and somewhat difficult to work on. These systems are, however, easily picked up and moved from one location to another.

When it comes to the power supply, the most important consideration is how many devices you plan to install in the system and how much power they require. [Chapter 19](#) describes the process for calculating

the power your system hardware requires and selecting an appropriate power supply for your needs.

◀◀ See "[Power-Use Calculations](#)," p. [1196](#).

When you build your own system, you should always keep upgradeability and repairability in mind. A properly designed custom PC should last you far longer than an off-the-shelf model because you can more easily add or replace components. When choosing a case and power supply, leave yourself some room for expansion, on the assumption that you will eventually want to install an additional hard drive or some other new device that appears on the market that you can't live without. To be specific, be sure you have at least two empty internal drive bays and choose a higher output power supply than you need for your current equipment, so it won't be overtaxed when additional components are added later.

Processor

Both Intel and AMD sell processors through two primary channels or methods. They are referred to as *boxed* (or retail) and *OEM*.

A boxed processor and an OEM processor might have the same specifications, but they are packaged differently, include different supplemental components, and have different warranties. Even though the boxed processors are sometimes also called *retail* processors, they are technically not intended to be sold in the normal retail channel. Both boxed and OEM processors are technically wholesale items and, as such, can be purchased from Intel or AMD only by signing up as a dealer with them and meeting their requirements to achieve and maintain dealer status. After you are registered as an Intel or AMD dealer, you can purchase boxed processors directly from them.

OEM processors are sold only to major accounts that purchase hundreds of chips at a time. Although neither the boxed nor OEM processors are intended to be sold in the retail channel, after Intel or AMD sells them to one of their dealers, that dealer is free to resell the chips as he chooses. Therefore, an individual can purchase either boxed or OEM processors from many sources.

The most obvious difference between the boxed and OEM processors is the physical packaging. It could be argued that both technically come in boxes, but the Intel or AMD *boxed* processors come individually packaged in a colorful shrink-wrapped box that includes the processor, the heatsink and fan, installation instructions, a certificate of authenticity, warranty paperwork, and so on (see [Figure 20.1](#)).

Figure 20.1. Boxed Intel Pentium 4 Extreme Edition. *Photo used by permission of Intel Corporation.*

On the other hand, OEM processors come in a much larger box with multiple trays containing up to 10 processors each, or up to 100 total. No heatsinks, fans, installation instructions, warranties, or other paperwork are included. These are purchased in large quantities by the major system manufacturers.

A boxed processor generally includes a 3-year warranty direct with the processor manufacturer. So, if the CPU fails within 3 years of purchase, the end user can contact Intel or AMD directly and they will replace the chip. OEM processors have *no* warranty with the manufacturer (Intel or AMD); however, the company from which you purchased it will likely offer a 30- or 90-day warranty. The warranty length and the way in which it is administered are entirely up to the dealer from which you purchased the chip, which could be a problem if, for example, that dealer has gone out of business.

Boxed processors also include a high-quality, manufacturer-supplied heatsink and cooling fan. Typically, the cooling system provided with a boxed processor is designed to work under worst-case thermal environments and is a very high-quality and heavy-duty unit. When you think about it, it wouldn't serve Intel or AMD to provide cheap heatsinks and fans on a processor they are warranting for 3 years!

OEM processors, on the other hand, include no heatsink or fan, but the dealer from which you purchase the processor will likely provide one. Unfortunately, these are often of very uneven quality and performance, up to the whims of the particular dealer you are using. With only a 30- or 90-day warranty, it doesn't matter as much if the manufacturer skimps on the heatsink because, if the chip fails beyond the short warranty period, the company isn't obligated to replace it. If you purchase an OEM processor with a motherboard, most dealers install the processor into the motherboard and provide a single warranty covering both items.

The motherboards you consider should have one of the following processor sockets or slots:

- *Socket 775*. Supports the third-generation Intel Pentium 4 processors, including the newer Pentium 4 EE (Extreme Edition), Pentium D, and Pentium 4 E
- *Socket 939*. Supports the second-generation Athlon 64 FX processors, including the newer Athlon 64 X2
- *Socket 940*. Supports the original Athlon 64 FX processors
- *Socket 754*. Supports the Athlon 64 processors

The following socket types also can be purchased but are not compatible with the latest CPU models and will limit your future processor upgrade options:

- *Socket 478*. Supports the second- and third-generation Intel Pentium 4 and compatible Celeron processors
- *Socket A (462)*. Supports the AMD Athlon, Athlon XP, and Duron processors
- *Socket 370 (also called PGA370)*. Supports the PGA versions of the Intel Pentium III and compatible Celeron processors

Because the motherboard you choose dictates or limits your choice in processor, you should choose your processor first, which will then dictate the type of CPU socket (or slot) that must be present. For more information on processors, refer to [Chapter 3](#), "Microprocessor Types and Specifications."

◀◀ See "[Processor Socket and Slot Types](#)," p. [87](#).

Depending on the type of motherboard you select, there might be jumpers on the motherboard to set for processor type and speed. It also might have jumpers to control the voltage supplied to the processor. Typically, older Socket 7 or Super7 boards have jumpers for motherboard bus speed, CPU multiplier, and CPU voltage settings. If you purchase this type of board, be sure you get these settings correct; otherwise, the system won't run properly. In a worst-case situation, you can damage the processor with too high a voltage setting, for example.

All modern processor sockets handle these settings automatically, so there is little danger of incorrect settings. Even so, several boards have overrides for the automatic settings, which can be useful for those intending to hotrod or overclock their processors. Most of these boards use the BIOS Setup to control these overrides, so no jumpers or switches need to be set.

Tip

A useful cross-reference of all modern Pentium and Athlon CPUs can be found at the Tom's Hardware website: www.tomshardware.com. The charts change fairly often, so you should search within the CPU section of the site.

Motherboard

Several compatible form factors are used for motherboards. The form factor refers to the physical dimensions and size of the board and dictates into which type of case the board will fit. The types of compatible industry-standard motherboard form factors generally available for system builders are as follows:

Modern form factors

- BTX
- ATX
- MicroATX
- FlexATX
- NLX
- MiniITX (semiproprietary)

All others

- Proprietary designs (some Compaq, Dell Optiplex, Hewlett-Packard, notebook/portable systems, and so on); many Dell Dimension systems from 1996 through 2000 use ATX form factors, but with different electrical pinouts; newer Dell Dimension and Dimension XPS systems use proprietary motherboards and power supplies as well.

BTX is the latest form factor, designed as an improved replacement for ATX; however, BTX is not physically compatible with and requires a different chassis from ATX. Because BTX was designed in part to help reduce the effects of hotter and hotter-running processors by better controlling airflow through the chassis, the recent trend in CPU design of increasing performance through design efficiency rather than ramp-ups in pure clock speed has diminished the need for it. Consequently, ATX has remained the dominant form factor for PCs and is likely to remain so for some time.

Note

For more information on all the motherboard form factors, refer to [Chapter 4](#), "Motherboards and Buses." You can also find the reference standard documents detailing the modern form factors at the Desktop Form Factors website: <http://www.formfactors.org>.

In addition to processor support and form factor, you should consider several other features when selecting a motherboard. The following sections examine each feature.

Chipsets

Aside from the processor, the main component on a motherboard is called the *chipset*. This usually is a set of one to five chips that contains the main motherboard circuits. These chipsets replace the 150 or more distinct components that were used in the original IBM AT systems and enable a motherboard designer to easily create a functional system from just a few parts. The chipset contains all the motherboard circuitry except the processor and memory in most systems.

Because the chipset really *is* the motherboard, the chipset used in a given motherboard has a profound effect on the performance of the board. It dictates all the performance parameters and limitations of the board, such as memory size and speed, processor types and speeds, supported buses and their speeds, and more. If you plan to incorporate technologies such as the Accelerated Graphics Port (AGP) or the Universal Serial Bus (USB) into your system, you must ensure that your motherboard has a chipset that supports these features.

Because chipsets are constantly being introduced and improved over time, I can't list all of them and their functions here; however, you will find a detailed description of many of them in [Chapter 4](#). Several popular high-performance chipsets are on the market today.

◀◀ See "[Chipsets](#)," p. [253](#).

◀◀ See "[Motherboard Selection Criteria \(Knowing What to Look For\)](#)," p. [405](#).

Clearly, the selection of a chipset must be based largely on the processor you choose and the additional components you intend to install in the computer.

However, no matter which chipset you look for, I recommend checking the following supported features to ensure they match your needs and desires:

- CPU bus speed support
- The type of main memory supported
- AGP8X or PCI Express video support
- Serial ATA interfaces (or both serial and parallel)
- USB 2.0 (high-speed USB) support
- Support for the fastest available processor in the processor family you choose, even if you are installing a slower model

If you are intent on building the ultimate PC (at least by this week's standards), you also should consider the faster processors available. Be sure not to waste your investment on the most capable processor by using a chipset that doesn't fully exploit its capabilities.

When you are designing your system, carefully consider the number and type of expansion cards you intend to install. Then, ensure that the motherboard you select has the correct number of slots and that they are of the correct bus type for your peripherals (PCI, AGP, and PCI Express). Because most recent boards lack ISA slots, if you have any ISA peripherals, it is long past time that you replace them with more capable PCI or PCI Express versions.

When you buy a motherboard, I highly recommend you contact the chipset manufacturer and obtain the documentation (often called the *data book*) for your particular chipset. This explains how the memory and cache controllers, as well as many other devices in the system, operate. This documentation should also

describe the Advanced Chipset Setup functions in your system's Setup program. With this information, you might be able to fine-tune the motherboard configuration by altering the chipset features. Because chipsets are frequently discontinued and replaced with newer models, don't wait too long to get the chipset documentation because most manufacturers make it available only for chips currently in production.

Note

One interesting fact about chipsets is that in the volume that the motherboard manufacturers purchase them, the chipsets usually cost about \$40 each. If you have an older motherboard that needs repair, you usually can't purchase the chipsets because they aren't stocked by the manufacturer after they are discontinued. Not to mention that most chipsets feature surface mounting with ball grid array (BGA) packages that are extremely difficult to manually remove and replace. The lowcost chipset is one of the reasons motherboards have become disposable items that are rarely, if ever, repaired.

BIOS

Another important feature on the motherboard is the basic input/output system (BIOS). This is also called the ROM BIOS because the code is stored in a read-only memory (ROM) chip. There are several things to look for here. One is that the BIOS is supplied by one of the major BIOS manufacturers, such as AMI (American Megatrends International), Phoenix, or Award (owned by Phoenix). Also, be sure that the BIOS is contained in a special type of reprogrammable chip called a Flash ROM or EEPROM (electrically erasable programmable read-only memory). This enables you to download BIOS updates from the manufacturer and, using a program it supplies, easily update the code in your BIOS. If you do not have the Flash ROM or EEPROM type, you must physically replace the chip if an update is required.

See "[Upgrading the BIOS](#)," p. [429](#).

Virtually all motherboards built in the last few years include a BIOS with support for the Plug and Play (PnP) specification. This makes installing new cards, especially PnP cards, much easier. PnP automates the installation and uses special software built in to the BIOS and the operating system (such as Windows 9x/Me and Windows 2000/XP) to automatically configure adapter cards and resolve adapter resource conflicts.

You also need to verify that the BIOS supports both the processor you plan to install initially and the processor you might upgrade to in the future. If the motherboard and chipset can handle a new processor but the BIOS cannot, a BIOS upgrade can be used to provide proper support.

Note

For more information on PnP, refer to "Plug and Play BIOS" in [Chapter 5](#), "BIOS." Also, an exhaustive listing of PnP device IDs can be found in the Technical Reference section of the disc included with this book.

Memory

Older systems had L2 cache memory on the motherboard, but for almost all systems starting with the Pentium II, this cache is a part of the processor. The few remaining Socket 7 or Super7 motherboards do still include cache onboard, and it is normally soldered in and not removable or upgradeable.

◀◀ See "[Cache Memory: SRAM](#)," p. [476](#).

Main memory typically is installed in the form of dual inline memory modules (DIMMs). Three physical types of main memory modules are commonly used in PC systems today, with several variations of each. The main types are as follows:

- 168-pin SDRAM DIMMs
- 184-pin DDR DIMMs
- 240-pin DDR2 DIMMs

The 168-pin SDRAM DIMMs are found only in older or lower-end systems today. DIMMs have become popular because they are 64 bits wide and can be used as a single bank on a Pentium or higher-class processor that has a 64-bit external data bus.

Double data rate (DDR) SDRAM memory is a newer variation on SDRAM in which data is transferred twice as quickly, and it is the most common type of memory used in recent systems. DDR2 DIMMs came out in new systems during 2004 and are fast becoming the most common type of memory in new systems.

Note

Memory modules using Rambus DRAM, which used proprietary Rambus memory modules called RIMMs, were used in a limited number of systems from 1999 through 2002 but have since been phased out. Although both DDR DIMMs and RDRAM RIMMs use 184-pin connectors, their pin configurations are completely different and the modules are *not* interchangeable.

◀◀ See "[DDR SDRAM](#)," p. [486](#).

Current systems using a 64-bit CPU bus require a single DIMM (64 bits wide) to make a single bank. Systems using DDR or DDR2 DIMMs can also use dual-channel memory, in which pairs of matching DIMMs enable double the memory throughput.

Memory modules can include an extra bit for each 8 for parity checking or ECC use. If ECC is important to you, be sure your chipset (and motherboard) supports ECC before purchasing the more expensive ECC modules.

◀◀ See "[Parity and ECC](#)," p. [514](#).

For more information on PC memory of all types, including added detail on RIMM and SIMM modules, refer to [Chapter 6](#), "Memory."

I/O Ports

Virtually all motherboards today have built-in I/O ports. In rare cases where these ports are not built in, they must be supplied via a plug-in expansion board that, unfortunately, wastes an expansion slot. The following ports might be included in any new system you assemble:

- PS/2 Keyboard connector (mini-DIN type)
- PS/2 Mouse port (mini-DIN type)
- One or two serial ports
- Parallel port
- Four or more USB ports
- Two or more FireWire ports
- One or two analog VGA or DVI video connectors (integrated video)
- RJ-45 port for 10/100 or 10/100/1000 Ethernet
- Audio connectors (speakers, microphone, and so on)
- Two or more serial ATA ports

Some motherboards lack the serial, parallel, keyboard, and mouse ports (referred to as legacy ports), instead relying on USB for those connections. You might want to avoid "legacy-free" motherboards if you still use peripherals with those types of connections. Most motherboards feature integrated sound, and many have optional integrated video as well.

All the integrated ports are supported either directly by the motherboard chipset or by an additional Super I/O chip and additional interface components. Adding the optional video and sound interfaces directly to the motherboard saves both money and the use of an expansion slot, especially important in the less expensive systems sold today. In the case of integrated video, however, you're likely to incur a performance hit as compared to having a separate AGP or PCI Express video card.

If these devices are not present on the motherboard, various Super I/O or multi-I/O boards that implement all these ports are available. Again, most of the newer versions of these boards use a single-chip implementation because it is cheaper and more reliable.

◀◀ See "[Super I/O Chips](#)," p. [342](#).

The primary drawback of having functions such as video and networking built in to the motherboard, of course, is that you have little or no choice about the features or quality of the integrated adapters. Integrated components such as these are nearly always of serviceable quality, but they certainly do not push the performance envelope of higher-end expansion cards. Most people who decide to build a system themselves do so because they want optimum performance from every component, which you typically do not get from integrated video and sound.

Buying a motherboard with integrated adapters, however, does not preclude you from adding expansion devices of the same type. You usually can install a video or sound card into a system with an integrated sound or video adapter without major problems, except that the additional cost of the integrated component is wasted. You also might encounter difficulties with the automated hardware detection routines

in operating systems such as Windows 9x/Me/2000/XP detecting the wrong adapter in your system, but you can remedy this by manually identifying the expansion card to the OS. If you want the convenience of integrated video but want to maintain the option of installing a faster PCI Express video card later, look for systems that provide both integrated video and the required slot you'll need for your video card.

◀◀ See "[Integrated Video/Motherboard Chipsets](#)," p. [888](#); "[Intel 845 Family](#)," p. [286](#); and "[Intel 865 Family](#)," p. [288](#).

If four or more USB ports exist, they often are split among two or more buses, with one set of connections on the back of the board and another set as a pin-header connector on the motherboard. A cable then plugs in to this connector, enabling you to route the second USB bus port to the front of the PC case. Most newer cases have provisions for front-mounted USB ports in this manner, which makes temporarily connecting devices such as digital cameras or MP3 players for transferring files easier. Even though USB 2.0 support is increasingly common, some systems use a separate USB 2.0 support chip; therefore, some USB ports on such systems support only the older USB 1.1 standard. Also, you might need to enable USB 2.0 support in the system BIOS and load USB 2.0 drivers before USB 2.0 ports will support USB 2.0 devices at top speed.

Note that if your motherboard has integrated devices such as video and sound, you must go into the BIOS Setup to disable these devices if you want to add a card-based replacement device. Check your BIOS Setup menus for an Enable/Disable setting for any integrated devices.

Hard Disk Drives

Your system also needs at least one hard disk drive. In most cases, a drive with a minimum capacity of 80GB is recommended, although in some cases you can get away with less for a low-end configuration. High-end systems should have drives of 300GB or higher. One of the cardinal rules of computer shopping is that you can never have too much storage. Buy as much as you can afford, and you'll almost certainly end up filling it anyway.

Tip

If you are an Internet user, one informal method of estimating how much disk space you will need is to go by the speed of your Internet connection. If you have a high-speed link, such as that provided by a DSL connection, a cable modem, or a LAN, you will find that the ease of downloading large amounts of data fills disk drives amazingly quickly. I would recommend at least a 120GB hard drive in these cases. In addition, a removable storage system with a large capacity, such as a dual-layer DVD+/-RW drive, is also a good idea.

Note that Windows 95 does not support any drives larger than 32GB. You should upgrade to at least Windows 98 or 2000, although at this point I recommend taking the leap to Windows XP or even Windows Vista after its release in late 2006.

For the time being, the most common hard drive interface for desktop systems is still parallel ATA, although serial ATA is becoming more popular and will likely be the only widely available choice in the next year or two.

Some of the newest motherboards now feature RAID-compatible ATA or SATA interfaces. These enable you to install two identical IDE drives (a pair of 80GB drives, for example) and treat them as a single very large and very fast 160GB hard drive.

Most new motherboards now feature Serial ATA (SATA) interfaces, many of which are also RAID compatible. Although the SATA drive interface is technically faster than the fastest ATA interface on the market (ATA-133), real-world SATA drive performance is currently on par with ATA drive performance because both are limited by the throughput of the drive mechanism and media. However, if your motherboard supports SATA, the smaller cable size used for data and the promise of higher performance in the future can still make using SATA drives a better choice.

Most systems have USB 2.0, and more and more systems have IEEE 1394 (FireWire) built in to the motherboard or added as PCI expansion cards. Although FireWire and USB 2.0-based drives have performance similar to ATA drives and can be moved from system to system, they are not recommended as primary drives. However, they can be used for additional portable storage or system backup.

◀◀ See "[ATA RAID](#)," p. [596](#), and "[Serial ATA](#)," p. [569](#).

Several brands of high-quality hard disk drives are available from which to choose, and most offer similar performance within their price and capacity categories. In fact, you might notice that the capacities and specifications of the various ATA and SATA drives certain manufacturers offer are remarkably similar. This is because a single drive assembly is manufactured for use with both interfaces.

Removable Storage

Despite diminishing usage, the floppy disk drive has remained a mainstay component of PCs for more than 20 years (counting both 5 1/4" and 3 1/2" floppy drives, of course). However, since the advent of the CD-RW, the floppy disk drive has largely been relegated to a minor role as an alternative system boot device. Many of today's systems are no longer equipped with a 1.44MB 3 1/2" drive because all systems today are capable of booting from CD, thus making CD-R or CD-RW discs a useful high-capacity replacement for floppy or Zip drives.

However, for additional removable storage, I recommend a DVD+/-RW (DVD-rewriteable) drive over floppy, Zip, or even CD-RW, regardless of your budget. These are now relatively inexpensive—often well under \$100—and they allow you to use your choice of optical media, be it CD or DVD. Rewritable DVD media prices have also dropped considerably in recent years, making the cost per megabyte of storage superior to using rewritable CD media. Rewritable CDs store just 700MB of data compared to 4.7GB for a single-layer DVD+/-RW disc. And if your DVD+/-RW drive of choice can also burn to dual-layer discs, that storage capacity is doubled. (Bear in mind, though, that dual-layer DVD media is considerably more expensive at this time.)

◀◀ See "[DVD](#)," p. [738](#).

Regardless of format, some form of optical drive is considered a mandatory item in any PC you construct if for no other reason than because almost all software is now distributed on CD-ROM or DVD. That said, while the increasingly affordable rewritable DVD drive should be considered a required component in any new PC, an external hard drive is also worth considering if you need extra removable storage either for

portability or for data backups. Even a dual-layer DVD cannot match the storage capacity of today's external hard drives, which can hold upwards of 400GB of data. Smaller 100GB drives that include USB 2.0 or FireWire ports (sometimes both) can now be had for around \$100, and many of them include software that allows you to configure so-called "one-button backups" that let you simply press a button on the external drive and automatically back up your essential data.

On a smaller scale, USB-driven flash memory drives provide a much more compact storage solution that can be carried with you wherever you go. The first generation of flash drives often stored as little as 16MB of data, but today's larger devices can hold in excess of 1GB of data.

Input Devices

Obviously, your system needs a keyboard and some type of pointing device, such as a mouse. Different people prefer different types of keyboards, and the "feel" of one type can vary considerably from other types. If possible, I suggest you try a variety of keyboards until you find the type that suits you best. I prefer a stiff action with tactile feedback myself, but others prefer a lighter, quieter touch.

Keyboards and mice typically include connectors that can accommodate either PS/2 or USB ports. Even though PS/2 versions that plug in to a 6-pin mini-DIN (PS/2) connector have traditionally been the most popular, USB has all but supplanted them at this point on newer systems. Wireless keyboards and mice, such as Logitech's G7 laser mouse, often have no support at all for the venerable PS/2 port.

Though rarely an issue in new systems, it's important to keep in mind that, with any USB device, you must have support in the operating system for USB, and in the case of USB keyboards and mice, your system BIOS must support a function called Legacy USB or USB Keyboard and Mouse if you want to use the USB keyboard or mouse outside the Windows graphical user interface. Virtually all recent BIOSs have this feature. However, to enable you to use your USB keyboard or mouse on both new and older systems, I recommend you look for models that also support the traditional PS/2 ports. This type usually ships with a USB-to-PS/2 adapter. These adapters can also be purchased separately if necessary.

If you prefer a wireless keyboard or mouse, it used to be important that you chose one that uses RF (radio) instead of IR (infrared) signaling and one that could use a single transceiver for both the keyboard and mouse. In current products, that choice is largely made for you. However, you should keep in mind that RF signaling might use either short-range proprietary frequencies or the industry-standard Bluetooth wireless network architecture. Bluetooth devices are preferable if you want to use the keyboard or mouse with a wide variety of devices or at distances greater than 6 feet or so from the system.

◀◀ See "[Keyboards](#)," p. [1012](#).

◀◀ See "[Keyboard Technology](#)," p. [1016](#).

Tip

You might be tempted to skimp on your keyboard and mouse to save a few dollars. Don't! You do all your interacting with your new PC through these devices, and cheap ones make their presence known every time you use your system. I insist on high-quality mechanical switchtype keyboards on all my systems.

The success of USB has changed the market so that there are virtually no limits to the types of devices available that can make use of the connection. Modems, keyboards, mice, optical drives, speakers, joysticks, hard drives, tape drives, floppy drives, scanners, cameras, MP3 players, and printers are just some of the devices available. However, before you start buying all USB peripherals for your new system, if your system supports only USB 1.1, you should be aware that performance problems can occur with some devices if used on a single bus, and sometimes compatibility problems can occur as well. USB 2.0 (also called High-Speed USB), which is standard for almost all new and recent motherboards, solves these problems.

◀◀ See "[USB Keyboards](#)," p. [1027](#).

Video Card and Display

You need a video adapter and a monitor or display to complete your system. Numerous choices are available in this area, but the most important piece of advice I have to give is to choose a good monitor. The display is your main interface to the system and can be the cause of many hours of either pain or pleasure, depending on which monitor you choose. As has been the case for several years, the first choice you need to make in a display is whether to purchase a CRT or an LCD.

I usually recommend a minimum of a 19" CRT display these days (equivalent to a 17" LCD display). 17" CRTs are very usable as well, but anything smaller can't acceptably display a 1024x768 pixel resolution, which is really the minimum acceptable resolution for today's systems. If you opt for a 15" or smaller CRT display, you might find that the maximum tolerable resolution is 800x600. This might sound confusing because many 15" monitors are capable of displaying 1024x768 resolution or even higher, but the characters and features are so small onscreen at that resolution that excessive eyestrain and headaches are often the result; the display often is blurry when a monitor is run at its maximum resolution. If you spend a lot of time in front of your system and want to work in the higher screen resolutions, a 17" CRT display should be considered a mandatory minimum. However, because there is very little extra cost involved, I recommend a 19" CRT display; they work even better at the higher resolutions and have come down in price considerably from previous years. Look for CRT displays with lower dot pitch (0.28dpi or less), which indicates the size and spacing of dots in the CRT mask. Lower means higher resolution and a clearer picture.

If your desk space is limited or you don't mind paying more money per screen inch, consider the wide variety of flat-screen LCD panels now available (a 15" LCD panel is about equal in viewable area to a 17" CRT). In most cases they can be attached to a VGA analog port, but the most current models are designed to work with the DVI connector, which is rapidly becoming the default connector type on modern video cards. LCD panels are an excellent choice if you always use the native resolution (typically 1024x768 on 15" displays or 1280x1024 on 17" displays), but if you need to change resolutions (for previewing web page designs or game playing), CRTs are better.

Your video card and monitor should be compatible in terms of refresh rate. The minimum refresh rate for a solid, nonflickering CRT display is 70Hz/72Hz (the higher, the better). If your new video card can display 32-bit color at a resolution of 1280x1024 and a refresh rate of 75Hz, but your monitor's maximum refresh rate at 1280x1024 is 60Hz, you can't use the video card to its maximum potential. Configuring a video adapter to deliver signals the monitor can't support is one of the few software configuration processes that can physically damage the system hardware. Pushing a monitor beyond its capabilities can cause it irreparable harm. Note that LCD displays don't flicker, regardless of the refresh rate.

In the past few years, video adapters had become standardized on the accelerated graphics port (AGP) interface. Today, however, many video cards especially high-performance cards have made the leap to PCI Express. In some cases you will find graphics cards based on PCI as well. The only instance in which a PCI graphics card should be used in a desktop system is if you are adding a secondary video adapter for use with a second video display. Windows 98, Me, 2000, and XP support multiple monitors on a single system, and it's a feature that can be very useful for a variety of applications. If performance is your ultimate goal and you can tolerate the added expense, look for a system that supports dual PCI Express x16 graphics cards. Both NVIDIA and ATI offer high-performance video chipsets that can be used to run dual video cards together to increase video display performance.

◀◀ See "[Accelerated Graphics Port](#)," p. [378](#).

◀◀ See "[3D Graphics Accelerators](#)," p. [908](#).

If you are installing a newer video card as a replacement upgrade to your current system, you can remove the existing video card and replace it with any video card that supports the motherboard's standard (be it AGP or PCI Express). In the case of older systems using AGP, you should ensure that the AGP slot and card are compatible because AGP has been implemented in multiple versions based on speed (4x, 8x, and so on). You can also replace an existing PCI video card with another PCI video card if there is no AGP slot, but you should consider a system upgrade instead to provide an AGP or a PCI Express slot for faster video.

Many motherboards with onboard video also have an AGP or a PCI Express slot; if your motherboard has one, you can insert the applicable card into this slot. The onboard video should be automatically disabled in most cases, although you might have to disable it in the system BIOS instead.

Audio Hardware

All systems today should be capable of playing audio to some degree, which means you need at least a passable set of external speakers and either a motherboard with integrated audio or a separate sound card. Most systems today, even those without integrated video, now feature integrated audio, but it can be disabled if you prefer to add a dedicated high-quality sound card. Dedicated cards, such as Creative's X-Fi product line, are ideal if you want the best possible sound quality for DVD playback, audio capture and editing, or surround sound for gaming. Almost any motherboard-integrated audio system and sound card on the market today are compatible with the baseline Creative Sound Blaster series, Windows DirectSound, and other sound APIs. Virtually all dedicated sound cards are based on PCI, although you might be able to find older ISA cards if you look hard enough.

Caution

If you run older DOS-based games or applications, you need to keep in mind that today's audio chipsets (especially when used in a modern OS such as Windows XP) often fail to process audio. In some cases audio playback is spotty; in others it either fails entirely or causes the program itself not to run.

Speakers designed for use with PCs range from tiny, underpowered devices to large audiophile systems. Many of the top manufacturers of stereo speakers now produce speaker systems for PCs. Some include subwoofers or even a full Dolby 5.1, 6.1, or 7.1 surround sound implementation.

Accessories

Apart from the major components, you need several other accessories to complete your system. These are the small parts that can make the assembly process a pleasure or a chore. If you are purchasing your system components from mail-order sources, you should make a complete list of all the parts you need, right down to the last cable and screw, and be sure you have everything before you begin the assembly process. It is excruciating to have to wait several days with a half-assembled system for the delivery of a forgotten part.

Heatsinks/Cooling Fans

Most of today's faster processors produce a lot of heat, and this heat has to be dissipated so your system doesn't operate intermittently or even fail completely. Heatsinks are available in two main types: passive and active.

Passive heatsinks are simply finned chunks of metal (usually aluminum or copper) that are clipped or glued to the top of the processor. They act as a radiator and, in effect, give the processor more surface area to dissipate the heat. *Active* heatsinks, which include the heatsink itself and an attached fan, are required by most processors today because of their higher capacity and smaller space requirements. Often you have no control over which heatsink you use because it comes already attached to the processor. If you have to attach it yourself, you should use a thermal transfer grease or sticky tape to fill any air gaps between the heatsink and the processor. This allows for maximum heat transfer and the best efficiency.

Obviously, active heatsinks offer greater cooling capacity than the passive types. Boxed processors from Intel and AMD are sold with the heatsink and fan included. And although OEM processors don't include a heatsink from the processor manufacturer, most vendors who sell them add an aftermarket heatsink and fan to the package; often, aftermarket heatsinks and fans provide significantly better cooling than those shipped with boxed processors. Thus, an OEM processor is a better candidate for overclocking.

Caution

All modern heatsinks require that a thermal interface material (usually tape, grease, or paste) be applied to the base of the heatsink before installation.

Another consideration for cooling is with the case. The fan in the power supply and the one on the CPU heatsink are not enough for a modern high-performance system. I recommend you get a case that includes at least one additional cooling fan. This is typically mounted in the rear of the chassis, directing additional air out the back. Some cases include an extra fan in the front or side cover as well.

If you are upgrading an existing system, several companies make fan assemblies that insert into a drive bay for additional cooling. They take the place of a 5 1/4" drive and take air in through the front bezel, directing it back into the case. Bay-mounted fans are an especially good idea if you are using a 10,000rpm or faster hard drive because they run extremely hot (most hard drives still spin at 7,200rpm). There are even fan assemblies mounted on cards that blow air out the rear of the case. Keep in mind that it is best to keep the interior of the PC below 100°F; anything over 110° dramatically reduces component life and leads to stability problems.

Cables

PC systems need many different cables to hook up everything. These can include power cables or adapters, floppy drive cables, parallel and Serial ATA drive cables, and many others. Frequently, the motherboard includes the cables for any of the internal ports, such as floppy or hard drives. Other external devices you purchase come with included cables, but in some cases, they aren't supplied. The Vendor List on the disc included with this book contains contact information for several cable and small parts suppliers that can get you the cables or other parts you need to complete your system.

If you build your system using all OEM (what the industry calls *white box*) components, be aware that these sometimes don't include the accessories, such as cables, software, and additional documentation, that you would get with a boxed-retail version of the same component.

Hardware

You might need screws, standoffs, mounting rails (if your case requires them), and other miscellaneous hardware to assemble your system. Most of these parts are included with the case or your other system components. This is especially true of any card or disk drive brackets or screws. When you purchase a component such as a hard drive, some vendors offer you the option of purchasing the bare drive or a kit containing the required cables and mounting hardware for the device. Most of the time bare drives don't include any additional hardware, but you might not need it anyway if the mounting hardware comes with your case. Even so, spending the few additional dollars for the complete drive kit is rarely a waste of money. Even if you're left with some extra bits and pieces after assembling your system, they will probably come in handy someday.

In situations in which you need other hardware not included with your system components, you can consult the Vendor List for suppliers of small parts and hardware necessary to get your system operational.

[< PREVIOUS](#)[NEXT >](#)

Hardware and Software Resources

When you are planning to build a system, it is important to consider how all your selected components will work together and how the software you run must support them. It is not enough to be sure that you have sufficient slots on the motherboard for all your expansion cards and enough bays in the case for all your drives. You must also consider the resources required for all the components.

For example, if you are planning to use FireWire devices, you need to know whether your new motherboard has FireWire ports built in or whether you will need to add a separate adapter card to achieve compatibility. With the many changes in processor speed and voltage, you also need to verify that the processor, memory, and motherboard combination you prefer will work correctly.

Essentially, you should completely configure the system before you begin ordering any parts. Planning a system to this level of detail can be a lot of work, which is one reason besides cost that the vast majority of PCs are prebuilt.

Tip

In most cases, you can download or view online the manuals for the motherboard, processor, and other major components before you purchase them. Check the component vendors' websites for these manuals and technical notes and read them carefully. You will need Adobe Acrobat Reader, available free from www.adobe.com, to view most online manuals.

Another consideration is the operating system and other software you need. Prebuilt systems nearly always arrive with the operating system installed, but when you build your own, you must be prepared with a copy of your selected operating system including a system disk so you can boot the system the first time. Because nearly any operating system in use today is distributed on CD-ROM, you must get your computer to recognize the CD-ROM drive before you can install an operating system. This is not usually an issue on modern systems, but if you intend to build a system based on legacy hardware and older versions of Windows (or DOS, for that matter), you should create a bootable CD. Note that the OEM versions of Windows 98 and later are bootable, but the retail upgrade versions of Windows 98 and Windows Me aren't, nor are any older versions of Windows. You can boot from both OEM and upgrade versions of Windows 2000 and Windows XP.

◀◀ See "[Making a Bootable CD/DVD for Emergencies](#)," p. [810](#).

The operating system you select for your new computer is another important decision. You must be certain that the OS supports all the hardware you've selected, which can occasionally be a difficult task. For example, you will need Windows 98 or later to properly support USB devices in your system, but in reality you should consider Windows XP or Windows 2000 Professional as your primary choices instead of Windows 9x or Windows Me.

About OEM Operating Systems

Because Microsoft doesn't allow OEM versions of its operating systems to be sold separately, if you intend to purchase one, be sure you order an OEM edition of whatever operating system you will be running at the same time you buy your hardware. The terms of the Microsoft dealer (or system builder) agreement allow dealers to sell the OS only with hardware. At one time you needed to buy a complete PC, a motherboard, or a hard disk to get an OEM version of the operating system, but you can now buy any hardware—even a device as inexpensive as a case fan or mouse—and qualify to buy the OEM version. No matter what, be sure you get the original OEM version on CD-ROM or DVD-ROM.

Tip

If you don't have the OEM version of your OS, or the system you are assembling does not support booting from CD (called El Torito support after the Phoenix-created standard), you must create a boot floppy with CD-ROM drivers. Windows 98 and later include a disk with a set of universal CD-ROM drivers that work for most systems; for Windows 95 and older operating systems, you must either borrow a Windows 98 or later startup disk or create your own bootable floppy with the correct drivers.

Drivers for specific hardware components, such as your motherboard chipset, might also be a problem. It is a good idea to gather all the latest driver revisions for your hardware, as well as BIOS flashes, firmware updates, and other software components, and have them available when you begin the assembly process.

[< PREVIOUS](#)[NEXT >](#)

System Assembly and Disassembly

Actually assembling the system is easy after you have lined up all the components. In fact, you will find the parts procurement phase the most lengthy and trying of the entire experience. Completing the system is basically a matter of screwing everything together, plugging in all the cables and connectors, and configuring everything to operate properly together.

In short order, you will find out whether your system operates as you had planned or whether some incompatibilities exist between some of the components. Be careful and pay attention to how you install all your components. It is rare that a newly assembled system operates perfectly the first time, even for experienced system builders. It is very easy to forget a jumper, switch, or cable connection that later causes problems in system operation. Most people's first reaction when problems occur is to blame defective hardware, but that is usually not the source. The problem can typically be traced to some missed step or error made in the assembly process.

Above all, the most crucial rule of assembling your own system is to save every piece of documentation and software that comes with every component in your system. This material can be indispensable in troubleshooting problems you encounter during the assembly process or later. You should also retain all the packing materials used to ship mail-order components to you until you are certain they will not have to be returned.

Assembly Preparation

The process of physically assembling a PC requires only a few basic tools: a 1/4" nut driver or Phillips-head screwdriver for the external screws that hold the cover in place and a 3/16" nut driver or Phillips-head screwdriver for all the other screws. Needle-nose pliers can also help in removing motherboard standoffs, jumpers, and stubborn cable connectors. Because of marketplace standardization, only a couple types and sizes of screws (with a few exceptions) are used to hold a system together. Also, the physical arrangement of the major components is similar even among different manufacturers. [Figure 20.2](#) shows the components that go into a typical system, and [Figure 20.3](#) shows the system with those components assembled. Note that the components shown here are for a standard PC. Your final component list might vary.

Figure 20.2. Components used in building a typical PC. The case and drive screws and the standoffs are not shown but are usually provided with the case and drives.

[\[View full size image\]](#)

Figure 20.3. The completed system using all components shown in [Figure 20.2](#).

You'll find more information on tools used to work on PCs in [Chapter 22](#), "PC Diagnostics, Testing, and Maintenance."

Other tools you'll need are software related. You'll need the master operating system disc, and if your particular OS version isn't bootable or your system is older and doesn't support booting from CD, you'll also need an operating system startup floppy disk with CD-ROM drivers installed. This way, your system will recognize the CD-ROM drive and enable you to install the operating system from it.

The Windows 98 and later versions' startup floppies include generic ATAPI and SCSI CD-ROM drivers on them, enabling virtually all CD-ROMs to be recognized after booting from them. If you are installing Windows 95 or some other operating system that does not include a startup disk with CD-ROM drivers already installed, you can either use a Win98 or later startup disk or take your existing startup disk and install the CD-ROM drivers that came with your drive. That procedure is covered later in this chapter.

The following sections cover the assembly and disassembly procedure:

- Case or cover assembly
- Power supply
- Adapter boards
- Motherboard
- Disk drives

Later, you learn how to install and remove these components for several types of systems. With regard to assembly and disassembly, it is best to consider each system by the type of case it uses. All systems that have AT-type cases, for example, are assembled and disassembled in much the same manner. Tower cases are basically AT-type cases turned sideways, so the same basic instructions apply. Most Slimline and XT-style cases are similar; these systems are assembled and disassembled in much the same way.

The following section lists assembly and disassembly instructions for several case types.

ESD Protection

One issue you must be aware of is electrostatic discharge (ESD) protection. Another is recording the configuration of the system with regard to the physical aspects of the system (such as jumper or switch settings and cable orientations) and the logical configuration of the system (especially in terms of elements such as CMOS settings).

When you are working on the internal components of a computer, you must take the necessary precautions to prevent accidental static discharges to the components. At any time, your body can hold a large static voltage charge that can easily damage components of your system. Before I ever put my hands into an open system, I first touch a grounded portion of the chassis, such as the power supply case. This action serves to equalize the electrical charges the device and my body might be carrying. Be sure the power supply is unplugged during all phases of the assembly process. Some will claim that you should leave the system plugged in to provide an earth ground through the power cord and outlet, but that is unnecessary. If you leave the system plugged in, you open yourself up to other problems, such as accidentally turning it on or leaving it on when installing a board or device, which can damage the motherboard or other devices.

Caution

Also note that power supplies used in many systems today deliver a +5V current to the motherboard continuously that is, whenever they are plugged in. Bottom line: Be sure any system you are working on is completely unplugged from the wall outlet.

High-end workbenches at repair facilities have the entire bench grounded, so it's not as big of a problem; however, you need something to be a good ground source to prevent a current from building up in you.

A more sophisticated way to equalize the charges between you and any of the system components is to use an ESD protection kit. These kits consist of a wrist strap and mat, with ground wires for attachment to the system chassis. When you are going to work on a system, you place the mat next to or partially below the system unit. Next, you clip the ground wire to both the mat and the system's chassis, tying the grounds together. You then put on the wrist strap and attach that wire to a ground. Because the mat and system chassis are already wired together, you can attach the wrist-strap wire to the system chassis or to the mat. If you are using a wrist strap without a mat, clip the wrist-strap wire to the system chassis. When clipping these wires to the chassis, be sure to use an area that is free of paint so a good ground contact can be achieved. This setup ensures that any electrical charges are carried equally by you and any of the components in the system, preventing the sudden flow of static electricity that can damage the circuits.

As you install or remove disk drives; adapter cards; and especially delicate items such as the entire motherboard, memory modules, or processors, you should place these components on the static mat. Sometimes people put the system unit on top of the mat, but the unit should be alongside the mat so you have room to lay out all the components as you work with them. If you are going to remove the motherboard from a system, be sure you leave enough room for it on the mat.

If you do not have such a mat, place the removed circuits and devices on a clean desk or table. Always pick up a loose adapter card by the metal bracket used to secure the card to the system. This bracket is tied into the ground circuitry of the card, so by touching the bracket first, you prevent a discharge from damaging the components of the card. If the circuit board has no metal bracket (a motherboard, for example), handle the board carefully by the edges, and try not to touch any of the connectors or components. If you don't have proper ESD equipment such as a wrist strap or mat, be sure to periodically touch the chassis while working inside the system to equalize any charge you might have built up.

Caution

Some people recommend placing loose circuit boards and chips on sheets of aluminum foil. I absolutely *do not recommend* this procedure because it can actually result in an explosion! Many motherboards, adapter cards, and other circuit boards today have built-in lithium or NiCad batteries. These batteries react violently when they are shorted out, which is exactly what you would be doing by placing such a board on a piece of aluminum foil. The batteries will quickly overheat and possibly explode like a large firecracker (with dangerous shrapnel). Because you will not always be able to tell whether a board has a battery built in to it somewhere, the safest practice is to never place any board on any conductive metal surface. Instead, use cardboard or newspapers if you don't have an antistatic work mat or sufficient antistatic bags.

Recording Physical Configuration

While you are assembling a system, you should record all the physical settings and configurations of each component, including jumper and switch settings, cable orientations and placement, ground wire locations, and even adapter board placement. Keep a notebook handy for recording these items, and write down all the settings. See [Chapter 4](#) for more information on motherboard connector, jumper, and other component locations. [Figure 20.4](#) shows a typical motherboard jumper.

Figure 20.4. Motherboard jumpers often are silk-screened on the motherboard, as shown here; the jumper position shown here is used to configure the motherboard's PCI and USB interface.

It is especially important to record all the jumper and switch settings on the motherboard, as well as those on any card you install in the system (cards seldom use jumpers or switches today, but some motherboards still do). If you accidentally disturb these jumpers or switches, you will know how they were originally set. This knowledge is very important if you do not have all the documentation for the system handy. Even if you do, undocumented jumpers and switches often do not appear in the manuals but must be set a certain way for the item to function. Also, record all cable orientations. Most name-brand systems use cables and connectors that are keyed so that they can't be plugged in backward, but some generic PCs do not have this added feature. You should mark or record what each cable was plugged in to and its proper orientation. Ribbon cables usually have an odd-colored (red, green, blue, or black) wire at one end that indicates pin 1. There might also be a mark on the connector, such as a triangle or even the number 1. The devices the cables are plugged in to are also marked in some way to indicate the orientation of pin 1. Often, a dot appears next to the pin 1 side of the connector, or a 1 or other mark might appear.

Although cable orientation and placement seem to be very simple, we rarely get through the entire course of my PC troubleshooting seminars without at least one group of people having cable-connection problems. Fortunately, in most cases (except power cables), plugging any of the ribbon cables inside the system backward doesn't cause any permanent damage.

Power and battery connections on pre-ATX systems are exceptions; plugging them in backward in most cases causes damage. In fact, plugging the motherboard power connectors in backward or in the wrong plug location on these older systems puts 12V where only 5V should be a situation that can cause components of the board to violently explode. I know of several people who have facial scars caused by shrapnel from components that exploded because of improper power supply connections! As a precaution, I always turn my face away from the system when I power it on for the first time. If you are using an ATX board and power supply, there is little chance of this happening because of the superior type of power

connector used *unless* you mix a September 1998 or newer Dell power supply or motherboard with a standard motherboard or power supply.

Plugging in the CMOS battery backward can damage the CMOS chip, which usually is soldered into the motherboard; in such a case, the motherboard must be replaced.

Finally, you should record miscellaneous items such as the placement of any ground wires, adapter cards, and anything else that you might have difficulty remembering later. Some configurations and setups might be particular about the slots in which the adapter cards are located, so you should put everything back exactly the way it was originally.

Motherboard Installation

When you are installing your system's motherboard, unpack the motherboard and check to ensure you have everything that should be included. If you purchase a new board, you typically get at least the motherboard, some I/O cables, and a manual. If you order the motherboard with a processor or memory, it is usually installed on the board for you but might also be included separately. Some board kits include an antistatic wrist strap to help prevent damage due to static electricity when installing the board.

Installing the CPU and Heatsink

Before your new motherboard is installed, you should install the processor and memory. This usually is much easier to do before the board is installed in the chassis. Some motherboards have jumpers that control both the CPU speed and the voltage supplied to it. If these are set incorrectly, the system might not operate at all, might operate erratically, or might possibly even damage the CPU. If you have any questions about the proper settings, contact the vendor who sold you the board before making any jumper changes.

◀◀ See "[CPU Operating Voltages](#)," p. [101](#).

All processors today run hot enough to require some form of heatsink to dissipate heat from the processor. To install the processor and heatsink, use the following procedure:

1. Prep the motherboard. Take the new motherboard out of the antistatic bag it was supplied in and set it on the bag or the antistatic mat, if you have one.
2. Install the processor. First, find pin 1 on the processor; it usually is denoted by a corner of the chip that is marked by a dot or bevel. Next, find the corresponding pin 1 of the ZIF socket for the CPU on the motherboard; it also is usually marked on the board or with a bevel in one corner of the socket. Be sure the pins on the processor are straight and not bent; if they are bent, the chip won't insert properly into the socket. If necessary, use small needle-nose pliers or a hemostat to carefully straighten any pins. Don't bend them too much they might break off, ruining the chip. Insert the CPU into the ZIF socket by lifting the release lever until it is vertical. Then, align the pins on the processor with the holes in the socket and drop it down into place. If the processor does not seem to want to drop in all the way, remove it to check for proper alignment and any possibly bent pins. When the processor is fully seated in the socket, push the locking lever on the socket down until it latches to secure the processor (see [Figure 20.5](#)).

Figure 20.5. The lever on a ZIF socket locks the processor into the socket when lowered. Note the triangle on the corner of the processor, denoting pin 1.

[\[View full size image\]](#)

Note

If you require instructions for installing slot-based processors, refer to the section "[Installing the CPU and Heatsink](#)," in [Chapter 22](#) of the 16th Edition of this book, included on the DVD.

3. Attach the heatsink. Most heatsinks clip to the socket with one or more retainer clips (see [Figure 20.6](#)). Be careful when attaching the clip to the socket; you don't want it to scrape against the motherboard, which can damage circuit traces or components. You also need to keep the heatsink steady on the chip while attaching the clips, so do not move, tilt, or slide the heatsink while you attach it. Most heatsinks have a preapplied thermal pad; otherwise, you will need to put a dab of heatsink thermal transfer compound (normally a white- or silver-colored grease) on the CPU before installing the heatsink. This prevents any air gaps and enables the heatsink to work more efficiently. If the CPU has an active heatsink (with a fan), plug the fan power connector into one of the fan connectors supplied on the motherboard (see [Figure 20.7](#)). Optionally, some heatsinks use a disk drive power connector for fan power.

Figure 20.6. Attaching the heatsink to a socketed processor. The retaining clip is spring-loaded, so it must be positioned with a screwdriver or similar tool that can push the clip down and swing it into place.

[\[View full size image\]](#)

Figure 20.7. Attaching the heatsink fan power connector to the motherboard.

[\[View full size image\]](#)

4. Configure the motherboard jumpers (if necessary). Refer to the motherboard manufacturer's manual to set the jumpers, if any, to match the CPU you are going to install. Most of the time the motherboard BIOS handles this process, but if manual configuration is necessary, look for the diagram of the motherboard in the manual to find the jumper location, and look for the tables for the correct settings for your CPU. If the CPU supplied was already installed on the motherboard, the jumpers should already be correctly set for you, but it is still a good idea to check them.

Installing Memory Modules

To function, the motherboard must have memory installed on it. Modern motherboards use either DDR or DDR2 DIMMs. Depending on the module type, it will have a specific method of sliding into and clipping to the sockets. Usually, you install modules in the lowest-numbered sockets or banks first. Note that dual-channel boards perform best if modules are installed in matched pairs. Older legacy systems, particularly those based on RDRAM, often require memory to be installed in pairs. Consult the motherboard documentation for more information on which sockets to use first and in what order and how to install the specific modules the board uses.

◀◀ See "[Memory Banks](#)," p. [512](#).

Because memory modules are keyed to the sockets by a notch on the side or bottom, they can go in only one way. [Figure 20.8](#) shows how to install a DIMM or RIMM; more detailed instructions for installing memory modules can be found in [Chapter 6](#).

Figure 20.8. Installing the memory modules. Make sure the locking clips are open on both sides of the module before the module is inserted into the memory socket (left). Press down on the module until the module locking clips swing up into the locked position (right).

[\[View full size image\]](#)

Caution

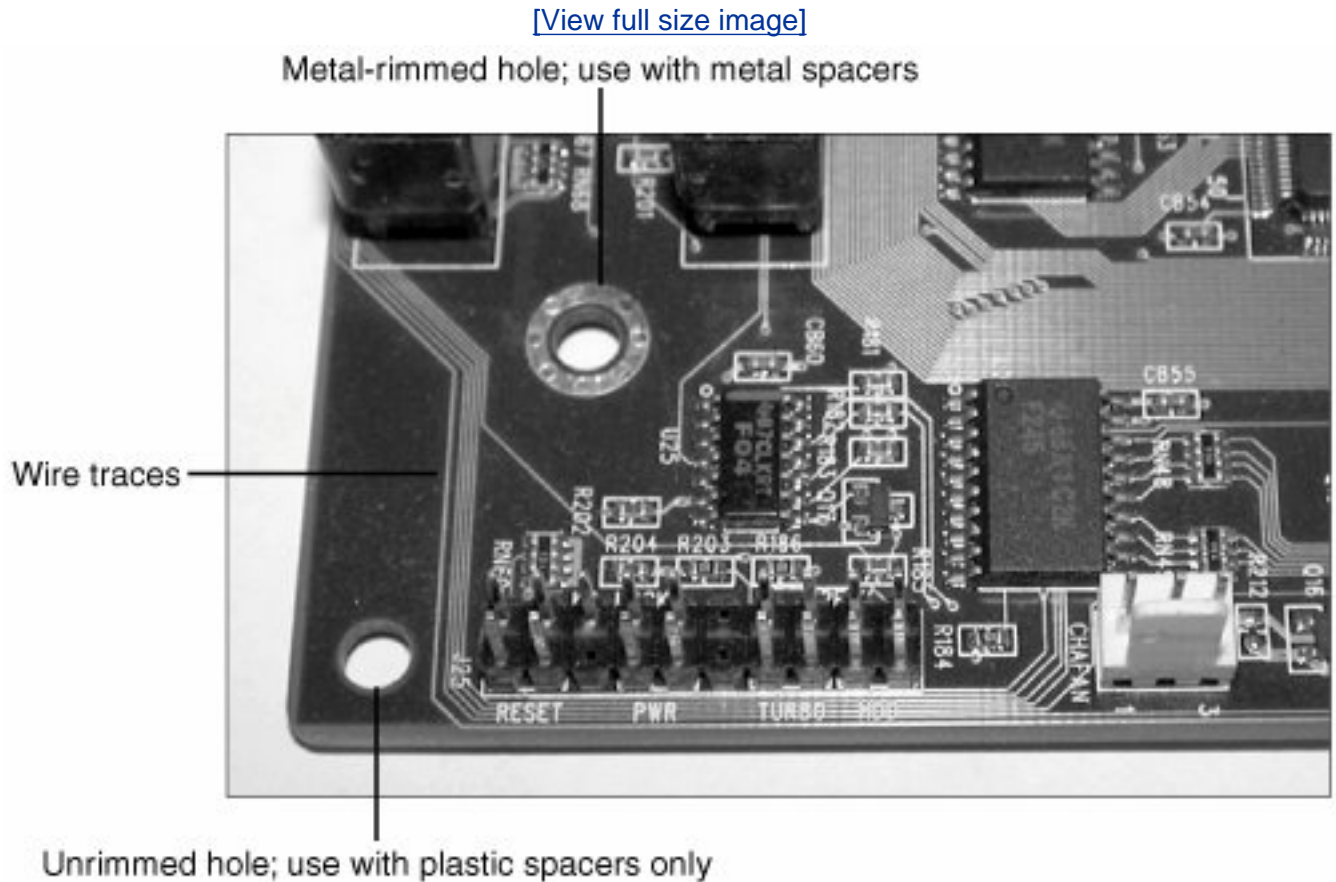

Be careful not to damage the connector. If you damage the motherboard memory connector, you could be facing an expensive repair. Never force the module; it should come out easily. If it doesn't, you are doing something wrong.

Mounting the New Motherboard in the Case

The motherboard attaches to the case with one or more screws and often several plastic standoffs. If you are using a new case, you might have to attach one or more metal spacers or plastic standoffs in the proper holes before you can install the motherboard. Use the following procedure to install the new motherboard in the case:

1. Find the holes in the new motherboard for the metal spacers and plastic standoffs. You should use metal spacers wherever there is a ring of solder around the hole. Use plastic standoffs where there is no ring of solder (see [Figure 20.9](#)).

Figure 20.9. The corner of a typical motherboard. Be sure not to damage the wire traces when attaching the motherboard to the case.

2. Screw any metal spacers into the new case in the proper positions to align with the screw holes in the motherboard (see [Figure 20.10](#)).

Figure 20.10. Make sure the standoffs align with the holes in the motherboard. Note that this chassis has a variety of mounting holes so you can adjust the position of the standoffs to match various motherboard designs.

3. Most motherboards today attach directly to the chassis or to a removable motherboard tray with screws that thread into brass standoffs attached to the chassis or tray. [Figure 20.11](#) shows three types of standoffs, including two brass types and one plastic. One screws directly to the chassis or tray, whereas the others attach to the motherboard and then slide into notches in the case or tray.

Figure 20.11. Various types of motherboard standoffs, used to support the board when installed in the chassis or motherboard tray.

If the board uses the type of standoff that fits into slots in the chassis or tray, rather than screwing directly in, insert the standoffs directly into the new motherboard from underneath until they snap into place (see [Figure 20.12](#)). Or attach them to the board with a screw if necessary. [Figure 20.13](#) shows a typical ATX-style motherboard with arrows indicating the typical location of the screw holes for mounting the motherboard to the case (see your motherboard manual for the exact location of these screw holes).

Figure 20.12. Insert standoffs into their mounting slots by sliding a Baby-AT motherboard into place after attaching standoffs.

Figure 20.13. Mounting screw holes in a typical ATX motherboard. The highlighted circles mark the screw holes for mounting the motherboard to the case.

After you have inserted the standoffs and lined them up with the screw holes on the motherboard, carefully attach the screws to secure the motherboard to the motherboard tray or case, depending on your chassis design. [Figure 20.14](#) shows a motherboard attached to a tray. Note the use of the thumb and forefinger to stabilize the screwdriver tip. This prevents accidental slippage of the screwdriver tip off of the screw, which is one of the biggest causes of new board failures.

Figure 20.14. Attaching a motherboard to the motherboard tray.
Motherboard courtesy of Intel Corporation.

4. Install the I/O shield (if used) into the chassis by snapping it into place (see [Figure 20.15](#)).

Figure 20.15. The I/O shield after being snapped into place in the chassis.

5. Install the new motherboard into the case or motherboard tray. Either screw it directly to the standoffs or slide the standoffs already attached to the board by sliding the entire board into position. Be sure you align the I/O shield with the case or the ports on the back of the board with the I/O shield already in the case. Often, you will have to set the board into the case and slide it sideways to engage the standoffs into the slots in the case. When the board is in the proper position, the screw holes in the board should be aligned with all the metal spacers or screw holes in the case. [Figure 20.16](#) shows a motherboard attached to a motherboard tray being installed in the chassis.

Figure 20.16. Installing a motherboard and tray into the chassis. Case courtesy of PC Power & Cooling, Inc. Motherboard courtesy of Intel Corporation.

Some cases and boards, particularly ATX types, don't use any plastic spacers. Instead they use up to seven screws into metal standoffs that are installed in the case (refer to [Figure 20.10](#)). These are somewhat easier to install because the board drops into place and doesn't require that it be moved to the side to engage any standoffs.

6. Take the screws and any plastic washers that were supplied with the new motherboard and screw the board into the case (see [Figure 20.17](#)).

Figure 20.17. Installing the screws that hold the motherboard to the chassis.

Connecting the Power Supply

The power supply is very easy to install, and it usually attaches to the chassis with four screws. [Figures 20.18](#) and [20.19](#) show installing the power supply into the chassis and tightening the screws.

Figure 20.18. Installing the power supply into the chassis.

Figure 20.19. Installing the screws to retain the power supply.

ATX-style motherboards have a single power connector that can go on only one way and an optional secondary connector that is also keyed (see [Figure 20.20](#)). ATX supplies can also be used in a standard BTX

case (but not Pico/Micro). Baby-AT and other old-style board designs such as LPX usually have two separate six-wire power connectors from the power supply to the board, which might not be keyed and therefore might be interchangeable. If you still work with Baby-AT or LPX systems, refer to [Chapter 19](#) for important information on proper installation of Baby-AT power supplies. Even though you might be able to insert them several ways, only one way is correct! These power leads usually are labeled P8 and P9 in most systems. The order in which you connect them to the board is crucial; if you install them backward, you can damage the motherboard when you power it up. Many systems use a CPU cooling fan, which should also be connected. To attach the power connectors from the power supply to the motherboard, do the following:

1. If the system uses a single ATX-style power connector, plug it in; it can go on only one way. Some ATX systems also use a 6-pin auxiliary connector or a 4-pin ATX12V connector. These are also keyed and plug in only one way. If the system is not ATX and two separate six-wire connectors are used instead, the two black ground wires on the ends of the connectors must meet in the middle. Align the power connectors such that the black ground wires are adjacent to each other, and plug in the connectors. Consult the documentation with your board to ensure that the power supply connection is correct. Incorrectly connecting the power connectors can destroy the motherboard.
2. Plug in the power lead for the CPU fan if one is used. The fan will either connect to the power supply via a disk drive power connector or connect directly to a fan power connector on the motherboard.

Figure 20.20. Attaching an ATX motherboard power connector.

Note

Refer to [Chapter 19](#) for detailed coverage of the various types of power supply connectors, including new connectors used with the Intel Pentium 4.

Connecting I/O and Other Cables to the Motherboard

Several connections must be made between a motherboard and the case. These include LEDs for the hard

disk and power, an internal speaker connection, a reset button, and a power button. Most modern motherboards also have several built-in I/O ports that have to be connected. This includes dual IDE host adapters, a floppy controller, and front-mounted USB or IEEE 1394 ports. Some boards also include additional items such as built-in video, sound, or SCSI adapters.

If the board is an ATX type, the connectors for all the external I/O ports are already built in to the rear of the board. If you are using a legacy Baby ATtype board, you might have to install cables and brackets to run the serial, parallel, and other external I/O ports to the rear of the case.

If your motherboard has onboard I/O (nearly all PCs today use onboard I/O), use the following procedure to connect the cables:

1. Connect the floppy cable between the floppy drives and the 34-pin floppy controller connector on the motherboard.
2. Connect the IDE cables between the hard disk, IDE CD-ROM, and 40-pin primary and secondary IDE connectors on the motherboard (see [Figure 20.21](#)). Typically, you will use the primary IDE channel connector for hard disks only and the secondary IDE channel connector to attach an IDE CD-ROM or other device, such as a tape drive. If you have a Serial ATA hard disk and a Serial ATA host adapter on the motherboard, connect the Serial ATA cable from the hard disk to the host adapter connection on the motherboard.

Figure 20.21. Floppy, ATA, and Serial ATA hard drive connectors.

3. On non-ATX boards, a 25-pin female cable port bracket is used for the parallel port. Usually two serial ports exist: a 9-pin and either another 9-pin or a 25-pin male connector port. Align pin 1 on the serial and parallel port cables with pin 1 on the motherboard connector, and then plug them in.
4. If the ports don't have card slottype brackets or if you need all your expansion slots, the back of the case might have port knockouts you can use instead. Find ones that fit the ports, and push them out, removing the metal piece covering the hole. Unscrew the hex nuts on each side of the port connector, and position the connector in the hole. Install the hex nuts back in through the case to hold the port connector in place.
5. Most newer motherboards also include a built-in mouse port. If the connector for this port is not built in to the back of the motherboard (typically next to the keyboard connector), you probably have a card brackettype connector to install. In that case, plug the cable into the motherboard mouse connector, and then attach the external mouse connector bracket to the case.
6. Attach the front-panel switch, LED, internal speaker wires, and front-mounted ports such as USB and IEEE 1394 from the case front panel to the motherboard. If they are not marked on the board, check where each one is on the diagram in the motherboard manual. [Figure 20.22](#) shows the front-panel connectors.

Figure 20.22. The motherboard front-panel connectors (speaker, power switch, LEDs, and so on) must be connected to the appropriate pins on the motherboard (bottom center).

Installing the Drives

At this point you should install your hard drive, floppy drive, and optical drive. This is covered in detail in [Chapter 12](#), "Physical Drive Installation and Configuration."

The basic process for mounting optical drives, hard drives, and floppy drives is as follows:

1. Remove the drive bay plates (if needed). Simply bend or knock the plate out of the way.

2. To install a CD drive, simply slide the drive into the chassis. Note that it is easier to connect the IDE cable to the rear of the drive and make jumper selections before mounting the drive. Refer to [Chapters 7](#) and [12](#) for more about IDE jumpers and drive installation. Note that some cases come with rails that must be added to 5 1/4" wide drives, such as an optical drive. In such cases, use the screws from step 3 for the drive rails.
3. After the drive is in the bay, line up the drive-mounting screw holes on the drive with the holes in the case chassis. Secure the drive with four screws, using the ones that came with your case or the drive you are installing (see [Figure 20.23](#)). If the drive uses rails, the rails hold the drive in place.

Figure 20.23. Secure the drive to the chassis using four screws.

4. Connect the other end of the IDE cable to your motherboard's IDE connector or to the back of another IDE device if you are chaining drives.
5. If your system has a removable drive cage, for floppy and hard disk drives, you should remove the cage.
6. To install floppy and hard drives, slide your drives into the drive cage and secure them with the screws that came with your case or with the drive you are installing (see [Figure 20.24](#)). As with an optical drive, it's easier to connect the floppy and IDE cables to the rear of the drives and make any jumper selections prior to placing the drives or the drive cage into the chassis.

Figure 20.24. Use four screws to secure each drive to the drive bay. If your computer uses a removable drive cage, mount the drives to the drive cage in the same way.

Note

If your chassis does not include a removable drive cage, as shown in [Figure 20.25](#), you'll simply have to mount the drives in the chassis. This is a little more difficult because there's not much working room inside a PC.

Figure 20.25. The drive cage inserts into the chassis and is usually held in place by two or four screws. *Chassis courtesy of PC Power & Cooling, Inc. Hard drive supplied by Micro X-Press.*

7. If your system has a removable drive cage, slide the drive cage back into the PC and secure it to the chassis using the screws provided with your case (see [Figure 20.25](#)).
8. Connect the drive cables to the appropriate locations on your motherboard. Refer to [Chapters 7](#) and [12](#) for more about jumper settings and cable connections for hard drives and floppy drives.

Installing the New Video Card and Driver Software

Follow these steps to install a new video card into a system:

1. If necessary, remove the screw and slot cover behind the expansion slot you want to use for the new video card.

2. Slide the video card straight down into the slot where it will be installed (typically an AGP or a PCI Express slot).
3. Push the card down into the slot, using a front-to-back rocking motion if necessary to get the edge connector to slide into the slot.
4. Use either the screw you removed during removal of the old card or the screw used in step 1 to fasten the card into place.
5. Attach the video cable from the monitor to the proper connector at the rear of the monitor. If the new card uses a DVI-I connector and the monitor uses the standard 15-pin VGA connector, use a DVI-to-VGA adapter (usually provided with the video card or available separately from stores that stock computer parts). If you're building a dual-display system, be sure to plug in your primary and secondary displays to the appropriate connectors.

Note

If you are replacing an existing video card (or switching from onboard video to an add-in video card), you should remove the existing installed video driver before powering down to install the new card. This helps prevent the system from improperly identifying the new video card and makes for a smoother upgrade. To do this, open the Windows Device Manager, select the existing display adapter, and select Remove or Uninstall. Do not reboot the system if asked; instead, you can power down and remove the existing video card.

After the entire system is assembled, when the system boots up, Windows should detect the new video card and automatically begin the driver installation process. At that point, follow the manufacturer's instructions for installing the latest video drivers for the new video card. After the video card drivers are installed, you can use the Windows Display properties to fine-tune its settings for resolution, color depth, or refresh rate if desired.

Installing Additional Expansion Cards

Many systems use additional expansion cards for wireless Ethernet, Internet connection (modem), sound, and SCSI adapters. These cards are plugged in to the bus slots present on the motherboard. To install these cards, follow these steps:

1. Insert each card by holding it carefully by the edges, being sure not to touch the chips and circuitry. Put the bottom-edge finger connector into the appropriate open slot (usually PCI or PCI Express). Firmly press down on the top of the card, exerting even pressure, until it snaps into place (see [Figure 20.26](#)).

Figure 20.26. This photo shows a video adapter being inserted into the slot. *Motherboard courtesy of Intel Corporation.*

2. Secure each card bracket with a screw (see [Figure 20.27](#)).

Figure 20.27. Installing the screw to retain the card. *Motherboard courtesy of Intel Corporation.*

3. Attach any internal cables you might have removed earlier from the cards.

Replacing the Cover and Connecting External Cables

Now the system should be nearly assembled. All that remains is installing the cover assembly and connecting any external devices that are cabled to the system. I usually don't like to install the case cover screws until I have tested the system and am sure everything is working properly. Often, I find that a cable has been connected improperly or some jumper setting is not correct, requiring that I remove the cover to repair the problem. Use the following procedure to complete the assembly:

1. Slide the cover onto the case.
2. Before powering up the system, connect any external cables. Most of the connectors are D-shaped and go in only one way.
3. Plug the 15-pin monitor cable into the video card female connector.
4. Attach the phone cord to the modem, if any.
5. Plug the round keyboard cable into the keyboard connector, and plug the mouse into the mouse port or serial port (if you are using a serial mouse). If you're using a USB keyboard or mouse, plug it into any free USB port.
6. If you have any other external cabling, such as joystick or audio jacks to a sound card, attach them now.

Running the Motherboard BIOS Setup Program (CMOS Setup)

Now that everything is connected, you can power up the system and run the BIOS Setup program. This enables you to configure the motherboard to access the installed devices and set the system date and time. The system also tests itself to determine whether any problems exist. Do the following:

1. Power on the monitor first and then the system unit. Observe the operation via the screen and listen for any beeps from the system speaker.
2. The system should automatically go through a power on self test (POST) consisting of video BIOS checking, a RAM test, and usually an installed component report. If a fatal error occurs during the POST, you might not see anything onscreen and the system might beep several times, indicating a specific problem. Check the motherboard or BIOS documentation to determine what the beep codes mean.
3. If there are no fatal errors, you should see the POST display onscreen. Depending on the type of motherboard BIOS, such as Phoenix, AMI, Award, or others, you have to press a key or series of keys to interrupt the normal boot sequence and get to the Setup program screens that enable you to enter important system information. Normally, the system indicates via the onscreen display which key to press to activate the BIOS Setup program during the POST, but if not, check the motherboard manual for the key(s) to press to enter the BIOS Setup. Common keys used to enter BIOS Setup are F1, F2, F10, Esc, Ins, and Del.
4. After the Setup program is running, use the Setup program menus to enter the current date and time, your hard drive settings, floppy drive types, video cards, keyboard settings, and so on.

5. Entering the hard drive information is most critical when building a new system. Most modern BIOSs feature an autodetect or auto-type setting for the drive; I recommend you choose that if it is available. This causes the BIOS to read the parameters directly from the drive, which eliminates a chance for errors especially if the builder is less experienced. These parameters include CHS (cylinder head sector) specifications and transfer speed and translation settings such as LBA. Most systems also let you set a *user-definable type*, which means that the cylinder, head, and sector counts for this type were entered manually and are not constant. If you set a user-definable type (not normally recommended unless you don't have "auto" as a choice), it is especially important to write down the exact settings you use if you don't use Auto because this information might be very difficult to figure out if it is ever lost.

Modern ATA drives also have additional configuration items you should record if you set them manually. These include the translation mode and transfer speed setting. With drives larger than 528MB, you should record the translation mode, which is expressed differently in different BIOS versions. Look for settings such as CHS, ECHS (Extended CHS), Large (which equals ECHS), or LBA (logical block addressing). Typically, you set LBA or Large for any drive over 528MB. Whatever you set, it should be recorded because changing this setting after the drive has been formatted can cause problems.

6. After you have checked all the settings in the BIOS Setup, follow the instructions onscreen or in the motherboard manual to save the settings and exit the Setup menu.

◀◀ See "[Running or Accessing the CMOS Setup Program](#)," p. [443](#).

Troubleshooting New Installations

At this point, the system should reset and attempt to boot normally from either a floppy disk or a hard disk. With the operating system startup disk in the floppy drive or the bootable operating system CD in the CD-ROM drive, the system should boot and either reach an installation menu or a command prompt. If any problems exist, here are some basic items to check:

- *If the system won't power up at all, check the power cord.* If the cord is plugged in to a power strip, make sure the strip is switched on. Usually, a power switch can be found on the front of the case, but some power supplies have a switch on the back as well.
- *Check to see whether the power switch is connected properly inside the case.* There is a connection from the switch to the motherboard; check both ends to ensure that they are connected properly.
- *Check the main power connector from the supply to the board.* Make sure the connectors are seated fully, and if the board is a Baby-AT type, ensure that they are plugged in with the correct orientation and sequence.
- *If the system appears to be running but you don't see anything on the display, check the monitor to ensure that it is plugged in, turned on, and properly and securely connected to the video card.*
- *Check the video card to ensure it is fully seated in the motherboard slot.* Remove and reseat the video card, and possibly try a different slot if it is a PCI card.
- *If the system beeps more than once, the BIOS is reporting a fatal error of some type.* See the BIOS Error code listings in [Chapter 5](#) and on the disc accompanying this book for more information on what these codes mean because they depend on the type and version of BIOS you have. Also, consult your motherboard documentation look in the BIOS section for a table of beep codes.
- *If the LED on your floppy drive, hard drive, or CD/DVD-ROM drive stays on continuously, the data cable is probably installed backward or is off by some pins.* Check that the stripe on the cable is properly oriented toward pin 1 on both the drive and board connector ends. Also, check the drive jumpers for proper master/slave relationships.

When you are sure the system is up and running successfully, power it off and screw the chassis cover securely to the case. Now your new system should be ready for the operating system installation.

Installing the Operating System

If you are starting with a new drive, you must install the operating system. If you are using a non-Windows operating system, follow the documentation for the installation procedures.

On a newer system in which you are installing an OEM version of Windows 98 or later (which comes on a bootable CD), there isn't really anything you need to do, other than simply booting from the CD (you might have to enable the CD-ROM as a boot device in your BIOS Setup) and following the prompts to install the OS. Windows 98 or later versions automatically recognize that the drive needs to be partitioned and the partitions formatted before the installation can proceed. Additionally, Windows 98 or later versions execute these functions for you, with prompts guiding you along the way. This is the method I recommend for most people because it is relatively simple and straightforward.

If you want to do the partitioning and formatting manually (prior to installing the OS), follow the guidelines in the next few sections.

Partitioning the Drive with DOS and Windows 9x and Me

From the **A: >** prompt, with the startup disk inserted in the floppy drive, type the following command:

FDISK

This command is used to partition your drive. Follow the menus to create either a single partition for the entire drive or multiple partitions. Usually, the first partition must also be made active, which means it will be bootable. I recommend you answer Yes to the prompt **Do you wish to enable large disk support (Y/N)?**. This enables the partition to be created using the FAT32 or NTFS file system. Then, you can continue accepting default entries for all the prompts to partition the drive as a single bootable partition that covers the entire drive.

Next, exit FDISK; this restarts the system.

Note

Using FDISK was covered extensively in [Chapter 12](#).

Formatting the Drive with DOS and Windows 9x and Me

After rebooting on the startup floppy, you need to format each partition you've created. The first partition is formatted using the **FORMAT** command as follows:

FORMAT C:

All other partitions are formatted in the same manner: Merely run the command, changing the drive letter for each partition that needs to be formatted.

After the **FORMAT** command completes on all the drives, you should reboot again from the startup floppy. Now you are ready to install Windows.

Note

Drive formatting was covered extensively in [Chapter 9](#), "Hard Disk Storage." Refer to [Chapter 12](#) for more details on installing and setting up a hard drive.

Preparing the Hard Drive with Windows 2000/XP

If you are using Windows 2000 or Windows XP, the operating system prepares the drive for you during installation if you install the operating system to an empty drive. If unpartitioned space is available on an existing boot drive, you can direct Windows Setup to use that space and install as a "dual-boot" configuration. This configuration enables you to select your old version or new version of Windows each time you start your computer. You can also replace your existing version of Windows.

If Windows Setup prepares your drive, you can select the file system (FAT32 or NTFS) during the process. After Windows has partitioned and formatted the drive, it completes the installation process.

Loading the CD-ROM Driver

If your system supports booting from the CD and you are installing a version of Windows that comes on a bootable CD, you can disregard this section because the CD-ROM drivers automatically are loaded as you boot from the CD. You can then either proceed with the installation from the CD or copy the OS files from the CD to the hard drive and install from the hard drive instead.

If you must first boot from a floppy (because your system can't boot from a CD or your version of Windows isn't bootable), you must make sure your startup floppy disk is properly configured to support the CD/DVD drive in your system. This requires that real-mode (DOS-based) drivers be installed on the disk that is compatible with your drive. The easiest solution is to use a Windows 98 or later startup floppy disk because it is already prepared with the proper drivers for 99% of all systems on the market. Even if you are installing Windows 95, you can still use the Windows 98 or later startup disk to start the process.

If you are using a Windows 95 startup disk and you don't have the CD-ROM drivers on it, you should look for a CD-ROM driver disk that usually comes with your drive. It should have a driver installation batch file on it that, if run, will copy the drivers to your startup disk and create the appropriate **CONFIG.SYS** and **AUTOEXEC.BAT** files to enable CD-ROM support. If the driver is called **CDROM.SYS**, that file along with the following line (or something similar) should be added to the **CONFIG.SYS** file on your Windows 95 startup disk:

```
device=CDROM.SYS /D: oemcd001
```

This causes the CDROM.SYS driver to be loaded and assigns it an in-memory driver designation of **oemcd001**. Any designation can be used here, but it should be eight characters or fewer and must match a similar designation in the next step.

Next, you must load the Microsoft CD-ROM extensions driver in your **AUTOEXEC.BAT** file. This driver is called

MSCDEX.EXE and is already included on the Windows 95 startup disk. If you used the designation I listed in the previous step, add the following line to the **AUTOEXEC.BAT** file on the Windows 95 startup disk:

```
LH MSCDEX.EXE /D: oemcd001
```

This loads the **MSCDEX.EXE** driver (in upper memory via the LH or LoadHigh command if possible) and looks to attach to the CD-ROM driver loaded earlier via the driver designation **oemcd001** in this case.

After these statements are added to the **CONFIG.SYS** and **AUTOEXEC.BAT** files, you should reboot on the startup floppy. Now you also should be able to access your CD-ROM drive. It will appear one drive letter after your last drive partition. If your hard disk partitions are C: and D:, the CD-ROM drive will be E:.

Note that these procedures require that you find your CD-ROM driver and copy it onto the startup disk. If you can't find the driver or have a SCSI hard disk (which uses different types of drivers), I recommend you borrow a copy of a Windows 98 or later version startup disk. These startup disks already include a series of drivers that work with virtually any CD-ROM drive on the market, even SCSI versions.

After you have successfully created a startup disk with the CD-ROM drivers (or have the Win98 startup disk), insert the Windows CD-ROM in your CD/DVD drive. After booting from the startup floppy, change to the CD/DVD drive letter. Then at that prompt, run the **SETUP** command. This starts the Windows installation program. From here, you can follow the prompts to install Windows as you see fit. This procedure can be somewhat lengthy, so be prepared to spend some time. You will be installing not only Windows, but also the drivers for any hardware detected during the installation process.

Whether you are booting from floppy or CD, I recommend copying the Windows files to your hard disk and actually running the installation from the hard disk and not the CD. This is helpful in the future should you want to reinstall or install any additional parts of Windows because it will then work directly from the hard disk and you won't be asked to insert the CD.

To do this, first check the CD for the directory containing the ***.CAB** files and copy them to the hard disk. For example, using Windows 98 it would go something like this:

```
copy E:\WIN98\*. * C:\WIN98 /S
```

This copies all the files from the WIN98 directory on the CD-ROM (E: drive in this example) to the hard disk and places them in a directory called WIN98. Then, you can remove the CD (it is no longer needed) and run the installation directly from the hard disk by entering the following commands:

```
C:
CD\
C:\WIN98\SETUP
```

These commands change you to drive C:, place you in the root directory, and then run the Windows **SETUP** program to start the installation. From there, the menu-driven Windows installation routines guide you. If you are using a different version of Windows, merely change the directories used in the previous example to the appropriate directories for your version of Windows.

Note

If you want to create a bootable CD containing your Windows installation files, refer to [Chapter 11](#), "Optical Storage." For more information about installing CD/DVD drives, refer to [Chapter 12](#).

After Windows is installed, you can install any additional drivers or application programs you want. At this point, your system should be fully operational.

Note

If you prefer to install a version of Linux or other non-Windows operating system, follow the instructions given for the particular distribution you are using.

Installing Important Drivers

After installing the operating system, the first thing you need to do is install drivers for devices where drivers were not found on the Windows CD. This often includes things such as chipset drivers for your motherboard, drivers for newer video cards, USB 2.0 drivers, and more. Of these, the motherboard chipset drivers are the most critical and should be installed first. A CD containing these drivers should have been included with your motherboard; insert this disc and follow the prompts to install the chipset drivers. Then install other drivers, such as video, network, modem, and so on.

Disassembly/Upgrading Preparation

After you've built your system, you probably will have to open it again sometime to perform a repair or an upgrade. Before you power off the system for the last time and begin to open the case, you should learn and record several things about your computer. Often, when working on a system, you intentionally or accidentally wipe out the CMOS Setup information. Most systems use a special battery-powered CMOS clock and a data chip that is used to store the system's configuration information. If the battery is disconnected, or if certain pins are accidentally shorted, you can discharge the CMOS memory and lose the setup. The CMOS memory in most systems is used to store simple things such as how many and what type of floppy drives are connected, how much memory is in the system, and the date and time.

A critical piece of information is the hard disktype settings. Most modern BIOSs have an autodetect feature that reads the type information directly from the drive. I recommend you set the drive type to Auto, which automatically sets all the necessary parameters for you. With older BIOSs you must explicitly tell the system the parameters of the attached hard disk. Therefore, you need to know the current settings for cylinders, heads, and sectors per track.

If you do not enter the correct hard disktype information in the CMOS Setup program, you will not be able to access the data on the hard disk. I know of several people who lost some or all of their data because they did not enter the correct type information when they reconfigured their systems. If this information is incorrect, the usual results are a missing operating system error message when the system starts and the inability to access the C: drive.

Some people think that it's possible to figure out the parameters by looking up the particular hard disk in a table. (I have included a table of popular hard disk drive parameters in the Technical Reference on the disc. This table has proven to be useful to me time and time again.) Unfortunately, this method works only if the person who set up the system originally entered the correct parameters. I have encountered a large number of systems in which the hard disk parameters were not entered correctly; the only way to regain access to the data is to determine, and then use, the same incorrect parameters that were used originally. As you can see, no matter what, you should record the hard disk information from your setup program.

Most systems have the setup program built right in to the ROM BIOS software. These built-in setup programs are activated by a key sequence usually entered during the POST. Most systems show a prompt on the screen during the POST indicating which key to press to enter the BIOS Setup.

The major vendors have standardized on these following keystrokes to enter the BIOS Setup:

- *AMI BIOS*. Press Del during POST.
- *Phoenix BIOS*. Press F2 during POST.
- *Award BIOS*. Press Del or Ctrl+Alt+Esc during POST.
- *Microid Research BIOS*. Press Esc during POST.

If your system does not respond to one of these common keystroke settings, you might have to contact the manufacturer or read the system documentation to find the correct keystrokes to enter setup.

Some unique ones I have encountered are as follows:

- *IBM Aptiva/Valuepoint*. Press F1 during POST.
- *Older Phoenix BIOS*. Boot to a safe mode DOS command prompt, and then press Ctrl+Alt+Esc or Ctrl

+Alt+S.

- *Compaq*. Press F10 during POST (does not apply to all Compaq models).

◀◀ See "[Running or Accessing the CMOS Setup Program](#)," p. [443](#).

After you're in the BIOS Setup main screen, you'll usually find a main menu allowing access to other menus and submenus offering various sections or screens. When you get the setup program running, record all the settings. The easiest way to do this is to print it. If a printer is connected, press Shift+Print Screen; a copy of the screen display will be sent to the printer. Some setup programs have several pages of information, so you should record the information on each page.

Many setup programs allow for specialized control of the particular chipset used in the motherboard. These complicated settings can take up to several screens of information all should be recorded. Most systems return these settings to a BIOS default if the CMOS battery is removed, and you lose any customized settings you might have changed. See [Chapter 5](#) for more information on the BIOS settings.

Chapter 21. PC Mods: Overclocking and Cooling

Modifying, or *modding*, computer systems has been going on since even before the advent of the PC. In fact, because most of the early personal computers were either made from kits or entirely home built, custom modifications were the norm. And because of that, few systems were exactly alike. Even when fully functional personal computers and, more specifically, PCs came rolling off assembly lines in mass-produced fashion, people still found ways to make their own system different from all the others.

Computer modifications are usually designed to increase or improve performance or functionality in some way, but they can also be purely cosmetic in nature, or some combination of both. Because I am definitely more into function than form, I emphasize performance- or functionality-enhancing modifications in this chapter.

One of the primary modifications you can perform on a system is to make it run faster, which is usually called *overclocking*. When chips run faster, they run hotter, so cooling upgrades and modifications usually go hand-in-hand with overclocking. Systems that run cool tend to be more stable and more reliable, so even if you don't overclock your system, ensuring that it runs cool is essential for trouble-free operation. Anytime overclocking is discussed, cooling is certain to be involved because increasing the speed of a system also increases the cooling requirements. Many systems are not properly configured for good cooling even at their standard speeds, much less when overclocked.

New interfaces bring new connectors to the PC, and many of these are more useful on the front of the system rather than in the back. Bringing modern interfaces to the front panel; adapting newer drives for different form factors; and adding windows, vents, and fans are all modifications that can be made to a chassis or case to improve or update it to handle the latest hardware.

Finally, you can perform purely cosmetic modifications, such as custom painting or internal lighting, which can make your system stand out from the rest. I cover the functional modifications in this chapter, with sound engineering principles applied such that you can either modify an existing system correctly or purchase new components with the desired features already integrated.

Overclocking

One of the most popular performance-enhancing modifications of all time is overclocking, which can be defined as running all or part of the system faster than it was originally rated or intended to run. Overclocking is usually applied to the processor, but it can also be applied to other components in the system, including memory, video cards, bus speeds, and more.

Overclocking PCs dates all the way back to the original 4.77MHz IBM PC and 6MHz AT systems of the early 1980s. In fact, IBM made overclocking the AT easy because the quartz crystal that controlled the speed of the processor was socketed. You could obtain a faster replacement for about a dollar and easily plug it in. The first several editions of this book covered how to perform this modification in detail, resulting in a system that was up to 1.5 times faster than it started out. Modern systems allow overclocking without replacing any parts by virtue of simple and easy-to-change BIOS Setup options.

Quartz Crystals

To understand overclocking, you need to know how computer system speeds are controlled. The main component controlling speed in a computer is a quartz crystal. Quartz is silicon dioxide (SiO_2) in crystalline form. Oxygen and silicon are the most common elements on earth (sand and rock are mostly silicon dioxide), and computer chips are made mainly from silicon. Quartz is a hard, transparent material with a density of 2649 kg/m^3 (1.531 oz/in^3) and a melting point of 1750° C (3182° F). Quartz is brittle but with a little bit of elasticity, which is perhaps its most useful attribute.

In crystalline form, quartz can be used to generate regular and consistent signal pulses to regulate electronic circuits, similar to the way a metronome can be used to regulate music. Quartz crystals are used because they are *piezoelectric*, which is defined as having a property that generates a voltage when subjected to mechanical stress and that also generates mechanical stress when subjected to a voltage. Piezoelectricity was first discovered by Pierre and Jacques Curie in 1880, and it is the essential feature of quartz that makes it useful in electronic circuits.

The key to piezoelectricity is that when you twist, bend, deform, or simply apply pressure or stress to a quartz crystal, a small voltage is generated. This property is commonly used in sensors or transducers to detect pressure or sound waves. For example, the knock sensors used in virtually all modern automobile engines are based on quartz crystals that are sensitive to the vibrations produced in the engine block when detonation (uncontrolled burning of fuel) occurs. Because detonation can rapidly damage an engine, the engine management computer uses input from one or more knock sensors to retard the ignition timing, thus preventing engine damage. Some microphones and phonograph pickup devices also use quartz crystals for converting sound waves or the motion of the needle in the groove into a voltage.

Piezoelectricity works two ways, meaning that if a voltage is generated when you bend a crystal, likewise if you apply voltage to a crystal it bends (contracts, expands, or twists) in a similar fashion. Although the crystal is mostly brittle in nature, it is still somewhat elastic, such that any deformation tends to snap back and then occur again, resonating at a natural frequency as long as the voltage is present. Much like a tuning fork or the pipe in an organ, the natural resonant frequency depends on the size and shape of the crystal. In general, the smaller and thinner it is, the faster it vibrates.

The actual movement is exceedingly small, on the order of 68 nanometers (billionths of a meter) per centimeter, which in a normal crystal is only a few atoms in length. Although the movement is very small, it is also quite rapid, which means tremendous forces can be generated. For example, the surface acceleration of a 50MHz crystal can exceed five million times the force of gravity.

Crystal resonators are made from slabs of quartz sawed from raw quartz crystal stock. Although the stock can come from natural quartz, most crystals are made from synthetically grown quartz. The raw stock slabs are cut into squares, rounded, and ground into flat discs called *blanks*. The thinner the disc, the higher the resonant frequency; however, there are limits as to how thin the discs can be made before they break. The upper limit for fundamental mode resonators is approximately 50MHz. At that frequency, the discs are paper thin and are generally too fragile to withstand further grinding. Still, higher-frequency crystals can be achieved by using harmonics of the fundamental frequency, resulting in crystals of up to 200MHz or more. Even higher frequencies can be achieved by using frequency synthesizer circuits, which use a base crystal-generated frequency fed to a circuit that then generates multiples of frequency that can extend well into the gigahertz or terahertz range. In fact, crystal-based frequency synthesizer circuits are used to generate the high operating speeds of modern PCs.

The crystal packages, as well as the shape of the actual quartz crystals inside the packages, can vary. The packages are usually a metal can that is either cylindrical or oblong in shape, but they can also have other shapes or be constructed of plastic or other materials (see [Figure 21.1](#)).

Figure 21.1. Crystal packages of varying shapes.

The sliver of quartz inside the package is normally disc shaped, but it is shaped like a tuning fork in some examples. [Figure 21.2](#) shows a cylindrical crystal package with the cover removed, exposing the tuning forkshaped sliver of quartz inside.

Figure 21.2. Crystal interior showing the quartz tuning fork.

Most crystals use a disc-shaped sliver of quartz as a resonator. The disc is contained in a hermetically sealed evacuated enclosure.

[Figure 21.3](#) shows the interior view of a typical crystal with a disc-shaped resonator inside.

Figure 21.3. Crystal interior showing disc-shaped quartz resonator.

The quartz disc inside has electrodes on each side, allowing a voltage to be applied to the disc. The details are shown in [Figure 21.4](#).

Figure 21.4. Disc-shaped quartz resonator details.

Walter G. Cady was the first to use a quartz crystal to control an electronic oscillator circuit in 1921. He published his results in 1922, which led to the development of the first crystal-controlled clock by Warren A. Marrison in 1927. Today, all modern computers have multiple internal oscillators and clocks, some for controlling bus and processor speeds and at least one for a standard time of day clock.

Overclocking History

Overclocking has been around since the beginning of computing. As long as there have been computers, there have been people trying to make them run faster. I began overclocking PCs back in the early 1980s, using a variety of devices on the market. The easiest system to overclock was the original IBM AT, which used a socketed crystal to run the processor. Two versions of the XT were available one that used a 12MHz crystal and one that used a 16MHz crystal. The timer chip divided the crystal speed by 2, resulting in processor speeds of 6MHz and 8MHz.

A popular trick at the time was to pop the 12MHz or 16MHz crystals out of their sockets and replace them with 18MHz or 20MHz crystals, which sped up the systems to 9MHz or 10MHz. Back in 1984, I was able to purchase crystals for as little as \$1 each from RadioShack, and they could be changed in seconds. In my 6MHz system, I was able to use an 18MHz crystal to get the system to run at 9MHz. That was a 50% increase in speed for about \$1! I had tried a 20MHz crystal (10MHz speed), but the system would not boot up at that speed, so I had to drop back to the 18MHz (9MHz speed) crystal instead.

Taking this further, some companies released variable frequency oscillators, which basically amounted to a variable speed crystal you could use to replace the fixed stock crystal. A control panel was then mounted on the back of the system, which had an adjustment knob you could use to change the system speed. The most sophisticated of these was the XCELX, which allowed you to adjust the original IBM AT from 6.5MHz to 12.7MHz. [Figure 21.5](#) shows the XCELX, which dated from 1985.

Figure 21.5. The XCELX frequency adjuster, a "throttle" that could be used to speed up the IBM AT.

The instructions told you to turn up the throttle until the system crashed and then back down a notch or two. How fast a given system would run depended on all the specific components contained within.

Tip

One problem in the vintage IBM AT and XT-286 systems was that the clock speed was checked during the Power On Self Test (POST). This caused problems if you replaced the socketed clock crystal in these systems for a cheap and easy speedup. In IBM AT and XT-286 systems, the POST checked the system refresh rate (clock speed) to ensure that it was 6MHz or 8MHz, depending on which system you had. A marginally faster or slower rate caused the test to fail and resulted in a POST error of one long and one short beep, followed by a halt (**HLT**) instruction.

To eliminate the test and enable a faster-than-normal clock rate, you had to patch the instruction at the proper location from a 73h (JAEJump if Above or Equal) to an EBh (JMPJump unconditionally). When this instruction was changed, the test never fell into the error routine, no matter how fast the rate. The JAE instruction occurred at F000:05BC in IBM AT systems with the 06/10/85 or 11/15/85 ROM BIOS versions and at F000:05C0 in XT-286 systems. Note that the original IBM AT system with the 01/10/84 BIOS did not have this test. By creating a new set of ROM chips with this instruction changed by an EPROM programmer, you could eliminate this speed check and enable faster clock rates.

Few people are interested in overclocking systems that are more than 20 years old, but it is interesting to see that hotrodding PCs has been around for as long as PCs themselves have existed!

Modern PC Clocks

A modern PC has at least two crystals on the motherboard; the main crystal is used to control the speed of the motherboard and motherboard circuitry, and the other is used to control the real time clock (RTC). The main crystal is always 14.31818MHz (it might be abbreviated as 14.318 or just 14.3), and the RTC crystal is always 32.768KHz.

Why 14.31818MHz?

The original 1981 vintage IBM PC ran at 4.77MHz, a speed derived by taking a 14.31818MHz crystal and using a divider circuit to divide the frequency by 3 to get 4.77MHz. The same 14.31818MHz crystal was also divided by 4 to get 3.58MHz, which is the exact frequency needed for the NTSC color video modulation signal required to be compatible with color TV. Another circuit divided the crystal frequency by 12 to get 1.193182MHz, which was used by an 8253 programmable three-channel 16-bit interval timer/counter chip. Each channel could be used to take an input clock signal and produce an output signal by dividing by an arbitrary 16-bit number. Channel 0 was used to make the time of day clock ticks. It was programmed by the BIOS to call INT 08h every 65,536 ticks, which was about 18.2 times per second (or about every 55 milliseconds). The software routines linked to INT 08h caused the time of day clock to be updated and could also chain to any other activities that needed to be done periodically. Channel 1 was used to tell the DMA to refresh the dynamic RAM every 72 cycles (about 15 microseconds), and channel 2 was used to make an audio signal for the speaker (beeps) different tones could be made by changing the divisor.

As a testament to computer evolution, all modern PCs are still controlled by a 14.318MHz crystal! The crystal, in conjunction with a frequency timing generator chip, is used to derive virtually all the frequencies used on a modern motherboard by the CPU bus, PCI bus, AGP bus, memory bus, and USB.

PCs don't run at 14.318MHz, so how can a crystal of that speed be used to control their speed? And what happens when you install a different processor? How does the system adjust the bus and other speeds to accommodate the new chip? The answer is that a special chip called a frequency timing generator (FTG) or frequency synthesizer is used in conjunction with the crystal to derive the actual speeds of the system. [Figure 21.6](#) shows a portion of a motherboard with an FTG chip with a 14.318MHz crystal below it.

Figure 21.6. Frequency synthesizer chip with a 14.318MHz crystal.

The RTC uses its own separate 32.768KHz crystal to count time independent from the speed of the system. [Figure 21.7](#) shows a 32.768KHz crystal next to a chipset South Bridge or I/O controller hub, which contains the RTC circuitry and CMOS RAM.

Figure 21.7. Chipset South Bridge (I/O controller hub) incorporating an RTC, along with the 32.768KHz clock crystal.

Most frequency synthesizer chips used on PC motherboards are made by Integrated Circuit Systems (www.icst.com) or Cypress Semiconductor (www.cypress.com; formerly International Microcircuits Inc [IMI]). These chips use phased locked loop (PLL) circuitry to generate synchronized processor, PCI, AGP, and other bus timing signals that are all derived from a single 14.318MHz crystal. The crystal and frequency synthesizer chip are usually situated near the processor and main chipset component of the motherboard.

The amazing thing about these chips is that most of them are programmable and adjustable, so they can change their frequency outputs via software, which results in the system running at different speeds. Because all CPUs are based on the speed of the CPU bus, when you change the CPU bus speed generated by the frequency synthesizer chip, you can change the speed of your processor. Because the PCI, AGP, and memory buses are often synchronized with the speed of the processor bus, when you change the processor bus speed by a given percentage, you also change the speed of those other buses by the same percentage. The software to accomplish this is built in to the BIOS Setup menus of most modern motherboards.

Overclocking Tips

Most modern motherboards automatically read the CPU and memory components to determine their proper speed, timing, and voltage settings. Originally, these settings were controlled by jumpers and switches on 486 and Pentium boards, but in most modern boards you can enter the BIOS Setup to change these settings to manual and then use the menu options in the BIOS Setup to alter the speed of the system. Because such alterations can make the system unstable, most systems are designed to boot into the BIOS Setup at a default low speed so you are not locked out from making changes in the future. This makes overclocking as simple as changing a few menu options and then rebooting to test the selections you've made.

The concept for overclocking is simple: You change the settings to increase the speed of the processor, memory, buses, and so on until the system becomes unstable. Then you can go back in and reduce the settings until it is stable again. In this manner, you find the maximum sustainable speed for a system. Because each processor is different, even ones with the same ratings can end up allowing different maximum stable speeds.

The first Pentium 4 chips based on the Prescott core were 112 square mm and made on 300mm wafers, resulting in a maximum of 631 chips per die. Typically, many of those chips won't pass testing, but let's say that 80% (or 504 chips) do. Intel initially sold the Prescott version at speeds from 2.4GHz through 3.4GHz. This means that all the 500+ chips coming off the wafer are potentially 3.4GHz (or faster) chips. They are tested after manufacture and sorted into bins by how fast they can actually run.

Early in manufacturing a given processor design, they have more running at the lower speeds and fewer capable of achieving the maximum settings. This is why the fastest chips are the most expensive generally fewer of them pass the testing at that speed. Eventually, however, as they tweak the manufacturing processes and chip design, more and more of the finished chips pass the higher speed tests. But lower-speed chips are priced less and sell more, so Intel might have to dip into the faster bins and mark those chips at the lower speeds to fill the larger number of orders.

Essentially what I'm saying is that Intel sets out to make all the chips on the wafer identically and tries to make them so they will all run at the highest speed. If you purchase one of the lesser-rated chips, you really have the same chip as the higher-rated versions; the difference is the higher-rated ones are guaranteed to run at the higher speeds, whereas the lower-rated ones are not. That is where overclockers come in.

Users who overclock their systems purchase lower-rated chips and essentially do their own testing to try to run them at the higher speeds. They can also start with the highest-rated chips and see whether they can run them even faster, but success there is much more limited. The most successful overclocking is always with the lowest-rated speed of a given design, and those chips are also sold for the lowest price. In other words, statistically you might be able to find many of the lowest-speed grade chips that are capable of running at the highest-speed grade (because they are essentially identical during manufacture); however, if you start with the highest-speed grade, you might be able to increase the speed only a very small percentage.

The key to remember is that a difference exists between the rated speed of a chip and the actual maximum speed at which it runs. Manufacturers such as Intel and AMD have to be conservative when they rate chips, so a chip of a given rating is always capable of running at least some margin of speed faster than the rating the question is how much faster? The only way to know that is by testing chips individually.

Bus Speeds and Multipliers

Because modern processors run at a multiple of the motherboard speed and the selected multiple is locked within the processor, all you can do to change speeds is to change the processor bus speed settings. The processor bus is also called the CPU bus, front side bus (FSB), or processor side bus (PSB), all of which are interchangeable terms.

For example, I built a system that uses an Intel Pentium 4 3.2E processor, which typically runs at 3200MHz on an 800MHz CPU bus. Thus, the processor is locked to run at four times the speed of the CPU bus. I was able to increase the CPU bus speed from 800MHz to 832MHz, which meant the processor speed increased from 3200MHz to 3328MHz, which is 128MHz faster than the rating. This took all of about 60 seconds to reboot, enter the BIOS Setup, make the changes in the menu, save, and reboot again. This was only a 4% increase in overall speed, but it didn't cost a penny and the system seemed to be just as stable as it was

before.

Many motherboards allow changes in speed of up to 50% or more, but a processor rarely sustains speeds that far above its rating without locking up or crashing. Also note that, by increasing the speed of the processor bus, you are increasing the speed of the memory bus, PCI bus, and AGP bus by the same percentage. Therefore, if your memory is unstable at the higher speed, the system will still crash, even though the processor might have been capable of sustaining it. The lowest common denominator prevails, which means your system will run faster only if all the components are up to the challenge.

Many motherboards allow voltage changes to be made for components such as processors, memory, and video cards. Be careful when making these changes because you can damage a component with improper voltage. Still, many overclockers have found that by tweaking the voltage up or down a tenth or so at a time, they can get a system to run more stable than had otherwise been possible.

Cooling

Heat can be a problem in any high-performance system. The higher-speed processors consume more power and therefore generate more heat. The processor is usually the single most power-hungry chip in a system, and in most situations, the fan inside your computer case is incapable of handling the load without some help.

Heatsinks

At one time, a *heatsink*, a special attachment for a chip that draws heat away from the chip, was needed only in systems in which processor heat was a problem. However, starting with the faster Pentium processors in the early 1990s, heatsinks have been a necessity for every processor since.

A heatsink works like the radiator in your car, pulling heat away from the engine. In a similar fashion, the heatsink conducts heat away from the processor so it can be vented out of the system. It does this by using a thermal conductor (usually metal) to carry heat away from the processor into fins that expose a high amount of surface area to moving air. This enables the air to be heated, thus cooling the heatsink and the processor as well. Just like the radiator in your car, the heatsink depends on airflow. With no moving air, a heatsink is incapable of radiating the heat away. To keep the engine in your car from overheating when the car is not moving, auto engineers incorporate a fan. Likewise, a fan is always incorporated somewhere inside your PC to help move air across the heatsink and vent it out of the system. In some name-brand systems, the fan included in the power supply is enough when combined with a special heatsink design; in most cases, though, an additional fan must be attached directly over the processor to provide the necessary levels of cooling. Case fans are also typical in recent systems to assist in moving the hot air out of the system and replacing it with cooler air from the outside.

The heatsink is clipped or, rarely today, glued to the processor. A variety of heatsinks and attachment methods exist. [Figure 21.8](#) shows various passive heatsinks and attachment methods.

Figure 21.8. Passive heatsinks for socketed processors showing various attachment methods.

Tip

According to data from Intel, heatsink clips are the number-two destroyer of motherboards (screwdrivers are number one). When installing or removing a heatsink that is clipped on, be sure you don't scrape the surface of the motherboard. In most cases, the clips hook over protrusions in the socket and, when installing or removing the clips, scratching or scraping the surface of the board right below where the clip ends attach is very easy. I like to place a thin sheet of plastic underneath the edge of the clip while I work, especially if board traces that can be scratched are in the vicinity.

Heatsinks are rated for their cooling performances. Typically, the ratings are expressed as a resistance to heat transfer in degrees centigrade per watt ($^{\circ}\text{C}/\text{W}$), where lower is better. Note that the resistance varies according to the airflow across the heatsink.

Active Heatsinks

To ensure a constant flow of air and more consistent performance, many heatsinks incorporate fans so they don't have to rely on the airflow within the system. Heatsinks with fans are referred to as *active* heatsinks (see [Figure 21.9](#)). Active heatsinks have a power connection. Older ones often used a spare disk drive power connector, but most recent heatsinks plug in to dedicated heatsink power connections found on the newer motherboards.

Figure 21.9. Active heatsink suitable for a Pentium 4 processor using Socket 478.

The Pentium 4 design uses two cams to engage the heatsink clips and place the system under tension. The force generated is 75 lbs., which produces a noticeable bow in the motherboard underneath the processor. This bow is normal, and the motherboards are designed to accommodate it. The high amount of force is necessary to prevent the heavier heatsinks from pulling up on the processor during movement or shipment of the system, and it ensures a good bond for the thermal interface material (thermal grease).

[Figure 21.10](#) shows the design used on most Athlon 64 and 64 FX processors, featuring a cam and clip assembly on one side. Similar to the Pentium 4 double-cam assembly shown earlier, this design puts 75 lbs. of force between the heatsink and the processor. Bowing of the motherboard is prevented in this design by the use of a special stiffening plate underneath the motherboard. The heatsink retention frame actually attaches to this plate through the board. The stiffening plate and retention frame normally come with the motherboard, but the heatsink with fan and the clip and cam assembly all come with the processor.

Figure 21.10. Active heatsink suitable for an Athlon 64, Athlon 64 FX, or Opteron processor using Socket 754.

Tip

One of the best reasons to use the motherboard-based power connectors for the fan is that most recent system BIOS setup programs can display the fan performance and report it to a system monitoring program. Because some processors—particularly older Athlon processors—can be destroyed in a few moments by a malfunctioning processor heatsink fan, this feature can help prevent a disaster inside your system.

Active heatsinks use a fan or other electric cooling device that requires power to run. Active heatsinks also require power and usually plug in to the motherboard CPU fan connector (or, in older systems, a disk drive power connector). If you do get a fan-type heatsink, be aware that some on the market are of very poor quality. The bad ones have motors that use sleeve bearings, which freeze up after a very short life. I recommend only fans with ball-bearing motors, which last about 10 times longer than the sleeve-bearing types. Of course, they cost more—but only about twice as much, so you'll save money in the long run. Expect to pay anywhere from \$25 to \$60 for a high-quality active fan heatsink, unless you purchase a "boxed" processor that includes a factory-supplied, high-quality active heatsink in the box with the chip. You'll invariably pay the most for the most efficient, best-cooling active heatsinks, and those overclockers who swear by these devices usually also believe that the extra expense is worthwhile.

[Figure 21.11](#) shows an active heatsink arrangement designed for a Socket 939 or LGA 775 processor that comes with bracketing to accommodate both designs.

Figure 21.11. The Scythe Ninja works well as a purely passive cooler, or it can have a 120mm fan mounted to one of its sides. (Photo courtesy of Mike Chin/*SilentPCReview.com*)

With the wide variety of processor speeds and construction on the market today, you also need to match the processor speed to the speed range of the heatsink you plan to use. Heatsinks made for faster processors have a larger cooling area, and an increasing number of them use a copper conducting plate or are made of solid copper rather than less-conductive aluminum. The cooling solution from Arctic Cooling depicted in [Figure 21.12](#) is designed to be compact and quiet.

Figure 21.12. The Arctic Cooling Super Silent 4 Ultra TC CPU fits socket 478 CPUs. *(Photo courtesy of Mike Chin/SilentPCReview.com.)*

Passive heatsinks are basically aluminum-finned radiators that rely on airflow from an external source. Passive heatsinks don't work well unless there is some airflow across the fins, usually provided by a chassis-mounted fan that sometimes features a duct to direct airflow directly through the fins on the heatsink. Integrating a passive heatsink is more difficult because you must ensure that the airflow comes from some other source; however, this can be more reliable and very cost effective if done correctly. This is why many of the larger name systems, such as those from Dell and Gateway, often use passive heatsinks with a ducted chassis fan. Systems built by individuals or smaller companies that don't have the ability to engineer a custom passive cooling solution should instead rely on an active heatsink with a built-in fan. An active heatsink provides a more certain cooling solution regardless of other airflow characteristics in the system.

Processors sold as boxed or retail versions from Intel and AMD include high-quality active heatsinks designed to work under the worst possible ambient conditions (see [Figure 21.13](#)). One of the main reasons I recommend purchasing boxed processors is that you are guaranteed to get a high-quality heatsink with the processor, one that is designed to cool the processor under the worst conditions and which should last the life of the system.

Figure 21.13. A passive heatsink and supports used with Pentium II/III SECC processors.

Heatsink Clamping Force

The FC-PGA packaging used by some processors is so named because the raw processor die is placed upside down on top of the chip. This enables the heatsink to come in direct or near-direct contact with the die, resulting in the maximum heat transfer to the sink. Unfortunately, some problems have occurred that have forced chip makers to modify their designs.

The main problem is one of force too much and unevenly applied. Intel specifies a moderate 20-pound static load force for the heatsink on an FC-PGA die, whereas AMD specified a higher 30-pound static loading force for the spring clip to attach the heatsink on the Athlon, Duron, and Athlon XP processors. This has unfortunately resulted in many processors being damaged during heatsink installation. The reason for the

higher static load on the AMD chips is to maximize the thermal transfer. Because the die rises up from the surface of the chip, the heatsink contacts only the die itself and overhangs in all directions. If, while installing the heatsink, you apply too much force to one corner or edge of the heatsink, you place an uneven force on the die and it cracks with a loud snap. This, of course, destroys the chip, and such damage is normally not warranted by the chip manufacturer because it is considered improper handling and not a manufacturer defect. Although this cracking problem affected both AMD and Intel processors, it was much more of a problem with the AMD chips due to the higher force from the heatsink clip specified by AMD. These problems have caused many vendors to provide a warranty for the processor only if it is sold with a motherboard and preinstalled by the vendor.

To correct these problems, AMD and Intel both have come up with solutions. AMD first began installing rubber pads near each of the four corners of the chip to help support the overhanging parts of the heatsink and prevent uneven forces that result in cracking. Unfortunately, even with these pads, you can still crack the die if you install the heatsink in a tilted or cockeyed position. To avoid damage, the Athlon 64 uses a different heatsink mounting method that secures the heatsink to the motherboard with a clip that is screwed into place.

Intel and AMD now install a metal cap called an integrated heat spreader (IHS) over the die of its newer processors. This protects the die from direct force and helps spread out the thermal contact point between the processor and heatsink. Most of the IHS-equipped chips allow up to a 100-pound static force from the heatsink and are virtually immune to the cracking problems related to improper heatsink installation. Intel's current heatsink designs for processors with integrated heat spreaders use a clamping force of 75 lbs. nominal on the processor. All Pentium 4, Celeron 4, Pentium III/Celeron Tualatin (0.13-micron), and AMD Athlon 64 and 64 FX processors include this (see [Figure 21.14](#)). In general, FC-PGA with the integrated heat spreader is called FC-PGA2.

Figure 21.14. Side view of an FC-PGA2 processor showing the integrated heat spreader mounted on top of the die.

If you are installing an AMD or Intel processor that does not use an IHS metal cap, be extra careful to keep the heatsink flat and level with the surface of the die while attaching or removing the heatsink clip.

Heatsink Ratings and Calculations

When cooling a processor, the heatsink transfers heat from the processor to the air. This capability is expressed in a figure known as *thermal resistance*, which is measured in degrees Celsius per watt (C/W). The lower the figure, the lower the thermal resistance and the more heat the heatsink can remove from the CPU.

To calculate the heatsink required for your processor, a formula can be used:

$$R_{\text{total}} = T_{\text{case}} - T_{\text{inlet}} / P_{\text{power}}$$

T_{case} is the maximum allowable CPU case temperature, T_{inlet} is the maximum allowable inlet temperature to the CPU heatsink, and P_{power} is the maximum power dissipation of the processor. For example, the Pentium 4 3.4E (Prescott) processor is rated for a maximum operating temperature of 73° C and a maximum heatsink inlet temperature of 38° C, and it has a maximum thermal output of 103 watts. This means the heatsink required to properly cool this chip needs to be rated $73^{\circ}\text{C} - 38^{\circ}\text{C} / 103\text{W} = 0.34^{\circ}\text{C/W}$. This figure includes the resistance of both the thermal interface material (thermal grease) as well as the heatsink itself, so if you used a thermal grease with a known resistance of 0.01° C/W, the heatsink would need to be rated at 0.33° C/W or less.

Another useful formula can be used to describe processor power:

$$P_{\text{power}} = C \times V^2 \times F$$

P_{power} is the maximum power output of the processor, C is the capacitance, V^2 is the voltage squared, and F is the frequency. From this you can see that if you double the frequency of a processor, it will consume twice as much power, and if you double the voltage, it will consume four times as much power. Consequently, if you lower the voltage by half, it will consume only one fourth the power. These relationships are important to consider if you are overclocking your processor because a small increase in voltage will have a much more dramatic effect than a similar increase in speed.

In general, increasing the speed of a processor by 5% increases the power consumption by only the same amount. Using the previous heatsink calculation, if the processor speed was increased by 5%, the 103W processor would now draw 108.15W and the required heatsink rating would go from 0.34° C/W to 0.32° C/W, a proportional change. In most cases, unless you are overclocking to the extreme, the existing heatsink should work. As a compromise, you can try setting the voltage on manual and dropping it a small amount to compensate, thereby reducing the power consumption. Of course, by dropping the voltage, the CPU might become unstable, so this is something that needs to be tested. As you can see, changing all these settings in the interest of overclocking can take a lot of time when you consider all the testing required to ensure everything is working properly. You have to decide whether the rewards are worth the time and energy spent on setting it up and verifying the functionality.

Note that most professional heatsink manufacturers publish their °C/W ratings, whereas many of what I call the "boutique" heatsink vendors do not. In many cases the manufacturers of many of the more extreme heatsinks don't do the testing that the professional manufacturers do and are more interested in the looks than the actual performance.

Installing a Heatsink

To have the best possible transfer of heat from the processor to the heatsink, most heatsink manufacturers specify some type of thermal interface material to be placed between the processor and heatsink. This typically consists of a ceramic, alumina, or silver-based grease but can also be in the form of a special pad or even a type of double-stick tape. Some are called *phase-change* material because they change viscosity (become thinner) above certain temperatures, enabling them to better flow into minute gaps between the chip and heatsink. In general, thermal greases offer higher performance than phase-change materials, but because they always have a lower viscosity, they flow more easily, can be messy to apply, and (if too much is used) can spill from the sides onto the socket and motherboard.

No matter what type you use, a thermal interface aid such as thermal grease or phase-change material can improve heatsink performance dramatically compared to installing the heatsink dry. Thermal interface materials are rated by thermal conductance (in which case higher is better) or thermal resistance (in which

case lower is better). Unfortunately, several industry-standard rating scales are used to measure performance, often making product comparisons difficult. Some measure the thermal conductivity; others measure the thermal resistance; and the scales used can vary greatly. The most commonly reported specification is thermal resistance in degrees centigrade per watt ($^{\circ}\text{C}/\text{W}$) for an interface layer 0.001" thick and 1 square inch in size. For a given material, the thinner the interface layer or the larger the area, the lower the resistance. In addition, due to other variables such as surface roughness and pressure, it is often impossible to directly compare different materials even if they appear to use the same ratings scale.

As a means of offering some sort of comparison, let's look at the effect on processor temperatures by using thermal interface materials of different specifications. Currently, the highest thermal output processor is the Pentium 4 3.4E, which is rated at 103W thermal output with a surface area on the heat spreader of 1.5 square inches. Using thermal interface materials of different C/W specifications, [Table 21.1](#) shows the rise in temperature that will result.

Table 21.1. Thermal Interface Material Resistance Versus CPU Temperature Rise for a 103W Pentium 4 Processor

Thermal Rating ($^{\circ}\text{C}/\text{W}$)	Temperature Rise ($^{\circ}\text{C}$)
0.000	0.00
0.005	0.34
0.010	0.69
0.020	1.37
0.030	2.06
0.040	2.75
0.050	3.43
0.060	4.12
0.070	4.81
0.080	5.49
0.090	6.18
0.100	6.87

Most of the better thermal greases are rated from 0.005 to 0.02 C/W per square inch, which would result in a rise of between 0.34° and 1.37° C. Even if there was a "perfect" thermal grease available, you would reduce the CPU temperature by only less than 2° over most of the products currently on the market. I've seen actual tests of multiple brands of thermal greases, and in most cases the differences in temperature readings between different brands are insignificant. For that reason, I generally don't get too excited about different brands of thermal grease; most of the premium products on the market have surprisingly similar performance.

You can purchase thermal grease in small single-use tubes or larger versions that can service multiple processor installations. Most of the recommended thermal greases include alumina or silver, which offer the lowest thermal resistances. Silver is generally the best but is significantly more expensive with real-world differences that are very slight. One brand (Arctic Silver) has even developed a following sufficient to cause others to counterfeit the product and name. The important thing to note is that, based on calculations as well as in tests I've seen, there has been only a couple of degrees difference in CPU temperature under full load when substituting one brand of thermal grease for another. If you want the best, choose a compound with embedded silver. The next best option is alumina and then the less expensive (and somewhat less effective) ceramic-based greases.

[Figure 21.15](#) shows the thermal interface pad or grease positioned between the processor and heatsink.

Figure 21.15. Thermal interface material helps transfer heat from the processor die to the heatsink.

Most systems on the market today use improved motherboard form factors (shapes) called ATX or BTX. Systems made from these types of motherboards and cases allow for improved cooling of the processor because the processor is repositioned in the case and room is provided for a chassis fan or even a duct to direct airflow over the processor. Most of these cases also feature one or more secondary fans to further assist in cooling. The larger case-mounted fans, especially those with ducts mounted directly over the processor, add to the cooling capability of the system.

◀◀ See "[BTX](#)" p. [238](#).

Liquid Cooling

One of the more extreme methods for cooling a PC is to use some form of liquid cooling. Liquids have a much greater thermal carrying capacity than air, and as processors run hotter and hotter, it can be advantageous or even necessary in some situations to use a form of liquid cooling to dissipate the extreme levels of heat generated, especially in smaller or more confined spaces.

Several forms of liquid cooling are available, including

- Heat pipes
- Water cooling
- Refrigeration

Each of these uses a liquid or vapor to absorb the heat of the processor or other components and take that heat to a heat exchanger where it must eventually be dispersed to the air. So, all liquid cooling involves air cooling as well; it just removes the exchange of heat to the air to a remote place. Also, the heat exchanger (radiator) used can be much larger than what would fit directly on the processor or other chips, which is another reason liquid cooling offers much greater cooling capacity.

Of all the types of liquid cooling available, heat pipes are the only type that is practical and cost-effective in production-level PCs. Water cooling and especially refrigeration are limited to those who are pursuing extreme overclocking and are willing to pay the high prices and put up with all the drawbacks and disadvantages that come with these two options.

Heat Pipes

Heat pipes were invented by George Grover at the Los Alamos National Laboratory in 1963. In simplest terms, a *heat pipe* is a thermal conductor designed to efficiently move heat from one place to another.

A typical heat pipe consists of a hermetically sealed tube incorporating a fine wick structure lining the inner walls, with a hollow core in the center. When constructed, the tube is first completely evacuated of air, then partially filled with a special fluid, and then sealed. The type of fluid and remaining vacuum inside allow the fluid to boil at relatively low temperatures. When the pipe is heated at one end, the fluid changes phase from liquid to vapor, absorbing a tremendous amount of heat in the process. The vapor then travels through the hollow core to the other end of the heat pipe where it condenses, changing phase again back into a liquid and releasing a tremendous amount of heat in the process. The liquid then travels back to the original end through the wick structure via capillary action (see [Figure 21.16](#)).

Figure 21.16. Heat pipe interior structure and function.

Heat pipes work by causing a liquid to change phase into a gas to absorb heat and then by causing the gas to change phase back into a liquid to release heat. The energy required to change phase is called the *latent heat of evaporation*. For example, the latent heat of evaporation for water is about 540 cal/g. Most heat pipes use water, ammonia, and methanol. The specific liquid is selected based on the temperature range at which the pipe will work. Water normally boils at 100° C (212° F); however, inside a heat pipe, the pressure is reduced by a partial vacuum such that the boiling point is at room temperature. Because of the heat of evaporation, a heat pipe is generally 1010,000 times more thermally conductive than a solid copper rod of the same diameter and length.

Heat pipes cannot work alone. They need to be attached to the processor or other heat producing device at one end, and they must have some way of getting rid of the heat at the other end. Usually the condensing end is attached to a conventional heatsink, often with a fan. [Figure 21.17](#) shows one of the heat pipebased heatsinks used in the Shuttle line of small form factor systems.

Figure 21.17. Heat pipe system with four pipes for cooling a processor.

In this example, a fan would be mounted on the back panel blowing through the fins attached to the ends of the heat pipes.

Heat pipes have many advantages. Because they are sealed and have no moving parts, they don't require any maintenance and don't wear out. If properly designed, they can even withstand freezing, although they won't work properly until the liquid inside is thawed. Heat pipes are also very compact and are ideal for small form factor system designs. This is one reason almost all laptop computers have been cooled by heat pipes since the early 1990s.

Heat pipes are not only useful as a specific cooling solution, but can also be used to enhance conventional heatsinks. By embedding heat pipes inside a conventional heatsink, the thermal distribution within the heatsink is dramatically improved. [Figure 21.18](#) shows a heatsink with two heat pipes allowing for greater transfer of heat from the bottom to the top of the sink.

Figure 21.18. Heatsink with heat pipes for improved thermal distribution and performance.

Of all of the liquid cooling mechanisms, heat pipes have the most promise for future use in desktop computers.

Water Cooling

Water cooling is simple in concept but more complicated in reality. The idea is to circulate water over the processor or other components, thereby keeping them cool. The reality is a bit more difficult, making water cooling expensive, difficult to implement, and suitable only for extreme situations.

Water cooling involves several main components:

- *Water blocks.* Mounted on the processor and sometimes on the video card or chipset North Bridge, these are mostly blocks of metal with internal water passages and fittings to connect hoses.
- *Hoses and fittings.* These are used to interconnect all the components in the system.
- *Reservoir.* These are used to provide a sufficient amount of water to cool the components, as well as to cool the water for recirculation.
- *Pump.* A device used to move the water through the system.
- *Coolant.* The fluid, usually water, which is pumped through the system.

A diagram of a water cooling system using an external reservoir and pump is shown in [Figure 21.19](#).

Figure 21.19. Zalman water cooling system with external reservoir and pump.

Some systems use pumps and reservoirs that are internal to the PC or that are mounted on the top, sides, or back. Placing the pump and reservoir inside can be difficult because these components require additional room.

Although water cooling systems can provide a tremendous amount of cooling capacity, they can be troublesome to use and maintain. Their primary disadvantages are that they require a pump to move the water and, if the pump fails, the system overheats. In addition, the water tends to cause corrosion in the pump, water blocks, and reservoirs and can even be subject to problems such as algae growth or other contamination. Finally, every fitting is the source of a potential leak and, if water leaks inside the system, it can cause the entire system to short out and fail. Water cooling systems also have a maintenance drawback: Periodic maintenance is necessary to prevent problems.

Contamination and corrosion have been major problems for water-cooled systems. Many people used plain water in their early designs, which as anybody familiar with automobiles knows allows corrosion and contamination to occur in short order. Using an automotive-style coolant is the best solution for most water

cooling systems because the ethylene glycolbased coolants have additives that prevent corrosion and allow for long life. Still, the coolant should be periodically changed, and the water blocks, pump, and reservoir should be inspected for contamination and corrosion. Fittings should also be inspected for leaks periodically.

A good water cooling system can cost several hundred dollars, much more expensive than air cooling solutions or even heat pipes. They add a lot of visual appeal to a system; many systems use clear hoses and dyes to color the coolant for visual effect.

Due to the expense, maintenance required, potential for failure, and physical size of all the components, water cooling is best used in systems in which extreme overclocking or experimentation is the order. It will probably be a long time before water cooling reaches the point where it is used in commercially produced business or home PCs.

Refrigeration

On the extreme side of cooling, refrigeration enables the processor or other components to be reduced to below room temperature, allowing the extreme limits of overclocking and performance to be tested. When cooled to 40° C (also 40° F), a processor can be run at 33%100% faster than rated. Unfortunately, this speed comes at a price the refrigeration equipment is very expensive.

Because of the cost and expense, only a few companies have ever offered refrigerated chassis, mainly KryoTech and nVENTIV. In 1996, KryoTech introduced the first commercially available refrigerated PC. Unfortunately, due to costs and business concerns, it discontinued its chassis in 2002. nVENTIV, founded in 2000 as Chip-con, also introduced refrigerated chassis; today it has several models available. A cutaway view of the Mach II GT chassis and cooling module is shown in [Figure 21.20](#).

Figure 21.20. nVENTIV refrigerated cooling system cutaway.

The key to refrigerated cooling at 40° is the CPU block, which not only has to cool the chip, but also has to prevent condensation from forming. Special insulation and sealing are key to making this work. The nVENTIV CPU block is shown in [Figure 21.21](#).

Figure 21.21. nVENTIV refrigerated processor block.

You can purchase an entire chassis or just the lower cooling unit, which can be used to adapt any system to refrigerated cooling. These cooling solutions sell from about \$800 to \$1,200, so this is not an inexpensive proposition. Still, if you must have the absolute fastest system on the block and you live for the ultimate in overclocking, the only way to go is refrigerated cooling.

Thermally Advantaged Chassis

With processors generating more and more heat these days, some recent breakthroughs in chassis engineering and design have allowed for even the fastest processors to be properly cooled, without spending a fortune on an excessive amount of fans or an expensive cooling solution.

PC power supplies have always contained a fan. For many years, that single fan in the power supply bore the responsibility of cooling not only the supply, but also the entire system and even the processor. In fact, PCs prior to the 486 didn't even use heatsinks on the processor because they generated only a couple of watts of heat. Passive heatsinks first became a standard fixture on processors with the 486DX2 in 1992, which used up to 5.7W of power. Active heatsinks first appeared on the retail Pentium processors from Intel (called Overdrive processors) and became a standard fixture on boxed or retail Pentium II and III and AMD Athlon models in 1997 and later. Most chassis up until that time did not incorporate a cooling fan, except for what was in the power supply.

Chassis fans first became popular in OEM systems in the mid-1990s because they usually used less expensive passive heatsinks on the processor. It was more efficient to use a single chassis fan to cool both the chassis and the processor and save money by using a passive heatsink (without a fan) on the processor. By 2000, with the Pentium 4, many systems began using both an active processor heatsink (with a fan) and a chassis fan. Most modern systems include three fans: one in the power supply, one in the active heatsink on the processor, and one for the rear of the chassis. Some systems have additional fans, but three is the most common and most cost-effective design.

Unfortunately, with the most recently introduced processors reaching and even exceeding the 100W power level, it has become impossible for a standard chassis design to cool the system without resorting to adding more fans or using more exotic (and expensive) liquid cooling setups. A minor breakthrough in chassis design has occurred that can allow even processors consuming more than 100W to be adequately cooled in a three-fan system, without employing exotic solutions or even adding any fans.

As we know from the formula earlier in this chapter, processor power consumption is proportional to speed and is proportional to the square of the voltage it consumes. Even though processor voltages have been decreasing, speeds have been increasing at a much more rapid pace, such that power consumption is reaching all-time high levels beyond 120W. To combat this heat, heatsink manufacturers have increased the efficiency of processor heatsinks significantly over the past 10 to 15 years. Heatsinks are available today with thermal resistances on the order of 0.33° C/W or less. Unfortunately, conventional air-cooled heatsinks are fast approaching limits of the technology.

One cost-effective method of improving heatsink performance is to reduce the ambient temperature around the processor, which means lowering the temperature of air entering the heatsink. To ensure proper cooling for their boxed (retail) processors, Intel and AMD specify maximum temperature limits for the air that enters the heatsink fan assembly. If the air temperature entering the heatsink goes over that amount, the heatsink will not be able to adequately cool the processor. Because they must account for extreme circumstances, all modern systems and heatsinks are designed to operate properly if the external environmental ambient temperature in the room is 35° C (95° F). This means that, in general, PCs are designed to work in environments of up to that temperature. To operate in environments with higher temperatures than that, more specialized designs are required. [Table 21.2](#) shows the maximum heatsink air inlet temperatures allowed for various processors with factory-installed heatsinks.

Table 21.2. Maximum Heatsink Inlet Temperatures for Various Processors

Environmental Temp. Max. Heatsink Inlet Temp. Processor Type

35° C (95° F)	45° C (113° F)	AMD K6, Pentium I, II, III
35° C (95° F)	42° C (107.6° F)	AMD Athlon, XP, 64, 64 FX
35° C (95° F)	40° C (104° F)	Pentium 4 Willamette, Northwood
35° C (95° F)	38° C (100.4° F)	Pentium 4 Northwood 3GHz+, Prescott 2.4GHz+

As you can see, for a long time new processors continually made more demands on system cooling. With the recent trend on the part of Intel and AMD to increase speed through chip design rather than pure clock speed increases, this trend has plateaued to an extent. The most demanding processors today require that the internal chassis temperature remain at or below 38° C (100.4° F), even if the system is running in a room temperature of 35° C (95° F). The internal temperature rise, or pre-heating of air inside the system, is typically caused by heat from components such as motherboard chipsets, graphics cards, memory, voltage regulators, disk drives, and other heat-generating components (including the processor itself). Even with all these devices producing heat, the specifications for many newer processors require that the air temperature inside the chassis at the heatsink can rise only to 3° C (5.4° F) over ambient. This places extreme demands on the chassis cooling.

Conventional chassis are incapable of maintaining that low of a differential between the chassis interior and ambient temperatures. The only way to achieve that has been by adding an excessive amount of fans to the system, which unfortunately adds cost and significantly adds to the noise level. Many systems with multiple fans on the front, rear, and sides are still incapable of maintaining only 3° C (5.4° F) over ambient at the processor heatsink. Fortunately, a simple solution was derived that not only solves the problem, but also adds no fans and very little cost to a system. The best part is that this new design can be added to most existing chassis for under \$10 in parts and has an easy installation.

Both Intel and AMD have been releasing documents describing the thermal attributes of their processors and guides showing ideas for cooling systems and chassis designs that can adequately cool the system. Chassis that have been specifically designed to improve cooling for the processor by maintaining a temperature of 38° C or less at the processor heatsink inlet are often referred to as *thermally advantaged chassis*. Using a thermally advantaged chassis both allows the processor to remain cool even under extreme environmental conditions and helps reduce noise. Most modern processors and chassis incorporate cooling systems that can adjust the speeds of the fans. If the temperatures remain below specific limits, the fans run at lower speeds, thus reducing the noise level. If temperatures rise, so do fan speeds and noise. In general, thermally advantaged chassis enable fan speeds to remain lower, resulting in quieter operation.

To meet the thermally advantaged chassis requirements, the following specifications are recommended:

- Accepts an industry-standard ATX, MicroATX, or FlexATX motherboard
- Accepts an industry-standard ATX, SFX, or TFX power supply with integral exhaust fan
- Uses a removable side cover with an adjustable processor duct and adapter card vent
- Provides a primary chassis rear exhaust fan of 92mm or larger and an optional front-mounted 80mm fan (excluding any fans in the power supply)

Because a thermally advantaged chassis is much better at cooling for very little extra cost, I highly recommend you look for these features on the next system you buy or build.

Processor Duct

The latest advancement in chassis design is the addition of a duct or air guide directly over the processor. This is called a *processor duct* or *chassis air guide*, and it essentially enables the processor heatsink to draw air directly from outside the chassis, greatly improving the thermal performance of the processor heatsink and easily meeting the requirement for a 38° C or lower heatsink inlet temperature. The specifications for this duct, and for an additional vent in the side cover for adapter cards such as graphics boards, can be found in an official standard called the Chassis Air Guide design guide, which was initially published in May 2002 and revised in September 2003. This guide details the dimensions and locations of the processor duct, as well as other attributes of the design. [Figure 21.22](#) shows a typical tower chassis with the processor duct installed in the side cover.

Figure 21.22. Thermally advantaged chassis featuring a processor air duct and adapter card vent in the side cover.

The processor duct is essentially a tube positioned directly over the processor heatsink, allowing it to pull cool air from outside the chassis. When viewed from the side, the duct is usually covered by a grille or vent cover. [Figure 21.23](#) shows the processor duct and adapter card vents as viewed from the side.

Figure 21.23. Thermally advantaged chassis processor duct and adapter card vent as viewed from the side.

The processor duct is the most important part of the thermally advantaged chassis design, and the placement of the duct is critical to its performance. The duct must be centered over the processor heatsink, and it must be positioned such that the end of the duct is spaced 12mm-20mm from the top of the heatsink. This ensures that the processor heatsink ingests only cool air from outside the chassis and enables some air to spill over to cool other parts of the system. [Figure 21.24](#) shows the duct placement in relation to the top of the processor heatsink.

Figure 21.24. Processor air duct placement in relation to the processor heatsink.

Because chassis can vary in size, shape, and dimension, the Chassis Air Guide standard details the placement of the processor duct and adapter card vent in relation to an industry-standard ATX motherboard.

The effect of the processor duct is quite noticeable in system operation. In a study done by Intel, it tested a system running Windows XP with a 3GHz Pentium 4 processor, a D865PERL motherboard, a GeForce4 video card, DDR400 memory, a hard drive, a CD-ROM drive, a sound card, and both rear-and front-mounted 80mm fans. The system was running in a 25° C (77° F) room, and the test results were as follows:

	Without CPU Duct	With CPU Duct
--	------------------	---------------

CPU inlet temp.	35° C (95° F)	28° C (82.4° F)
-----------------	---------------	-----------------

CPU fan speed	4050rpm	2810rpm
---------------	---------	---------

Sound level	39.8 Db	29.9 Db
-------------	---------	---------

As you can see, adding the duct dropped the temperature of the processor by 7° C (12.6° F), even while allowing the heatsink fan speed to drop to the lowest setting. The result is a processor that runs cooler, a fan that lasts longer, and less noise. As you can see, even with dual chassis fans already in the system, the processor duct makes a huge difference.

By selecting a thermally advantaged chassis, you ensure that your processor remains cool under the most extreme environmental conditions, not to mention that you extend the life of the heatsink fan and cause your system to be much quieter overall.

Functional Chassis Mod: Adding a Processor Duct

Now that you know to look for a thermally advantaged chassis with a processor duct for your next system, what about the systems you already have? Fortunately, this is one modification that is extremely easy to perform to an existing system. Unlike purely cosmetic modifications, this mod benefits your system tremendously and is much more about function and performance than it is about looks.

After studying the Chassis Air Guide specifications, I thought this would be a perfect mod to perform to one of my existing systems. The benefits are obvious: A cooler processor is a happier processor, and the rest of the system is happier as well. If you had thoughts about overclocking, this modification will improve the cooling capability of your existing heatsink such that you won't need to replace it even in an overclocking situation.

After searching the local home improvement and hardware stores, I found the perfect solution for adding a processor duct to an existing system in the plumbing section! As I was looking over various fittings and parts to see what I could make work in the most efficient and least costly manner, I heard the inevitable "Can I help you?" from one of the store attendants. I thought to myself, "How am I going to answer? I mean, I can't really tell him I'm looking for parts to modify my computer! Ahh, what the heck," I thought. So, I said, "Okay, maybe you can help. I'm looking for parts that I can use to add a processor duct to my computer, which conforms to the official Chassis Air Guide 1.1 standard, thus making it a thermally advantaged chassis." "Um, never mind..." was all he could say in response, as he walked away shaking his head.

After checking everything out, I found that I could design and install the modification using only two parts as follows:

Item	P/N	Price
2" no-caulk shower drain (PVC)	30171	\$5.97
4" flexible downspout connector (rubber)	PDSC 43	\$2.99
Total		\$8.96

I purchased these parts at Menards; however, any decent home improvement or hardware store should have them. The parts are shown in [Figure 21.25](#).

Figure 21.25. 2" no-caulk shower drain (for processor duct) and a 4" rubber flexible downspout connector (for processor duct).

The duct is exceedingly simple; it merely consists of the two pieces mated. The rubber downspout connector slips over the threaded end of the PVC shower drain and can be adjusted or even trimmed to get the precise distance from the top of the CPU heatsink.

To install the duct, follow these directions:

1. Remove the chassis side cover. Place a layer of masking tape completely covering the outer skin of the side cover to protect the paint from scratches when you are cutting the hole.
2. Looking at the cover as it would be positioned on the chassis, make a mark directly over the center position of the processor heatsink.
3. Using a hole saw, jigsaw, or other tools, cut a 3.25" (82.5mm) hole in the side cover, using the mark you made as the center point. The hole does not have to be cosmetically perfect or precise because the flange on the PVC shower drain will cover about a quarter of an inch of material beyond the hole.
4. Take the PVC shower drain and pull off the stainless steel strainer (it snaps off); then remove and discard the internal locknut, locknut spinner, and no-caulk gasket.
5. Unscrew the outer locknut, remove the paper and rubber gaskets, and discard the paper gasket.
6. Slide the PVC drain into the hole in the side cover, with the flange on the outside and the threaded portion on the inside.
7. Slip the rubber gasket over the threaded portion, and then screw on the outer locknut and tighten it down.
8. Take the rubber flexible downspout connector and slide the narrow portion over the threads on the PVC shower drain.

9. Place the cover and duct assembly back on the system for a trial fitting, look through the open duct, and measure the distance between the end of the rubber downspout connector and the top of the processor (see [Figure 21.26](#)).

Figure 21.26. Peering through the duct to measure the clearance between the duct and processor heatsink.

10. Remove the side cover and duct assembly; then trim the rubber downspout connector with a knife or razor blade as necessary, so the distance from the end of the connector and the top of the CPU heatsink is between 12mm and 20mm (approx. 0.47"0.79"). You might need to refit the cover several times when measuring and trimming.
11. Finally, snap the stainless steel strainer into place on the duct, and reinstall the side cover and duct assembly on the system (see [Figure 21.27](#)).

Figure 21.27. Side cover with the duct being reinstalled on the chassis.

As you can see, the instructions are simple. The most difficult part is cutting the hole in the side cover. But even that isn't terribly hard, mainly because the flange of the drain covers an additional quarter of an inch of the cover, hiding the fact that the hole might be out of round or have rough edges.

[Figure 21.28](#) shows the finished product, complete with stainless steel strainer.

Figure 21.28. Processor duct and adapter card vent locations in relation to an ATX motherboard.

The system I used already had a vent for the adapter card area. Plus, it used a 92mm rear fan, so with the addition of the processor duct, it now fully meets the thermally advantaged chassis with Chassis Air Guide standards. Not only is it functional, but it actually looks pretty good, too. The stainless steel strainer adds an "industrial" look to the mod, adding a little form to the function.

Upon powering up the system with the duct in place, I immediately noticed that the processor was pulling air through the duct, allowing it to run noticeably cooler. Not bad for under \$9 and about 15 minutes to cut the hole!

Chapter 22. PC Diagnostics, Testing, and Maintenance

[PC Diagnostics](#)

[Diagnostics Software](#)

[The Hardware Boot Process](#)

[PC Maintenance Tools](#)

[Preventive Maintenance](#)

[Troubleshooting Tips and Techniques](#)

PC Diagnostics

No matter how well built your PC is and how well written its software, something is eventually going to go wrong, and you might not always have a support system available to resolve the problem. Diagnostic software can be vitally important to you anytime your computer malfunctions or you are in the process of upgrading a system component or especially building an entirely new system from scratch. This chapter examines the types of diagnostics software available, and particularly those utilities you might already own because they are included with common operating systems and hardware products.

You also might find that your system problems are caused by a hardware malfunction and that you must open the computer case to perform repairs. This chapter also examines the tools and testers used to upgrade and repair PCsboth the basic items every user should own and some of the more advanced devices.

Of course, the best way to deal with a problem is to prevent it from occurring in the first place. The preventive maintenance sections of this chapter describe the procedures you should perform on a regular basis to keep your system in good working order. This chapter describes several levels of diagnostic software that are either included with your system or available from your system manufacturer and third parties. This chapter describes how you can get the most from this software. It also details the various ROM BIOS audio codes and error codes and examines aftermarket diagnostics and public-domain diagnostic software.

Diagnostics Software

Several types of diagnostic software are available for PCs. Some diagnostic functions are integrated into the PC hardware or into peripheral devices, such as expansion cards, whereas others take the form of operating system utilities or separate software products. This software, some of which is included with the system when purchased, assists users in identifying many problems that can occur with a computer's components. In many cases, these programs can do most of the work in determining which PC component is defective or malfunctioning. The types of diagnostic software are as follows:

- *POST.* The power on self test operates whenever any PC is powered up (switched on). These routines are contained within the motherboard ROM as well as ROMs on expansion cards.
- *Manufacturer-supplied diagnostics software.* Many of the larger manufacturers especially high-end, name-brand manufacturers such as IBM, Hewlett-Packard, Dell, and others make special diagnostics software expressly designed for their systems. This manufacturer-specific software normally consists of a suite of tests that thoroughly examines the system. In some cases, these utilities are included with the system, or you can download these diagnostics from the manufacturer's online services at no charge; otherwise, you might have to purchase them. Many vendors include a limited version of one of the aftermarket packages that has been customized for use with their systems. In some older IBM and Compaq systems, the diagnostic software is installed on a special partition on the hard drive and can be accessed during startup. This was a convenient way for those system manufacturers to ensure that users always had diagnostics available.
- *Peripheral diagnostics software.* Many hardware devices ship with specialized diagnostics software designed to test their particular functions. Adaptec SCSI host adapters, for example, include diagnostic functions in the card's ROM BIOS that you can access with a keystroke (Ctrl+A) at boot time. Sound cards normally include a diagnostic program on a disk along with the drivers, which test and verify all the card's functions. Network adapters usually include a diagnostic specific to that adapter on a disk, also normally with the drivers. Other devices or adapters also might provide a diagnostic program or disk, usually included with the drivers for the device.
- *Operating system diagnostics software.* Operating systems, such as Windows 9x/Me and Windows NT/2000/XP, include a variety of diagnostic software utilities designed to identify and monitor the performance of various components in the computer.
- *Aftermarket diagnostics software.* A number of manufacturers make general-purpose diagnostics software for PCs. This type of software is often bundled with other system maintenance and repair utilities to form a general PC software toolkit.

The Power On Self Test

When IBM first began shipping the original PC in 1981, it included safety features that had never been seen in a personal computer. These features were the power on self test (POST) and parity-checked memory. Although parity-checked or even error correcting code (ECC) memory is no longer available in most low-end chipsets, every PC still executes a POST when you turn it on. The following sections provide more detail on the POST, a series of program routines buried in the motherboard ROM-BIOS chip that tests all the main system components at power-on time. This series of routines is partially responsible for the delay when you turn on your PC; the computer executes the POST before loading the operating system.

What Is Tested?

Whenever you start up your computer, it automatically performs a series of tests that checks the primary components in your system, such as the CPU, ROM, motherboard support circuitry, memory, and major peripherals such as the expansion chassis. These tests are brief and are designed to catch hard (not intermittent) errors. The POST procedures are not very thorough compared with available disk-based diagnostics. The POST process provides error or warning messages whenever it encounters a faulty component.

Although the diagnostics performed by the system POST are not very thorough, they are the first line of defense, especially when it comes to detecting severe motherboard problems. If the POST encounters a problem severe enough to keep the system from operating properly, it halts the system boot process and generates an error message that often identifies the cause of the problem. These POST-detected problems are sometimes called *fatal errors* because they prevent the system from booting.

How Errors Are Displayed

The POST tests normally provide three types of output messages: audio codes, onscreen text messages, and hexadecimal numeric codes that are sent to an I/O port address.

POST errors can be displayed in the following three ways:

- *Beep codes*. Heard through the speaker attached to the motherboard.
- *POST checkpoint codes*. Hexadecimal checkpoint codes sent to an I/O port address. A special card plugged into either an ISA or a PCI card slot is required to view these codes.
- *Onscreen messages*. Error messages displayed onscreen after the video adapter is initialized.

BIOS POST Beep Codes

Beep codes are used for fatal errors only, which are errors that occur so early in the process that the video card and other devices are not yet functional. Because no display is available, these codes take the form of a series of beeps that identify the faulty component. When your computer is functioning normally, you should hear one short beep when the system starts up at the completion of the POST, although some systems (such as Compaq's) beep twice at the end of a normal POST. If a problem is detected, a different number of beeps sounds, sometimes in a combination of short and long tones.

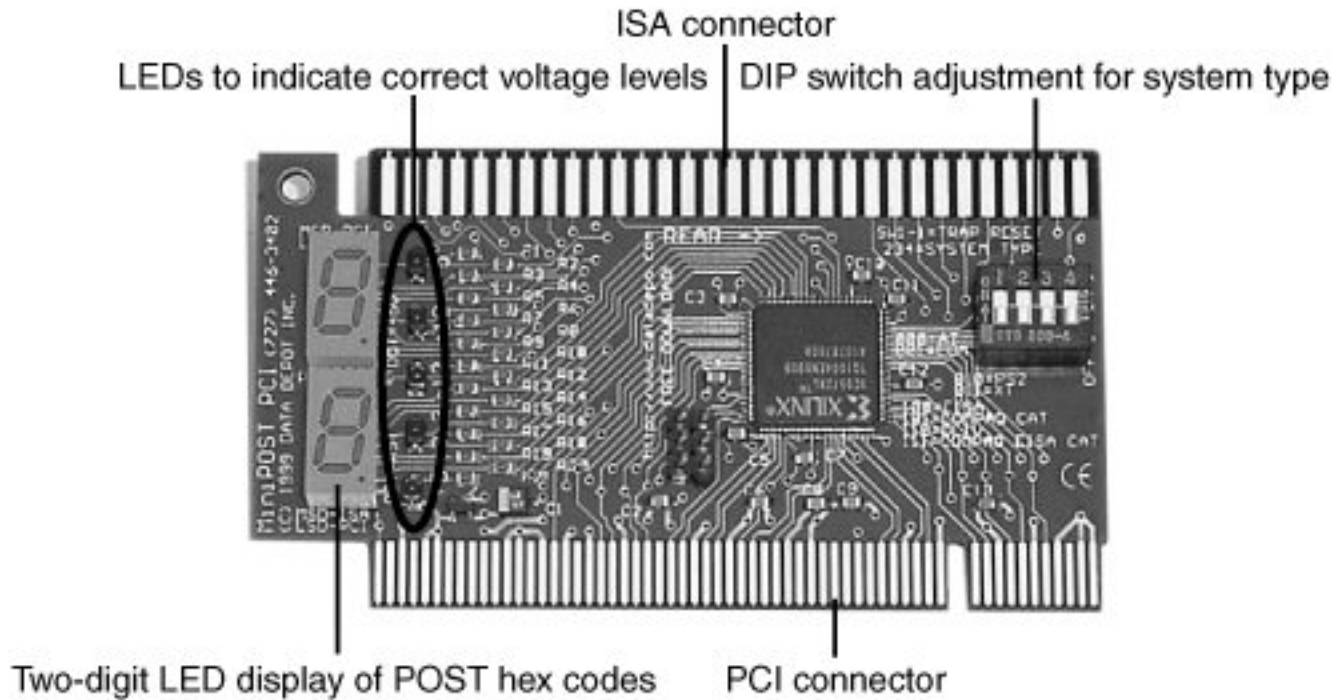

BIOS POST Checkpoint Codes

POST checkpoint codes are hexadecimal numeric codes written by POST routines to I/O port address 80h as each major step is begun. These are often simply called *POST codes*. These POST codes can be read by only a special adapter card plugged into one of the system slots. These cards originally were designed for system manufacturers to use for burn-in testing of the motherboard. Several companies make these cards available to technicians. Micro 2000, JDR Microdevices, Data Depot, Ultra-X, and Trinitech (search for PC Analyzer) are just a few manufacturers that market these POST cards. See the vendor list on the accompanying disc for more information about these manufacturers.

POST checkpoint codes can be used to track the system's progress through the boot process from power-on right up to the point at which the bootstrap loader runs (when the operating system load begins). When you plug a POST code reader card into a slot, during the POST you will see two-digit hexadecimal numbers flash on the card's display. If the system stops unexpectedly or hangs, you can identify the test that was in progress during the hang from the two-digit code. This step usually helps to identify the malfunctioning component.

Originally, most POST reader cards plugged into the 8-bit connector that is a part of the ISA or EISA bus. Some older PCI-based systems do still have ISA connectors that can use these cards. However, the motherboards found in most newer PCs have no ISA slots at all, so obviously an ISA POST card won't work. Fortunately, the companies that make POST cards more often than not make PCI versions. Micro 2000 has a card called the Post-Probe, which has both ISA and PCI connectors on the same board. PC Certify has a similar card called the PCISA FlipPOST (see [Figure 22.1](#)).

Figure 22.1. The PC Certify PCISA FlipPOST diagnostics card works with both PCI- and ISA-based systems, and it also tests motherboard voltage levels.

Although rare at this point, if you maintain older Compaq or EISA-based systems from any vendor, these systems might use an I/O port address other than port 80. Simpler POST cards monitor only port 80, but more sophisticated cards (such as the PCISA FlipPOST shown in [Figure 22.1](#)) have DIP switches or jumper blocks to configure the card to monitor the different I/O port addresses these systems used.

Note

Listings for additional POST checkpoint codes can be found in the Technical Reference section of the accompanying DVD. Also, see [Chapter 5](#), "BIOS," to learn more about working with your BIOS. Remember to consult your motherboard documentation for codes specific to your BIOS version. Also, the documentation included with the various POST cards covers most older as well as newer BIOS versions.

BIOS POST Onscreen Messages

Onscreen messages are brief messages that attempt to indicate a specific failure. These messages can be displayed only after the point at which the video adapter card and display have been initialized.

These different types of error messages are BIOS dependent and vary among BIOS manufacturers, and even in some cases among different BIOSs from the same manufacturer. The following sections list the codes used by the most popular ROM BIOS versions (AMI, Award, Phoenix, and IBM BIOS), but you should consult your motherboard or ROM BIOS manufacturer for the codes specific to your board and BIOS.

Most POST code cards come with documentation listing the POST checkpoint codes for various BIOS versions. If your BIOS is different from what I have listed here, consult the documentation for your BIOS or the information that came with your particular POST card.

Note

I've also included additional BIOS error messages in the Technical Reference section on the disc included with this book.

AMI BIOS POST Error Codes

Table 22.1. AMI BIOS POST Beep Codes

Beeps	Error Description	Action
1	Memory Refresh Error	Clean the memory contacts and reseat the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
2	Memory Parity Error	Clean the memory contacts and reseat the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
3	Base 64KB Memory Error	Clean the memory contacts and reseat the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
4	Timer Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
5	Processor Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Make sure the processor and heatsink are installed properly; remove and reseat them. Replace the processor. Replace the motherboard.

6	8042 Gate A20 Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the keyboard, motherboard, and processor.
7	Processor Exception Interrupt Error	Make sure the processor and heatsink are installed properly; remove and reseal them. Replace the processor. Replace the motherboard.
8	Display Memory Read/Write Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
9	ROM Checksum Error	Try reseating the motherboard ROM chip. Try reflashing the motherboard ROM. Replace the motherboard.
10	CMOS Shutdown Register Read/Write Error	Replace the CMOS battery. Replace the motherboard.
11	Cache Memory Bad	Make sure cache settings in BIOS Setup are properly configured. Replace the processor. Replace the motherboard.
1 long, 3 short	Conventional/Extended Memory Error	Clean the memory contacts and reseal the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
1 long, 8 short	Display/Retrace Error	Check the video card for proper installation. Try replacing the video card memory. Replace the video card. Replace the motherboard.

AMI BIOS codes used by permission of American Megatrends, Inc.

If you have a POST card, you can find the AMI BIOS POST checkpoint codes in the Technical Reference section of the disc packaged with this book.

Award BIOS and Phoenix FirstBIOS POST Error Codes

Currently, only one standard beep code exists in the Award BIOS (also known as the Phoenix FirstBIOS). A single long beep followed by two short beeps indicates that a video error has occurred and that the BIOS cannot initialize the video screen to display any additional information. If multiple or continuous beeps occur with an Award BIOS, this usually indicates problems with the power supply or memory.

Table 22.2. AwardBIOS/Phoenix FirstBIOS POST Beep Codes

Beeps	Error Description	Action
1 long, 2 short	Video Card Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
1 long, 3 short	Video Card Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
Continuous beeps	Memory Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.

If you have a POST card, you can find the AwardBIOS and Phoenix FirstBIOS POST checkpoint codes in the Technical Reference section of the disc packaged with this book.

Table 22.3. AwardBIOS POST Onscreen Error Messages

Message	Description
BIOS ROM checksum error - System halted	The checksum of the BIOS code in the BIOS chip is incorrect, indicating the BIOS code might have become corrupt. Contact your system dealer to replace the BIOS.
CMOS battery failed	The CMOS battery is no longer functional. Contact your system dealer for a replacement battery.
CMOS checksum error - Defaults loaded	Checksum of CMOS is incorrect, so the system loads the default equipment configuration. A checksum error can indicate that CMOS has become corrupt. This error might have been caused by a weak battery. Check the battery and replace if necessary.
CPU at <i>nnnn</i>	Displays the running speed of the CPU.
Display switch is set incorrectly	The display switch on the motherboard can be set to either monochrome or color. This message indicates the switch is set to a different setting than indicated in Setup. Determine which setting is correct, and then either turn off the system and change the jumper or enter Setup and change the VIDEO selection.
Press ESC to skip memory test	The user can press Esc to skip the full memory test.

Floppy disk(s) fail

Can't find or initialize the floppy drive controller or the drive. Make sure the controller is installed correctly. If no floppy drives are installed, be sure the Diskette Drive selection in Setup is set to **NONE** or **AUTO**.

HARD DISK initializing. Please wait a moment

Some hard drives require extra time to initialize.

HARD DISK INSTALL FAILURE

Can't find or initialize the hard drive controller or the drive. Make sure the controller is installed correctly. If no hard drives are installed, be sure the Hard Drive selection in Setup is set to **NONE**.

Hard disk(s) diagnosis fail

The system might run specific disk diagnostic routines. This message appears if one or more hard disks return an error when the diagnostics run.

Keyboard error or no keyboard present

Can't initialize the keyboard. Make sure the keyboard is attached correctly and no keys are pressed during POST. To purposely configure the system without a keyboard, set the error halt condition in Setup to **HALT ON ALL, BUT KEYBOARD**. The BIOS then ignores the missing keyboard during POST.

Keyboard is locked out - Unlock the key

This message usually indicates that one or more keys have been pressed during the keyboard tests. Be sure no objects are resting on the keyboard.

Memory Test:

This message displays during a full memory test, counting down the memory areas being tested.

Memory test fail

If POST detects an error during memory testing, additional information appears giving specifics about the type and location of the memory error.

Override enabled - Defaults loaded

If the system can't boot using the current CMOS configuration, the BIOS can override the current configuration with a set of BIOS defaults designed for the most stable, minimal-performance system operations.

Press TAB to show POST screen

System OEMs might replace Phoenix Technologies' AwardBIOS POST display with their own proprietary displays. Including this message in the OEM display permits the operator to switch between the OEM display and the default POST display.

Primary master hard disk fail

POST detects an error in the primary master IDE hard drive.

Primary slave hard disk fail

POST detects an error in the secondary master IDE hard drive.

Resuming from disk, Press TAB to show POST screen

Phoenix Technologies offers a save-to-disk feature for notebook computers. This message might appear when the operator restarts the system after a save-to-disk shutdown.

Secondary master hard disk fail	POST detects an error in the primary slave IDE hard drive.
Secondary slave	POST detects an error in the secondary slave IDE hard hard disk fail drive.

PhoenixBIOS POST Error Codes

The following codes are for the PhoenixBIOS, version 4.

Table 22.4. PhoenixBIOS 5.x and Earlier POST Beep Codes

Beeps	Error Description	Action
1-2	Video Card Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
1-3	CMOS RAM Read/Write Error	Replace the CMOS battery. Replace the motherboard.
1-1-4	ROM Checksum Error	Try reseating the motherboard ROM chip. Try reflashing the motherboard ROM. Replace the motherboard.
1-2-1	Timer Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
1-2-2	DMA Initialization Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
1-2-3	DMA Page Register Read/Write Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
1-3-1	RAM Refresh Verification Error	Clean the memory contacts, and reseat the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
1-3-3	First 64KB RAM Multibit Data Line Error	Clean the memory contacts, and reseat the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.

1-3-4	First 64KB RAM Odd/Even Logic Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
1-4-1	First 64KB RAM Address Line Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory, power supply, and motherboard.
1-4-2	First 64KB RAM Parity Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
2-x-x ^[*]	First 64KB RAM Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
3-1-1	Slave DMA Register Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
3-1-2	Master DMA Register Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
3-1-3	Master Interrupt Mask Register Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
3-1-4	Slave Interrupt Mask Register Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
3-2-4	Keyboard Controller Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the keyboard. Replace the motherboard. Replace the processor.
3-3-4	Screen Initialization Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
3-4-1	Screen Retrace Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
3-4-2	Video ROM Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.
4-2-1	Timer Interrupt Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.

4-2-2	Shutdown Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the keyboard. Replace the motherboard. Replace the processor.
4-2-3	Gate A20 Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the keyboard. Replace the motherboard. Replace the processor.
4-2-4	Unexpected Interrupt In Protected Mode	Check for a bad expansion card. Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
4-3-1	RAM Address Error >FFFh	Clean the memory contacts, reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
4-3-3	Interval Timer Channel 2 Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
4-3-4	Real Time Clock Error	Replace the CMOS battery. Replace the motherboard.
4-4-1	Serial Port Error	Reset the port configuration in BIOS Setup. Disable the port.
4-4-2	Parallel Port Error	Reset the port configuration in BIOS Setup. Disable the port.
4-4-3	Math Coprocessor Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Make sure the processor and heatsink are installed properly; remove and reseal them. Replace the processor. Replace the motherboard.
Low 1-1-2	System Board Select Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Make sure the processor and heatsink are installed properly; remove and reseal them. Replace the processor. Replace the motherboard.
Low 1-1-3	Extended CMOS RAM Error	Replace the CMOS battery. Replace the motherboard.

[*] Second and third codes can be 14 beeps each, indicating different failed bits within the first 64KB of RAM.

Table 22.5. PhoenixBIOS 6.x and Later POST Beep Codes

Beeps	Error Description	Description/Action
1-2-2-3	BIOS ROM Checksum Error	Try reseating the motherboard ROM chip. Try reflashing the motherboard ROM. Replace the motherboard.
1-3-1-1	DRAM Refresh Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
1-3-1-3	8742 Keyboard Controller Error	Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the keyboard. Replace the motherboard. Replace the processor.
1-3-4-1	Memory Address Line Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
1-3-4-3	Memory Low Byte Data Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
1-4-1-1	Memory High Byte Data Error	Clean the memory contacts, and reseal the modules. Remove all modules except the first bank. Replace the memory. Replace the power supply. Replace the motherboard.
2-1-2-3	ROM Copyright Error	Try reseating the motherboard ROM chip. Try reflashing the motherboard ROM. Replace the motherboard.
2-2-3-1	Unexpected Interrupts	Check for a bad expansion card. Check for proper motherboard installation, loose screws, foreign objects causing shorts, and over-tightened screws. Replace the motherboard.
1-2	Video Card Error	Check the video card for proper installation. Try replacing the video card memory, and replace the video card. Replace the motherboard.

If you are using a POST card, you can find the PhoenixBIOS POST codes in the Technical Reference section of the disc packaged with this book.

IBM BIOS POST Error Codes

Table 22.6. IBM BIOS Beep Codes

Audio Code	Description
1 short beep	Normal POSTsystem okay

2 short beeps	POST errorview code on screen
No beep	Power supply, motherboard
Continuous beep	Power supply, motherboard
Repeating short beeps	Power supply, motherboard
1 long, 1 short beep	Motherboard
1 long, 2 short beeps	Video card (MDA/CGA)
1 long, 3 short beeps	Video card (EGA/VGA)
3 long beeps	3270 keyboard card

IBM BIOS beep and alphanumeric error codes used by permission of IBM.

Table 22.7. IBM BIOS POST/Diagnostics Display Error Codes

Code	Description
1xx	System board errors
2xx	Memory (RAM) errors
3xx	Keyboard errors
4xx	Monochrome Display Adapter (MDA) errors
4xx	PS/2 system board parallel port errors
5xx	Color Graphics Adapter (CGA) errors
6xx	Floppy drive/controller errors
7xx	Math Coprocessor errors
9xx	Parallel printer adapter errors
10xx	Alternate parallel printer adapter errors
11xx	Primary Async Communications (Serial COM1:) errors
12xx	Alternate Async Communications (Serial COM2:, COM3:, and COM4:) errors
13xx	Game control adapter errors
14xx	Matrix printer errors
15xx	Synchronous Data Link Control (SDLC) Communications adapter errors
16xx	Display Station Emulation Adapter (DSEA) errors (5520, 525x)
17xx	ST-506/412 fixed disk and controller errors

18xx	I/O expansion unit errors
19xx	3270 PC attachment card errors
20xx	Binary Synchronous Communications (BSC) adapter errors
21xx	Alternate Binary Synchronous Communications (BSC) adapter errors
22xx	Cluster adapter errors
23xx	Plasma monitor adapter errors
24xx	Enhanced graphics adapter (EGA) or video graphics array (VGA) errors
25xx	Alternate Enhanced Graphics Adapter (EGA) errors
26xx	XT or AT/370 370-M (memory) and 370-P (processor) adapter errors
27xx	XT or AT/370 3277-EM (emulation) adapter errors
28xx	3278/79 emulation adapter or 3270 connection adapter errors
29xx	Color/graphics printer errors
30xx	Primary PC network adapter errors
31xx	Secondary PC network adapter errors
32xx	3270 PC or AT display and programmed symbols adapter errors
33xx	Compact printer errors
35xx	Enhanced display station emulation adapter (EDSEA) errors
36xx	General-purpose interface bus (GPIB) adapter errors
37xx	System board SCSI controller errors
38xx	Data acquisition adapter errors
39xx	Professional graphics adapter (PGA) errors
44xx	5278 display attachment unit and 5279 display errors
45xx	IEEE interface adapter (IEEE 488) errors
46xx	A real-time interface coprocessor (ARTIC) multiport/2 adapter errors
48xx	Internal modem errors
49xx	Alternate internal modem errors
50xx	PC-convertible LCD errors
51xx	PC-convertible portable printer errors
56xx	Financial communication system errors
70xx	PhoenixBIOS/chipset unique error codes
71xx	Voice communications adapter (VCA) errors

73xx	3 1/2" external disk drive errors
74xx	IBM PS/2 display adapter (VGA Card) errors
74xx	8514/A display adapter errors
76xx	4216 PagePrinter adapter errors
84xx	PS/2 speech adapter errors
85xx	2MB XMA memory adapter or XMA adapter/A errors
86xx	PS/2 pointing device (mouse) errors
89xx	Musical Instrument Digital Interface (MIDI) adapter errors
91xx	IBM 3363 write-once read multiple (WORM) optical drive/adapter errors
96xx	SCSI adapter with cache (32-bit) errors
100xx	Multiprotocol adapter/A errors
101xx	300/1200bps internal modem/A errors
104xx	ESDI or MCA IDE fixed disk or adapter errors
107xx	5 1/4" external disk drive or adapter errors
112xx	SCSI adapter (16-bit without cache) errors
113xx	System board SCSI adapter (16-bit) errors
129xx	Processor complex (CPU board) errors
149xx	P70/P75 plasma display and adapter errors
152xx	XGA display adapter/A errors
164xx	120MB internal tape drive errors
165xx	6157 streaming tape drive or tape attachment adapter errors
166xx	Primary Token-Ring network adapter errors
167xx	Alternate Token-Ring network adapter errors
180xx	PS/2 wizard adapter errors
185xx	DBCS Japanese display adapter/A errors
194xx	80286 memory-expansion option memory-module errors
200xx	Image adapter/A errors
208xx	Unknown SCSI device errors
209xx	SCSI removable disk errors
210xx	SCSI fixed disk errors
211xx	SCSI tape drive errors

212xx	SCSI printer errors
213xx	SCSI processor errors
214xx	SCSI write-once read multiple (WORM) drive errors
215xx	SCSI CD-ROM drive errors
216xx	SCSI scanner errors
217xx	SCSI magneto optical drive errors
218xx	SCSI jukebox changer errors
219xx	SCSI communications errors
243xxxx	XGA-2 adapter/A errors
1998xxxx	Dynamic configuration select (DCS) information codes
199900xx	Initial microcode load (IML) error
199903xx	No bootable device, initial program load (IPL) errors
199904xx	IML-to-system mismatch
199906xx	IML (boot) errors

IBM BIOS beep and alphanumeric error codes used by permission of IBM.

POST Memory Count

On some PCs, the POST also displays the results of its system memory test on the monitor. The last number displayed is the amount of memory that tested successfully. For example, a system might display the following message:

32768 KB OK

The number displayed by the memory test should agree with the total amount of memory installed on the system motherboard. Some older systems display a slightly lower total because they deduct part or all of the 384KB of UMA (upper memory area) from the count. On old systems that use expanded memory cards, the memory on the card is not tested by the POST and does not count in the numbers reported. Also, this memory test is performed before any system software loads, so many memory managers or device drivers you might have installed do not affect the results of the test. If the POST memory test stops short of the expected total, the number displayed can indicate how far into the system memory array a memory error lies. This number can help you identify the exact module that is at fault and can be a valuable troubleshooting aid in itself.

Peripheral Diagnostics

Many types of diagnostic software are used with specific hardware products. This software can be integrated into the hardware, included with the hardware purchase, or sold as a separate product. The following sections examine several types of hardware-specific diagnostics.

SCSI Diagnostics

Unlike the IDE drive support that is built into the system BIOS of virtually every PC, SCSI is an add-on technology, and most SCSI host adapters contain their own BIOS that enables you to boot the system from a SCSI hard drive. In some cases, the SCSI BIOS also contains configuration software for the adapter's various features, and diagnostics software as well.

The most popular manufacturer of SCSI host adapters is Adaptec, and most of its host adapters contain these features. An Adaptec SCSI adapter normally includes a BIOS that can be enabled or disabled. When the BIOS is activated, you see a message on the monitor as the system boots, identifying the model of the adapter and the revision number of the BIOS. The message also instructs you to press Ctrl+A to access what Adaptec calls its SCSISelect utility.

The SCSISelect utility identifies the Adaptec host adapters installed in the system and, if more than one exists, enables you to choose the adapter you want to work with by selecting its port address. After you do this, you are presented with a menu of the functions built into the adapter's BIOS. Every adapter BIOS contains a configuration program and a SCSI Disk Utilities feature that scans the SCSI bus, identifying the devices connected to it. For each hard disk drive connected to the bus, you can perform a low-level disk format or scan the disk for defects, remapping any bad blocks that are found.

For SCSI adapters that use direct memory access (DMA), a Host Adapter Diagnostics feature is also available, which tests the communication between the adapter and the main system memory array by performing a series of DMA transfers. If this test fails, you are instructed how to configure the adapter to use a lower DMA transfer rate.

Network Interface Diagnostics

As with SCSI adapters, many network interface adapters are equipped with their own diagnostics, designed to test their own specialized functions. Depending on the network adapter, these tests might require you to boot with a DOS disk, or they might function within Windows.

The DIAG program included with all Linksys network interface cards, for example, performs the following internal tests on the Linksys EtherFast 10/100 Ethernet adapter:

- Configuration test
- I/O test
- ID test
- Internal Loopback test
- Link Status test
- Interrupt test
- Network Function test

The Network Function test sequence requires that you have another node installed on the same network with a Linksys adapter. By running the Diag software on both computers, you can configure one adapter to send data and the other to be the receiver. The sender transmits test messages to the receiver, which echoes the same messages back again. If the adapters and network are functioning properly, the messages should return to the sending system in exactly the same form as they were transmitted.

Other network adapters have similar testing capabilities, although the names of the tests might not be exactly the same.

If you do not have the driver or diagnostics files for your network adapter, you can normally download them free of charge from the manufacturers' respective websites.

General-Purpose Diagnostics Programs

A large number of professional third-party diagnostics programs are available for PC systems. These are commercial programs that are used by technicians to perform testing of new systems (often called burn-in testing) or testing of existing systems either in the shop or in the field.

Most of the commercial PC diagnostics can test all your PC's key components. In addition, specific programs are available to test memory, floppy drives, hard disks, video adapters, and most other areas of the system. Some of the programs I recommend most highly include

- *AMIDdiag Suite*. See www.ami.com for more information.
- *MicroScope*. See www.micro2000.com for more information.

Tip

Before trying a commercial diagnostic program to solve your problem, look in your operating system. Most operating systems today provide at least some of the diagnostic functions that diagnostic programs do. You might be able to save some time and money.

Unfortunately, no clear leader exists in the area of diagnostic software. Each program has unique advantages, and as a result, no program is universally better than another. When deciding which diagnostic programs to include in your arsenal, look for the features you need.

One of the most popular is AMIDdiag from AMI. This program runs on virtually any PC and tests most of the hardware in the system. AMIDdiag is available in a native Windows version that also supports third-party diagnostics modules or in a DOS version that can be used to test hardware, regardless of the operating system, by using a DOS boot disk to start the system.

Note

The disc included with this book contains a breakdown of some of the PC diagnostics software available today. See the Technical Reference section of the disc.

Operating System Diagnostics

In many cases, it might not be necessary to purchase third-party diagnostic software because your operating system has all the diagnostic tools you need. Windows 9x/Me and NT/2000/XP include a large selection of programs that enable you to view, monitor, and troubleshoot the hardware in your system.

Windows XP has numerous tools, utilities, and error-reporting features that can be useful in helping you determine the cause of problems. The most serious problems can be caused by corrupt files or buggy

software on the system, as well as defective or incorrectly configured hardware, and will often result in a STOP or "blue-screen" error, causing Windows to enter a special debugging mode. When this happens, Windows XP is normally configured to save a dump of the error in a memory dump file, which can be useful if it is a software bug you are going to report to Microsoft. Still, it is always a good idea to write down the error for future reference.

The Hardware Boot Process

The term *boot* comes from the word bootstrap and describes the method by which the PC becomes operational. Just as you pull on a large boot by the small strap attached to the back, a PC loads a large operating system by first loading a small program that can then pull the operating system into memory. The chain of events begins with the application of power and finally results in a fully functional computer system with software loaded and running. Each event is triggered by the event before it and initiates the event after it.

Tracing the system boot process might help you find the location of a problem if you examine the error messages the system displays when the problem occurs. If you see an error message that is displayed by only a particular program, you can be sure the program in question was at least loaded and partially running. Combine this information with the knowledge of the boot sequence, and you can at least tell how far the system's startup procedure had progressed before the problem occurred. You usually should look at whichever files or disk areas were being accessed during the failure in the boot process. Error messages displayed during the boot process and those displayed during normal system operation can be hard to decipher. However, the first step in decoding an error message is knowing where the message came from which program actually generated or displayed it. The following programs are capable of displaying error messages during the boot process:

OS Independent:

- Motherboard ROM BIOS
- Adapter card ROM BIOS extensions
- Master (partition) boot record (MBR)
- Volume boot record (VBR)

OS Dependent

- System files
- Device drivers (loaded through **CONFIG.SYS** or the Win Registry **SYSTEM.DAT**)
- Programs run by **AUTOEXEC.BAT**, the Windows Startup group, and the Registry

The first portion of the startup sequence is *operating system independent*, which means these steps are the same for all PCs no matter which operating system is installed. The latter portion of the boot sequence is *operating system dependent*, which means those steps can vary depending on which operating system is installed or being loaded. The following sections examine both the operating-system-independent startup sequence and the operating-system-dependent startup process for various operating systems. These sections provide a detailed account of many of the error messages that might occur during the boot process.

The Boot Process: Operating System Independent

If you have a problem with your system during startup and can determine where in this sequence of events your system has stalled, you know which events have occurred and probably can eliminate each of them as a cause of the problem. The following steps occur in a typical system startup regardless of which operating system you are loading:

1. You switch on electrical power to the system.
2. The power supply performs a self-test (known as the POST). When all voltages and current levels are acceptable, the supply indicates that the power is stable and sends the Power_Good signal to the motherboard. The time from switch-on to Power_Good is normally between .1 and .5 seconds.
3. The microprocessor timer chip receives the Power_Good signal, which causes it to stop generating a reset signal to the microprocessor.

◀◀ See "[The Power_Good Signal](#)," p. [1146](#).

4. The microprocessor begins executing the ROM BIOS code, starting at memory address FFFF:0000. Because this location is only 16 bytes from the very end of the available ROM space, it contains a JMP (jump) instruction to the actual ROM BIOS starting address.

◀◀ See "[Motherboard BIOS](#)," p. [416](#).

5. The ROM BIOS performs a test of the central hardware to verify basic system functionality. Any errors that occur are indicated by audio "beep" codes because the video system has not yet been initialized. If the BIOS is Plug and Play (PnP), the following steps are executed; if not, skip to step 10.
6. The Plug and Play BIOS checks nonvolatile random access memory (RAM) for input/output (I/O) port addresses, interrupt request lines (IRQs), direct memory access (DMA) channels, and other settings necessary to configure PnP devices on the computer.
7. All Plug and Play devices found by the Plug and Play BIOS are disabled to eliminate potential conflicts.
8. A map of used and unused resources is created.
9. The Plug and Play devices are configured and reenabled, one at a time. If your computer does not have a Plug and Play BIOS, PnP devices are initialized using their default settings. These devices can be reconfigured dynamically when Windows starts. At that point, Windows queries the Plug and Play BIOS for device information and then queries each Plug and Play device for its configuration.
10. The BIOS performs a video ROM scan of memory locations C000:0000C780:0000 looking for video adapter ROM BIOS programs contained on a video adapter found either on a card plugged into a slot or integrated into the motherboard. If the scan locates a video ROM BIOS, it is tested by a checksum procedure. If the video BIOS passes the checksum test, the ROM is executed; then the video ROM code initializes the video adapter and a cursor appears onscreen. If the checksum test fails, the following message appears:

C000 ROM Error

11. If the BIOS finds no video adapter ROM, it uses the motherboard ROM video drivers to initialize the video display hardware, and a cursor appears onscreen.

12. The motherboard ROM BIOS scans memory locations C800:0000DF80:0000 in 2KB increments for any other ROMs located on any other adapter cards (such as SCSI adapters). If any ROMs are found, they are checksum-tested and executed. These adapter ROMs can alter existing BIOS routines and establish new ones.
13. Failure of a checksum test for any of these ROM modules causes this message to appear:

XXXX ROM Error

where the address XXXX indicates the segment address of the failed ROM module.

14. The ROM BIOS checks the word value at memory location 0000:0472 to see whether this start is a cold start or a warm start. A word value of 1234h in this location is a flag that indicates a warm start, which causes the BIOS to skip the memory test portion of the POST. Any other word value in this location indicates a cold start, and the BIOS performs the full POST procedure. Some system BIOSs let you control various aspects of the POST procedure, making it possible to skip the memory test, for example, which can be lengthy on a system with a lot of RAM.
15. If this is a cold start, the full POST executes; if this is a warm start, a mini-POST executes, minus the RAM test. Any errors found during the POST are reported by a combination of audio and displayed error messages. Successful completion of the POST is indicated by a single beep (with the exception of some Compaq computers, which beep twice).
16. The ROM BIOS searches for a boot record at cylinder 0, head 0, sector 1 (the very first sector) on the default boot drive. At one time, the default boot drive was always the first floppy disk, or A: drive. However, the BIOSs on today's systems often enable you to select the default boot device and the order in which the BIOS will look for other devices to boot from if necessary, using a floppy disk, hard disk, or even a CD-ROM drive in any order you choose. This sector is loaded into memory at 0000:7C00 and tested.

If a disk is in the drive but the sector can't be read, or if no disk is present, the BIOS continues with step 19.

Booting from CD-ROM or Floppy

If you do want to boot from a CD-ROM, be sure the CD-ROM drive is listed before the hard disk in the boot devices menu in your BIOS setup. To ensure that you can boot from an emergency CD or floppy disk, I recommend setting the CD-ROM as the first and the floppy drive as the second boot device. A hard disk containing your operating system should be the third device in the boot device list. This enables you to always be ready for an emergency. So long as you do not start up the system with a floppy or bootable CD loaded, the BIOS bypasses both the CD and floppy disk drives and boots from the hard drive.

Note that not all operating system CDs are bootable. Windows 95 CDs are not bootable; however, with Windows 98/Me, Microsoft made the operating system CD bootable, but only for OEM (original equipment manufacturer) versions. This does not extend to retail versions of these Windows CDs. Windows NT 4.0 and later, including Windows 2000 and XP, are shipped on bootable CDs, including all OEM, retail, and upgrade versions. Refer to [Chapter 11](#), "Optical Storage," for information on how to make a bootable CD.

-
17. If you are booting from a floppy disk and the first byte of the volume boot record is less than 06h, or if the first byte is greater than or equal to 06h and the first nine words contain the same data pattern, this error message appears and the system stops: **602-Diskette Boot Record Error**
 18. If the volume boot record can't find or load the system files, or if a problem was encountered loading them, one of the following messages appears:

Non-System disk or disk error
Replace and strike any key when ready

Non-System disk or disk error
Replace and press any key when ready

Invalid system disk_
Replace the disk, and then press any key

Disk Boot failure

Disk I/O Error

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

19. If no boot record can be read from drive A: (such as when no disk is in the drive), the BIOS then looks for a master boot record (MBR) at cylinder 0, head 0, sector 1 (the very first sector) of the first hard disk. If this sector is found, it is loaded into memory address 0000:7C00 and tested for a signature.
20. If the last two (signature) bytes of the MBR are not equal to 55AAh, software interrupt 18h (Int 18h) is invoked on most systems. This causes the BIOS to display an error message that can vary for different BIOS manufacturers, but which is often similar to one of the following messages, depending on which BIOS you have:

IBM BIOS:

The IBM Personal Computer Basic_
Version C1.10 Copyright IBM Corp 1981
62940 Bytes free_
Ok_

Most IBM computers since 1987 display a strange character graphic depicting the front of a floppy drive, a 3 1/2" disk, and arrows prompting you to insert a disk in the drive and press the F1 key to proceed.

AMI BIOS:

NO ROM BASIC - SYSTEM HALTED

Compaq BIOS:

Non-System disk or disk error
replace and strike any key when ready

AwardBIOS:

DISK BOOT FAILURE, INSERT SYSTEM DISK AND PRESS ENTER

PhoenixBIOS:

No boot device available -
strike F1 to retry boot, F2 for setup utility

or

No boot sector on fixed disk -
strike F1 to retry boot, F2 for setup utility

Although the messages vary from BIOS to BIOS, the cause for each relates to specific bytes in the MBR, which is the first sector of a hard disk at the physical location cylinder 0, head 0, sector 1.

The problem involves a disk that either has never been partitioned or has had the Master Boot Sector corrupted. During the boot process, the BIOS checks the last two bytes in the MBR (first sector of the drive) for a signature value of 55AAh. If the last two bytes are not 55AAh, an Interrupt 18h is invoked, which calls the subroutine that displays one of the error messages just shown, which basically instructs the user to insert a bootable floppy to proceed.

The MBR (including the signature bytes) is written to the hard disk by the FDISK, Disk Management, or DISKPART programs. Immediately after a hard disk is low-level formatted, all the sectors are initialized with a pattern of bytes, and the first sector does not contain the 55AAh signature. In other words, these ROM error messages are exactly what you see if you attempt to boot from a hard disk that has been freshly low-level formatted but has not yet been partitioned or if the MBR has been corrupted such that the signature bytes were overwritten.

21. The MBR searches its built-in partition table entries for a boot indicator byte marking an active partition entry.
22. If none of the partitions are marked active (bootable), the BIOS invokes software interrupt 18h, which displays an error message (refer to step 20).

23. If any boot indicator byte in the MBR partition table is invalid, or if more than one indicates an active partition, the following message is displayed and the system stops:

I n v a l i d p a r t i t i o n t a b l e

24. If an active partition is found in the MBR, the partition boot record from the active partition is loaded and tested.
25. If the partition boot record can't be read successfully from the active partition within five retries because of read errors, the following message is displayed and the system stops:

E r r o r l o a d i n g o p e r a t i n g s y s t e m

26. The hard disk's partition boot record is tested for a signature. If it does not contain a valid signature of 55AAh as the last two bytes in the sector, the following message is displayed and the system stops:

M i s s i n g o p e r a t i n g s y s t e m

27. The volume boot record is executed as a program. This program looks for and loads the operating system kernel or system files. If the volume boot record can't find or load the system files, or if a problem was encountered loading them, one of the following messages appears:

N o n - S y s t e m d i s k o r d i s k e r r o r
R e p l a c e a n d s t r i k e a n y k e y w h e n r e a d y

N o n - S y s t e m d i s k o r d i s k e r r o r
R e p l a c e a n d p r e s s a n y k e y w h e n r e a d y

I n v a l i d s y s t e m d i s k _
R e p l a c e t h e d i s k , a n d t h e n p r e s s a n y k e y

D i s k B o o t f a i l u r e

D i s k I / O E r r o r

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

From this point forward, what happens depends on which operating system you have. The operating-system-dependent boot procedures are discussed in the next several sections.

The DOS Boot Process

1.

The initial system file (called **IO.SYS** or **IBMBIO.COM**) is executed.

2.

The initialization code in **IO.SYS/IBMBIO.COM** copies itself into the highest region of contiguous DOS memory and transfers control to the copy. The initialization code copy then relocates **MSDOS.SYS** over the portion of **IO.SYS** in low memory that contains the initialization code because the initialization code no longer needs to be in that location.

3.

The initialization code executes **MSDOS.SYS** (or **IBMDOS.COM**), which initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.

4.

The full DOS file system is active, and control is returned to the **IO.SYS** initialization code.

5.

The **IO.SYS** initialization code reads the **CONFIG.SYS** file multiple times.

6.

When loading **CONFIG.SYS**, the **DEVICE** statements are first processed in the order in which they appear. Any device driver files named in those **DEVICE** statements are loaded and executed. Then, any **INSTALL** statements are processed in the order in which they appear; the programs named are loaded and executed. The **SHELL** statement is processed and loads the specified command processor with the specified parameters. If the **CONFIG.SYS** file contains no **SHELL** statement, the default **\COMMAND.COM** processor is loaded with default parameters. Loading the command processor overwrites the initialization code in memory (because the job of the initialization code is finished).

During the final reads of **CONFIG.SYS**, all the remaining statements are read and processed in a predetermined order. Thus, the order of appearance for statements other than **DEVICE**, **INSTALL**, and **SHELL** in **CONFIG.SYS** is of no significance.

7.

If **AUTOEXEC.BAT** is present, **COMMAND.COM** loads and runs **AUTOEXEC.BAT**. After the commands in **AUTOEXEC.BAT** have been executed, the DOS prompt appears (unless **AUTOEXEC.BAT** calls an application program or shell of some kind, in which case the user might operate the system without ever seeing a DOS prompt).

8.

If no **AUTOEXEC.BAT** file is present, **COMMAND.COM** executes the internal **DATE** and **TIME** commands, displays a copyright message, and displays the DOS prompt.

Some minor variations from this scenario are possible, such as those introduced by other ROM programs in the various adapters that might be plugged into an expansion slot. Also, depending on the exact ROM BIOS programs involved, some of the error messages and sequences can vary. Generally, however, a computer follows this chain of events while "coming to life."

You can modify the system startup procedures by altering the **CONFIG.SYS** and **AUTOEXEC.BAT** files. These files control the configuration of DOS and allow special startup programs to be executed every time the system starts.

The Windows 9x/Me Boot Process

Knowing exactly how Windows 9x and Millennium Edition (Me) load and start can be helpful when troubleshooting startup problems. The Windows 9x boot process can be broken into three phases:

- The **I.O. SYS** file is loaded and run. (Windows 9x's **I.O. SYS** combines the functions of DOS's **I.O. SYS** and **MSDOS. SYS**.)
- Real-mode configuration takes place.
- The **WIN.COM** file is loaded and run.

Phase 1 Loading and Running the **I.O. SYS** File

1.

The initialization code initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.

2.

The file system is activated, and control is returned to the **I.O. SYS** initialization code.

3.

The **Starting Windows** message is displayed for $<n>$ seconds, or until you press a Windows function key. The amount of time the message is displayed is determined by the **BootDelay=<n>** line in the **MSDOS. SYS** file; the default is 2 seconds.

4.

The **I.O. SYS** initialization code reads the **MSDOS. SYS** configuration file. If you have multiple hardware profiles, you receive the following message and must choose a hardware configuration to use:

Windows cannot determine what configuration your computer is in.

5.

The **LOGO. SYS** file is loaded and displays a startup image onscreen.

6.

If the **DRVSPACE. INI** or **DBLSPACE. INI** file exists, it is loaded into memory. **IO. SYS** also automatically loads **HIMEM. SYS**, **IFSHLP. SYS**, and **SETVER. EXE**.

7.

The **IO. SYS** file checks the system Registry files (**SYSTEM. DAT** and **USER. DAT**) for valid data.

8.

IO. SYS opens the **SYSTEM. DAT** file. If the **SYSTEM. DAT** file is not found, the **SYSTEM. DAO** file is used for startup. If Windows 9x/Me starts successfully, the **SYSTEM. DAO** file is copied to the **SYSTEM. DAT** file.

9.

The **DBLBUFF. SYS** file is loaded if the **DoubleBuffer=1** is in the **MSDOS. SYS** file or if double buffering is enabled under the following Registry key:

HKLM\System\CurrentControlSet\Control\WinBoot\DoubleBuffer

Note

Windows 9x Setup automatically enables double buffering if it detects that it is required.

10.

If you have multiple hardware profiles, the hardware profile you chose is loaded from the Registry.

11.

In Windows 9x/Me, the system looks in the Registry's **Hkey_Local_Machine\System\CurrentControlSet** key to load the device drivers and other parameters specified there before executing the **CONFIG. SYS** file.

Phase 2Real-Mode Configuration

Some older hardware devices and programs require that drivers or files be loaded in real mode (16-bit mode) for them to work properly. To ensure backward compatibility, Windows 9x processes the **CONFIG. SYS** and **AUTOEXEC. BAT** files if they exist:

1.

The **CONFIG. SYS** file is read if it exists, and the statements within are processed, including the loading of drivers into memory. If the **CONFIG. SYS** file does not exist, the **IO. SYS** file loads the following

required drivers:

I FSHLP. SYS

HI MEM. SYS

SETVER. EXE

I O. SYS obtains the location of these files from the **Wi nBootDi r=** line of the **MSDOS. SYS** file and must be on the hard disk.

2.

Windows reserves all global upper memory blocks (UMBs) for Windows 9x operating system use or for expanded memory support using the Expanded Memory Specification (EMS).

3.

The **AUTOEXEC. BAT** file is processed if present, and any terminate-and-stay resident (TSR) programs listed within are loaded into memory.

Phase 3 Loading and Running the **WI N. COM** File

1.

The **WI N. COM** file is loaded and run.

2.

The **WI N. COM** file accesses the **VMM32. VXD** file. If enough RAM is available, the **VMM32. VXD** file loads into memory; otherwise, it is accessed from the hard disk (resulting in a slower startup time).

3.

The real-mode virtual device driver loader checks for duplicate virtual device drivers (VxDs) in the **WI NDOWS\SYSTEM\VMM32** folder and the **VMM32. VXD** file. If a VxD exists in both the **WI NDOWS\SYSTEM\VMM32** folder and the **VMM32. VXD** file, the duplicate VxD is "marked" in the **VMM32. VXD** file so that it is not loaded.

4.

VxDs not already loaded by the **VMM32. VXD** file are loaded from the **[386 Enh]** section of the **WI NDOWS\SYSTEM. INI** file.

Required VxDs

Some VxDs are required for Windows to run properly. These required VxDs are loaded automatically and do not require a Registry entry. Windows 9x requires the following VxDs:

BIOSXLAT	CONFIGMG	DYNAPAGE	DOSMGR
EBIOS	IFSMGR	INT13	IOS
PAGESWAP	SHELL	V86MMGR	VCD
VCACHE	VCOMM	VCOND	VDD
VDMAD	VFAT*VKD	VMCPD	VPICD
VTD	VTDAPI	VWIN32	VXDLDR

5.

The real-mode virtual device driver loader checks that all required VxDs loaded successfully. If not, it attempts to load the drivers again.

6.

After the real-mode virtual device driver loading is logged, driver initialization occurs. If any VxDs require real-mode initialization, they begin their processes in real mode.

7.

VMM32 switches the computer's processor from real mode to protected mode.

8.

A three-phase VxD initialization process occurs in which the drivers are loaded according to their InitDevice instead of the order in which they are loaded into memory.

9.

After all the VxDs are loaded, the **KRNL32.DLL**, **GDI.EXE**, **USER.EXE**, and **EXPLORER.EXE** (the default Windows 9x GUI shell) files are loaded.

10.

If a network is specified, load the network environment and multiuser profiles. The user is prompted to log on to the installed network. Windows 9x/Me enables multiple users to save their custom desktop settings. When a user logs on to Windows, her desktop settings are loaded from the Registry. If the user does not log on, the desktop configuration uses a default desktop.

11.

Programs in the StartUp group and the **RunOnce** Registry key are run during the last phase of the startup process. After each program in the **RunOnce** Registry key is started, the program is removed from the key.

Windows NT/2000/XP Startup

When you start a Windows NT, 2000, or XP system (which are all based on the same set of integral code), the boot process is different from that of a DOS or Windows 9x/Me system. Instead of the **IO.SYS** and **MSDOS.SYS** files used by 9x/Me, Windows NT/2000/XP use an OS loader program called Ntldr.

The basic Windows NT/2000/XP startup process is described in the following step-by-step procedures:

1. *The partition boot sector loads Ntldr (NT Loader).* It then switches the processor to protected mode, starts the file system, and reads the contents of **Boot.ini**. The information in **Boot.ini** determines the startup options and initial boot menu selections (dual-booting, for example). If dual-booting is enabled, and a non-NT/2000/XP OS is chosen, **Bootsec.dos** is loaded. If SCSI drives are present, **Ntbootdd.sys** is loaded, which contains the SCSI boot drivers.
2. **Ntdetect.com** *gathers hardware configuration data and passes this information to Ntldr.* If more than one hardware profile exists, Windows uses the correct one for the current configuration. If the ROM BIOS is ACPI compliant, Windows uses ACPI to enumerate and initialize devices.
3. *The kernel loads.* Ntldr passes information collected by **NTDetect.com** to **Ntoskrnl.exe**. Ntoskrnl then loads the kernel, Hardware Abstraction Layer (**Hal.dll**), and Registry information. An indicator near the bottom of the screen details progress.
4. *Drivers load and the user logs on.* Networking-related components (for example, TCP/IP) load simultaneously with other services and the **Begin Logon** prompt appears onscreen. After a user logs on successfully, Windows updates the Last Known Good Configuration information to reflect the current configuration state.
5. *Plug and Play detects and configures new devices.* If new devices are detected, they are assigned resources. Windows extracts the necessary driver files from **Driver.cab**. If the driver files are not found, the user is prompted to provide them. Device detection occurs simultaneously with the operating system logon process.

The following files are processed during Windows NT/2000/XP startup:

- **Ntldr**
- **Boot.ini**
- **Bootsec.dos** (multiple-boot systems only)
- **Ntbootdd.sys** (loaded only for SCSI drives)
- **Ntdetect.com**

- `Ntoskrnl.exe`
- `Hal.dll`
- Files in `systemroot\System32\Config` (Registry)
- Files in `systemroot\System32\Drivers` (drivers)

Note

If you see error messages during startup or your system doesn't start properly, restart the system, press the F8 key (Windows 2000/XP only) to open the startup menu, and select Enable Boot Logging to create a file called `Ntbtlog.txt`. This file records events during startup and can help you determine which files or processes are not loading correctly.

PC Maintenance Tools

To troubleshoot and repair PC systems properly, you need a few basic tools. If you intend to troubleshoot and repair PCs professionally, there are many more specialized tools you will want to purchase. These advanced tools enable you to more accurately diagnose problems and make jobs easier and faster. The basic tools that should be in every troubleshooter's toolbox are as follows:

- Simple hand tools for basic disassembly and reassembly procedures, including a flat blade and Phillips screwdrivers (both medium and small sizes), tweezers, an IC extraction tool, and a parts grabber or hemostat. Most of these items are included in \$10-\$20 starter toolkits found at most computer stores.
- Diagnostics software and hardware for testing components in a system.
- A multimeter that provides accurate measurements of voltage and resistance, as well as a continuity checker for testing cables and switches.
- Chemicals, such as contact cleaners; component freeze sprays; and compressed air for cleaning the system.
- Foam swabs, or lint-free cotton swabs if foam isn't available.
- Small nylon wire ties for "dressing" or organizing wires.

Some environments also might have the resources to purchase the following devices, although they're not required for most work:

- Memory-testing machines, used to evaluate the operation of single inline memory modules (SIMMs), dual inline memory modules (DIMMs), Rambus inline memory modules (RIMMs), or double data rate (DDR) DIMMs
- Serial and parallel loopback (or wrap) plugs to test serial and parallel ports
- A network cable scanner (if you work with networked PCs)
- A serial breakout box (if you use systems that operate over serial cables, such as Unix dumb terminals)
- A POST card (if you work with computers running DOS or other non-Windows operating systems, you might prefer to get a POST card that can also display IRQs and DMAs in use)

In addition, an experienced troubleshooter will probably want to have soldering and desoldering tools to fix bad serial cables. These tools are discussed in more detail in the following sections.

Hand Tools

When you work with PC systems, the tools required for nearly all service operations are simple and inexpensive. You can carry most of the required tools in a small pouch. Even a top-of-the-line "master mechanics" set fits inside a briefcase-sized container. The cost of these toolkits ranges from about \$20 for a small service kit to \$500 for one of the briefcase-sized deluxe kits. Compare these costs with what might be necessary for an automotive technician. An automotive service technician would have to spend \$5,000 \$10,000 or more for a complete set of tools. Not only are PC tools much less expensive, but I can tell you from experience that you don't get nearly as dirty working on computers as you do working on cars.

In this section, you learn about the tools required to assemble a kit that is capable of performing basic, board-level service on PC systems. One of the best ways to start such a set of tools is to purchase a small kit sold especially for servicing PCs.

[Figure 22.2](#) shows some of the basic tools you can use to work on PCs. Many of these tools can be found in one of the small PC toolkits that sell for about \$20.

Figure 22.2. The basic tools you need to work on your PC are shown here.

Note

Some tools aren't recommended because they are of limited use. However, they normally come with these types of kits.

You use nut drivers to remove the hexagonal-headed screws that secure the system-unit covers, adapter boards, disk drives, and power supplies in most systems. The nut drivers work much better than conventional screwdrivers.

Because some manufacturers have substituted Phillips-head screws for the more standard hexagonal-head screws, standard screwdrivers can be used for those systems. If slotted screws are used, they should be removed and replaced with Torx (preferred), hex, or Phillips-head screws that capture the driver tool and prevent it from slipping off the head of the screw. It is especially important never to allow slotted screws to be used on or near a motherboard because a flat-bladed screwdriver can very easily slip and damage the board.

Caution

When working in a cramped environment such as the inside of a computer case, screwdrivers with magnetic tips can be a real convenience, especially for retrieving that screw you dropped into the case. However, although I have used these types of screwdrivers many times with no problems, you should be aware of the damage a magnetic field can cause to magnetic storage devices such as floppy disks. Laying the screwdriver down on or near a floppy can damage the data on the disk. Fortunately, floppy disks aren't used that much anymore. Hard drives are shielded by a metal case; CD/DVD drives are not affected because they work optically; and memory and other chips are not affected by magnetic fields (unless they are magnitudes

stronger than what you'll see in a hand tool).

Chip-extraction and insertion tools are rarely needed these days because memory chips are mounted on SIMMs, RIMMs, or DIMMs and processors use zero insertion force (ZIF) sockets or other user-friendly connectors; however, in some cases they can be used as general-purpose prying or grabbing tools. The ZIF socket has a lever that, when raised, releases the grip on the pins of the processor, enabling you to easily lift it out with your fingers.

◀◀ See "[Zero Insertion Force](#)," p. [89](#).

However, if you work with older systems, you can use a chip extractor to install or remove memory chips (or other smaller chips) without bending any pins on the chip (see [Figure 22.3](#)). Usually, you pry out larger chips, such as microprocessors or ROMs, with the small screwdriver. Larger processors up through the 486 might require a chip extractor if they are mounted in the older low insertion force (LIF) socket. These chips have so many pins on them that a large amount of force is required to remove them, despite the fact that they call the socket "low insertion force." If you use a screwdriver on a large physical-size chip such as a 486, you risk cracking the case of the chip and permanently damaging it. The chip extractor tool for removing these chips has a very wide end with tines that fit between the pins on the chip to distribute the force evenly along the chip's underside. This minimizes the likelihood of breakage. Most of these types of extraction tools must be purchased specially for the chip you're trying to remove.

Figure 22.3. The chip extractor (left) is used to remove an individual RAM or ROM chip from a socket, but it would not be useful for a larger processor chip. Use an extractor such as the one on the right for extracting socketed processors if the processor does not use a ZIF socket.

Tip

The older-style chip extractor shown on the left in [Figure 22.3](#) does have another use as a keycap extractor. In fact, for this role it works quite well. By placing the tool over a keycap on a keyboard and squeezing the tool so the hooks grab under the keycap on opposite sides, you can cleanly and effectively remove the keycap from the keyboard without damage. This works much better than trying to pry off the caps with a screwdriver, which often results in damaging them or sending them flying across the room.

The tweezers and parts grabber can be used to hold any small screws or jumper blocks that are difficult to hold in your hand. The parts grabber is especially useful when you drop a small part into the interior of a system; usually, you can remove the part without completely disassembling the system (see [Figure 22.4](#)).

Figure 22.4. The parts grabber has three small metal prongs that can be extended to grab a part.

Finally, the Torx driver is a star-shaped driver that matches the special screws found in most systems (see [Figure 22.5](#)). Torx screws are vastly superior to other types of screws for computers because they offer greater grip and the tool is much less likely to slip. The most common cause of new motherboard failures is the use of slotted screwdrivers that slip off the screw head, scratching (and damaging) the motherboard. I never allow slotted screws or a standard flat-bladed screwdriver anywhere near the interior of my systems. You also can purchase tamperproof Torx drivers that can remove Torx screws with the tamper-resistant pin in the center of the screw. A tamperproof Torx driver has a hole drilled in it to allow clearance for the pin. Torx drivers come in a number of sizes, the most common being the T-10 and T-15.

Figure 22.5. A Torx driver and bit.

Although this basic set is useful, you should supplement it with some other basic tools, such as

- *Electrostatic discharge (ESD) protection kit.* This includes a wrist strap and mat (such as those from Radio Shack or Jensen Tools) and prevents static damage to the components on which you are working. These kits consist of a wrist strap with a ground wire and a specially conductive mat with its own ground wire. You also can get just the wrist strap or the antistatic mat separately. In areas or times of the season when there is low humidity, static charges are much more likely to build up as you move, increasing the need for ESD protection. A wrist strap is shown in [Figure 22.6](#).

Figure 22.6. A typical ESD wrist strap clipped to a nonpainted surface in the case chassis.

- *Needle-nose pliers and hemostats (curved and straight).* These are great for gripping small items and jumpers, straightening bent pins, and so on.
- *Electric screwdriver.* Combined with hex, Phillips, standard, and Torx bit sets, this tool really speeds up repetitive disassembly/assembly. Black and Decker offers the VersaPak VP730 (www.blackanddecker.com).
- *Flashlight.* You should preferably use a high-tech LED unit such as those from Lightwave (www.longlight.com), which enable you to see inside dark systems and are easy on batteries.
- *Wire cutter or stripper.* This is useful for making or repairing cables or wiring. For example, you'd need this (along with a crimping tool) to make 10BASE-T Ethernet cables using UTP cable and RJ-45 connectors (refer to [Chapter 18](#), "Local Area Networking").
- *Vise or clamp.* This is used to install connectors on cables, crimp cables to the shape you want, and hold parts during delicate operations. In addition to the vise, Radio Shack sells a nifty "extra hands" device that has two movable arms with alligator clips on the end. This type of device is very useful for making cables or for other delicate operations during which an extra set of hands to hold something might be useful.
- *Metal file.* This is used to smooth rough metal edges on cases and chassis and to trim the face-plates on disk drives for a perfect fit.
- *Markers, pens, and notepads.* Use these for taking notes, marking cables, and so on.
- *Windows 98/98SE or Me startup floppy.* These disks have DOS 7.1 or 8.0 and real-mode CD-ROM/DVD drivers, which can be used to boot test the system and possibly load other software.
- *Windows 2000/XP original (bootable) CD.* This can be used to boot test the system from a CD-ROM/DVD drive, attempt system recovery, OS installation, or to run other software. Microsoft also has a downloadable set of floppy disks (six disks for Windows XP) available at support.microsoft.com; however, most systems capable of running Windows 2000 or XP should be able to boot from the CD.
- *Diagnostics software.* This commercial, shareware, or freeware software can be used for PC hardware verification and testing.
- *Power on self test (POST) card such as the Post Probe from www.micro2000.com.* This is used for displaying POST diagnostics codes on systems with fatal errors.
- *Nylon cable-ties.* These are used to help in routing and securing cables; neatly routed cables help to

improve airflow in the system.

- *Digital pocket multimeter (such as those from Radio Shack).* This is used for checking power supply voltages, connectors, and cables for continuity.
- *Cleaning swabs, canned air (dust blower), and contact cleaner chemicals.* These are used for cleaning, lubricating, and enhancing contacts on circuit boards and cable connections. Products include those from www.chemtronics.com, as well as contact enhancer chemicals such as Stabilant 22a (www.stabilant.com).
- *Data transfer cables and adapters.* These are used for quickly connecting two systems and transferring data from one system to another. This includes serial and parallel cables (often called Laplink, Interlink, or Direct Cable Connect cables); Ethernet crossover cables; as well as more specialized USB-to-Ethernet, USB-to-USB, or USB-to-parallel adapters.
- *2 1/2" ATA drive cables and adapters.* These are used for connecting 2 1/2" ATA drives to laptop or desktop systems for transferring or recovering data. This includes 44-pin (2 1/2") ATA-to-40-pin (3 1/2") ATA ribbon cable/power adapters, 44-pin ATA-to-USB/FireWire adapters, and 2 1/2" USB/FireWire external drive enclosures.
- *External mouse, keyboard, and keyboard/mouse PS/2 Y adapter.* These are useful for operating a system in which the existing keyboard or pointing device is defective or difficult to use. The Y adapter is required on most laptops to use an external PS/2 keyboard alone or a PS/2 keyboard and mouse together.
- *USB powered hub, USB/FireWire cable adapter.* This is useful for connecting external USB devices, especially USB keyboards, mice, and external drives. The cable adapters and gender changers are recommended for connecting different types of USB and FireWire devices.
- *Spare screws, jumpers, standoffs, and so on.* These are used in case some go missing or are lost from the system you are working on.
- *Spare CR-2032 lithium coin cell batteries.* These are used as the CMOS RAM batteries in most systems, so it is a good idea to have a replacement or two on hand. Although a number of CR20xx battery types are available, most systems use the CR2032.

Safety

Before working on a system, there are certain safety procedures that should be followed. Some are to protect you, whereas others are to protect the system on which you are working.

From a personal safety point of view, there really isn't that much danger in working on a PC. Even if it is open with the power on, PCs run on only 3.3, 5, and 12 volts, meaning no dangerous, life-threatening voltages are present. However, dangerous voltages do exist inside the power supply and monitor. Most power supplies have 400 volts present at some points internally, and color displays have between 50,000 and 100,000 volts on the CRT! Normally, I treat the power supply and monitor as components that are replaced and not repaired, and I do not recommend you open either of them unless you really know what you are doing around high voltages.

Before working on a PC, you should unplug it from the wall. This is not really to protect you so much as it is to protect the system. A modern ATX form factor system is always partially running that is, as long as the system is plugged in. So, even if it is off, standby voltages are present. To prevent damage to the motherboard, video card, and other cards, the system should be completely unplugged. If you accidentally turn the system all the way on, and plug in or remove a card, you can fry the card or motherboard.

Electrostatic discharge protection is another issue. While working on a PC, you should wear an ESD wrist strap that is clipped to the chassis of the machine (see [Figure 22.6](#)). This ensures that you and the system remain at the same electrical potential and prevents static electricity from damaging the system as you touch it. Some people feel that the system should be plugged in to provide an earth ground. That is not a good idea at all, as I previously mentioned. No "earth" ground is necessary; all that is important is that you and the system remain at the same electrical potential, which is accomplished via the strap. Another issue

for personal safety is the use of a commercially available wrist strap, rather than making your own. Commercially made wrist straps feature an internal 1-meg ohm resistor designed to protect you. The resistor ensures that you are not the best path to ground should you touch any "hot" wire.

When you remove components from the system, they should be placed on a special conductive antistatic mat, which is also a part of any good ESD protection kit. The mat is also connected via a wire and clip to the system chassis. Any components removed from the system, especially items such as the processor, the motherboard, adapter cards, disk drives, and so on, should be placed on the mat. The connection between you, the mat, and the chassis will prevent any static discharges from damaging the components.

Note

It is possible (but not recommended) to work without an ESD protection kit if you're disciplined and careful about working on systems. If you don't have an ESD kit available, you can discharge yourself by touching any exposed metal on the chassis or case.

The ESD kits, as well as all the other tools and much more, are available from a variety of tool vendors. Specialized Products Company and Jensen Tools are two of the most popular vendors of computer and electronic tools and service equipment. Their catalogs show an extensive selection of very high-quality tools. (These companies and several others are listed in the Vendor List on the accompanying disc.) With a simple set of hand tools, you will be equipped for nearly every PC repair or installation situation. The total cost of these tools should be less than \$150, which is not much considering the capabilities they provide.

A Word About Hardware

This section discusses some problems you might encounter with the hardware (screws, nuts, bolts, and so on) used in assembling a system.

Types of Hardware

One of the biggest aggravations you encounter in dealing with various systems is the different hardware types and designs that hold the units together.

For example, most systems use screws that fit 1/4" or 3/16" hexagonal nut drivers. IBM used these screws in all its original PC, XT, and AT systems, and most other system manufacturers use this standard hardware as well. Some manufacturers use different hardware, however. Compaq, for example, uses Torx screws extensively in many of its systems. A Torx screw has a star-shaped hole driven by the correct-size Torx driver. These drivers carry size designations such as T-8, T-9, T-10, T-15, T-20, T-25, T-30, and T-40.

A variation on the Torx screw is the tamperproof Torx screw found in power supplies, monitors, hard drives, and other assemblies. These screws are identical to the regular Torx screws, except that a pin sticks up from the middle of the star-shape hole in the screw. This pin prevents the standard Torx driver from entering the hole to grip the screw; a special tamperproof driver with a corresponding hole for the pin is required. An alternative is to use a small chisel to knock out the pin in the screw. Usually, a device sealed with these types of screws is considered to be a replaceable unit that rarely, if ever, needs to be opened.

Caution

Note that devices sealed with tamperproof Torx screws generally have high voltages or other dangers waiting inside, so being able to bypass these screws doesn't mean it's always a good idea. Be sure you know what you are doing before disassembling devices such as monitors and power supplies.

Many manufacturers also use the more standard slotted-head and Phillips-head screws. Slotted-head screws should *never* be used in a computer because the screwdriver can very easily slip and damage a board. Using tools on these screws is relatively easy, but tools do not grip these fasteners as well as hexagonal head or Torx screws do. In addition, the heads can be stripped more easily than the other types. Extremely cheap versions tend to lose bits of metal as they're turned with a driver, and the metal bits can fall onto the motherboard. Stay away from cheap fasteners whenever possible; the headaches of dealing with stripped screws aren't worth it.

Some system manufacturers now use cases that snap together or use thumb screws. These are usually advertised as "no-tool" cases because you literally do not need any tools to remove the cover and access the major assemblies.

To make an existing case tool-free, you can replace the normal case screws with metal or plastic thumbscrews. However, you still should always use metal screws to install internal components, such as adapter cards, disk drives, power supplies, and the motherboard, because the metal screws provide a ground point for these devices.

English Versus Metric

Another area of aggravation with hardware is the fact that two types of thread systems exist: English and metric. IBM used mostly English-threaded fasteners in its original line of systems, but many other manufacturers used metric-threaded fasteners.

The difference between the two becomes especially apparent with disk drives. American-manufactured drives typically use English fasteners, whereas drives made in Japan, Taiwan, and other Pacific Rim countries (where most disk drives are now made) typically use metric. Whenever you replace a floppy drive in an older PC, you encounter this problem. Try to buy the correct screws and any other hardware, such as brackets, with the drive because they might be difficult to find as separate items. Many drive manufacturers offer retail drive kits that include all the required mounting components. The OEM's drive manual lists the correct data about a specific drive's hole locations and thread size.

Tip

Before you discard an obsolete computer, remove the screws and other reusable parts, such as cover plates, jumper blocks, and so on. Label the bag or container with the name and model of the computer to help you more easily determine where else you can use the parts later.

Hard disks can use either English or metric fasteners; check your particular drive to see which type it uses. Most drives today use metric hardware.

Caution

Some screws in a system can be length-critical, especially screws used to retain hard disk drives. You can destroy some hard disks by using a mounting screw that's too long; the screw can puncture or dent the sealed disk chamber when you install the drive and fully tighten the screw. When you install a new drive in a system, always make a trial fit of the hardware to see how far the screws can be inserted into the drive before they interfere with its internal components. When in doubt, the drive manufacturer's OEM documentation will tell you precisely which screws are required and how long they should be. Most drives sold at retail include correct-length mounting screws, but OEM drives usually don't include screws or other hardware.

Test Equipment

In some cases, you must use specialized devices to test a system board or component. This test equipment is not expensive or difficult to use, but it can add much to your troubleshooting abilities.

Electrical Testing Equipment

I consider a voltmeter to be required gear for proper system testing. A multimeter can serve many purposes, including checking for voltage signals at various points in a system, testing the output of the power supply, and checking for continuity in a circuit or cable. An outlet tester is an invaluable accessory that can check the electrical outlet for proper wiring. This capability is useful if you believe the problem lies outside the computer system.

Loopback Connectors (Wrap Plugs)

For diagnosing serial- and parallel-port problems, you need loopback connectors (also called wrap plugs), which are used to circulate, or wrap, signals (see [Figure 22.7](#)). The plugs enable the serial or parallel port to send data to itself for diagnostic purposes.

Figure 22.7. Typical wrap plugs, including 25-pin and 9-pin serial and 25-pin parallel versions.

Various types of loopback connectors are available. To accommodate all the ports you might encounter, you need one for the 25-pin serial port, one for the 9-pin serial port, and one for the 25-pin parallel port. Many

companies, including IBM, sell the plugs separately, but be aware that you also need diagnostic software that can use them. Some diagnostic software products, such as Micro 2000's Micro-Scope, include loopback connectors with the product, or you can purchase them as an option for about \$30 a set. Note that there are some variations on how loopback connectors can be made, and not all versions work properly with all diagnostics software. You should therefore use the loopback connectors recommended by the diagnostics software you will be using.

IBM sells a special combination plug that includes all three connector types in one compact unit. The device costs about the same as a normal set of wrap plugs. If you're handy, you can even make your own wrap plugs for testing. I include wiring diagrams for the three types of wrap plugs in [Chapter 15](#), "I/O Interfaces from Serial and Parallel to IEEE 1394 and USB." In that chapter, you also will find a detailed discussion of serial and parallel ports.

Besides simple loopback connectors, you also might want to have a break-out box for your toolkit. A breakout box is a DB25 connector device that enables you to make custom temporary cables or even to monitor signals on a cable. For most PC troubleshooting uses, a "mini" breakout box works well and is inexpensive.

Meters

Some troubleshooting procedures require that you measure voltage and resistance. You take these measurements by using a handheld Digital Multi-Meter (DMM). The meter can be an analog device (using an actual meter) or a digital-readout device. The DMM has a pair of wires called test leads or probes. The test leads make the connections so that you can take readings. Depending on the meter's setting, the probes measure electrical resistance, direct-current (DC) voltage, or alternating-current (AC) voltage. [Figure 22.8](#) shows a typical DMM being used to test the +12V circuit on an ATX motherboard.

Figure 22.8. A typical digital multimeter tests a motherboard's +12V circuit.

Usually, each system-unit measurement setting has several ranges of operation. DC voltage, for example, usually can be read in several scales, to a maximum of 200 millivolts (mV), 2V, 20V, 200V, and 1,000V. Because computers use both +5V and +12V for various operations, you should use the 20V maximum scale for making your measurements. Making these measurements on the 200mV or 2V scale could "peg the meter" and possibly damage it because the voltage would be much higher than expected. Using the 200V or 1,000V scale works, but the readings at 5V and 12V are so small in proportion to the maximum that accuracy is low.

If you are taking a measurement and are unsure of the actual voltage, start at the highest scale and work your way down. Most of the better meters have autoranging capabilitythe meter automatically selects the best range for any measurement. This type of meter is much easier to operate. You simply set the meter to the type of reading you want, such as DC volts, and attach the probes to the signal source. The meter selects the correct voltage range and displays the value. Because of their design, these types of meters always have a digital display rather than a meter needle.

Caution

Whenever you are using a multimeter to test any voltage that could potentially be 50V or above (such as AC wall socket voltage), always use one hand to do the testing, not two. Either clip one lead to one of the sources and probe with the other or hold both leads in one hand.

If you hold a lead in each hand and accidentally slip, you can very easily become a circuit, allowing power to conduct or flow through you. When power flows from arm to arm, the path

of the current is directly across the heart. The heart muscle tends to quit working when subjected to high voltages. They're funny that way.

I prefer the small digital meters; you can buy them for only slightly more than the analog style, and they're extremely accurate and much safer for digital circuits. Some of these meters are not much bigger than a cassette tape; they fit in a shirt pocket. Radio Shack sells a good unit in the \$25 price range; the meter (refer to [Figure 22.8](#)) is a half-inch thick, weighs 3 1/2 ounces, and is digital and autoranging, as well. This type of meter works well for most, if not all, PC troubleshooting and test uses.

Caution

You should be aware that many analog meters can be dangerous to digital circuits. These meters use a 9V battery to power the meter for resistance measurements. If you use this type of meter to measure resistance on some digital circuits, you can damage the electronics because you essentially are injecting 9V into the circuit. The digital meters universally run on 3V5V or less.

Logic Probes and Logic Pulsers

A logic probe can be useful for diagnosing problems in digital circuits (see [Figure 22.9](#)). In a digital circuit, a signal is represented as either high (+5V) or low (0V). Because these signals are present for only a short time (measured in millionths of a second) or oscillate (switch on and off) rapidly, a simple voltmeter is useless. A logic probe is designed to display these signal conditions easily.

Figure 22.9. A typical logic probe.

Logic probes are especially useful for troubleshooting a dead system. By using the probe, you can determine whether the basic clock circuitry is operating and whether other signals necessary for system operation are present. In some cases, a probe can help you cross-check the signals at each pin on an integrated circuit chip. You can compare the signals present at each pin with the signals a known-good chip of the same type would show a comparison that is helpful in isolating a failed component. Logic probes also can be useful for troubleshooting some disk drive problems by enabling you to test the signals present on the interface cable or drive-logic board.

A companion tool to the probe is the logic pulser. A *pulser* is designed to test circuit reaction by delivering a logical high (+5V) pulse into a circuit, usually lasting from 1 1/2 to 10 millionths of a second. Compare the reaction with that of a known-functional circuit. This type of device normally is used much less frequently than a logic probe, but in some cases it can be helpful for testing a circuit.

Outlet (Receptacle) Testers

Outlet testers (also called *receptacle testers*) are very useful test tools. These simple, inexpensive devices, sold in hardware stores, test electrical outlets. You simply plug in the device, and three LEDs light up in various combinations, indicating whether the outlet is wired correctly (see [Figure 22.10](#)).

Figure 22.10. A typical outlet/receptacle tester.

Although you might think that badly wired outlets would be a rare problem, I have seen a large number of installations in which the outlets were wired incorrectly. Most of the time, the problem is in the ground wire. An improperly wired outlet can result in unstable system operation, such as random parity checks and lockups. With an improper ground circuit, currents can begin flowing on the electrical ground circuits in the system. Because the system uses the voltage on the ground circuits as a comparative signal to determine whether bits are 0 or 1, a floating ground can cause data errors in the system.

Caution

Even if you use a surge protector, it will not protect your system from an improperly wired outlet. Therefore, you still should use an outlet tester to ensure your outlet is computer friendly.

Once, while running one of my PC troubleshooting seminars, I used a system that I literally could not approach without locking it up. Whenever I walked past the system, the electrostatic field generated by my body interfered with the system and the PC locked up, displaying a parity-check error message. The

problem was that the hotel at which I was giving the seminar was very old and had no grounded outlets in the room. The only way I could prevent the system from locking up was to run the class in my stocking feet because my leather-soled shoes were generating the static charge.

Other symptoms of bad ground wiring in electrical outlets are continual electrical shocks when you touch the case or chassis of the system. These shocks indicate that voltages are flowing where they should not be. This problem also can be caused by bad or improper grounds within the system. By using the simple outlet tester, you can quickly determine whether the outlet is at fault.

If you just walk up to a system and receive an initial shock, it's probably only static electricity. Touch the chassis again without moving your feet. If you receive another shock, something is very wrong. In this case, the ground wire actually has voltage applied to it. You should check the outlet with an outlet/receptacle tester and, if it fails, have a professional electrician check the outlet immediately. If the outlet checks out, the power supply inside the PC is probably failing (even though the system might seem to be otherwise running normally). In such a case, it should be replaced.

Although I recommend using an outlet/receptacle tester, if you don't have one handy, you can test an outlet using a multimeter. First, remember to hold both leads in one hand. Test from one blade hole to another. This should read between 110V and 125V, depending on the electrical service in the area. Then, check from each blade to the ground (the round hole). One blade hole, the smaller one, should show a voltage almost identical to the one you got from the blade-hole to blade-hole test. The larger blade hole when measured to ground should show less than 0.5V.

Because ground and neutral are supposed to be tied together at the electrical panel, a large difference in these readings indicates that they are not tied together. However, small differences can be accounted for by current from other outlets down the line flowing on the neutral, when there isn't any on the ground.

If you don't get the results you expect, call an electrician to test the outlets for you. More weird computer problems are caused by improper grounding and other power problems than people like to believe.

Memory Testers

I now consider a memory test machine an all-but-mandatory piece of equipment for anyone serious about performing PC troubleshooting and repair as a profession. The tester is a small device designed to evaluate SIMMs, DIMMs, RIMMs, and other types of memory modules, including individual chips such as those used as cache memory. These testers can be somewhat expensive, costing upward of \$1,000\$2,500 or more, but these machines are the only truly accurate way to test memory.

Without one of these testers, you are reduced to testing memory by running a diagnostic program on the PC and testing the memory as it is installed. This can be very problematic because the memory diagnostic program can do only two things to the memory: write and read. A SIMM/DIMM/RIMM tester can do many things a memory diagnostic running in a PC can't do, such as

- Identify the type of memory
- Identify the memory speed
- Identify whether the memory has parity or is using bogus parity emulation
- Vary the refresh timing and access speed timing
- Locate single bit failures
- Detect power- and noise-related failures
- Detect solder opens and shorts
- Isolate timing-related failures
- Detect data retention errors

No conventional memory diagnostic software can do these things because it must rely on the fixed access parameters set up by the memory controller hardware in the motherboard chipset. This prevents the software from being capable of altering the timing and methods used to access the memory. You might have memory that fails in one system and works in another when the chips are actually bad. This type of intermittent problem is almost impossible to detect with diagnostic software.

The bottom line is that there is no way you can test memory with true accuracy while it is installed in a PC; a memory tester is required for comprehensive and accurate testing. The price of a memory tester can be justified very easily in a shop environment where a lot of PCs are tested because many software and hardware upgrades today require the addition of new memory. With the large increases in the amount of memory in today's systems and the stricter timing requirements of newer motherboard designs, it has become even more important to be able to identify or rule out memory as a cause of system failure. One company manufacturing memory testers I recommend is Tanisys Technology; its Darkhorse Systems line of memory testers can handle virtually every type of memory on the market. See the Vendor List on this book's disc for more information. Also, see [Chapter 6](#), "Memory," for more information on memory in general.

Special Tools for the Enthusiast

All the tools described so far are commonly used by most technicians. However, a few additional tools do exist that a true PC enthusiast might want to have.

Electric Screwdriver

Perhaps the most useful tool I use is an electric screwdriver. It enables me to disassemble and reassemble a PC in record time and makes the job not only faster but easier as well. I like the type with a clutch you can use to set how tight it will make the screws before slipping; such a clutch makes it even faster to use. If you use the driver frequently, it makes sense to use the type with replaceable, rechargeable batteries, so when one battery dies you can quickly replace it with a fresh one.

Caution

Note that using an electric screwdriver when installing a motherboard can be dangerous because the bit can easily slip off the screw and damage the board. A telltale series of swirling scratches near the screw holes on the board can be the result, for which most manufacturers rightfully deny a warranty claim. Be especially careful if your motherboard is retained with Phillips-head screws because they are extremely easy for the bit to slip out of. Normally, I recommend using only Torx-head or hex-head screws to retain the motherboard because they are far more resistant to having the bit slip out and cause damage.

With the electric screwdriver, I recommend getting a complete set of English and metric nut driver tips as well as various sizes of Torx, flat-head, and Phillips-head screwdriver tips.

Tamperproof Torx Bits

Any devices such as power supplies and monitors are held together with tamperproof Torx screws. Tamperproof Torx driver sets are available from any good electronics tool supplier.

Temperature Probe

Determining the interior temperature of a PC is often useful when diagnosing whether heat-related issues are causing problems. This requires some way of measuring the temperature inside the PC, as well as the ambient temperature outside the system. The simplest and best tool I've found for the job is the digital thermometers sold at most auto parts stores for automobile use. They are designed to read the temperature inside and outside the car and normally come with an internal sensor, as well as one at the end of a length of wire.

With this type of probe, you can run the wired sensor inside the case (if it is metal, make sure it does not directly touch the motherboard or other exposed circuits where it might cause a short) with the wires slipped through a crack in the case or out one of the drive bays. Then, with the system running you can take the internal temperature as well as read the room's ambient temperature. Normally, the maximum limit for internal temperature should be 110°F (43°C) or less. If your system is running near or above that temperature, problems can be expected. You also can position the probe in the system to be near any heat producing devices, such as the processor, video card, and so on, to see the effect of the device. Probing the temperature with a device such as this enables you to determine whether additional cooling is necessary (that is, adding more cooling fans to the case) and enables you to check to see whether the added fans are helping.

Infrared Thermometer

Another useful temperature tool is a noncontact infrared (IR) thermometer, which is a special type of sensor that can measure the temperature of an object without physically touching it (see [Figure 22.11](#)). You can take the temperature reading of an object in seconds by merely pointing the handheld device at the object you want to measure and pulling a trigger.

Figure 22.11. A noncontact infrared thermometer.

An IR thermometer works by capturing the infrared energy naturally emitted from all objects warmer than absolute zero (0° Kelvin). Infrared energy is a part of the electromagnetic spectrum with a frequency below that of visible light, which means it is invisible to the human eye. Infrared wavelengths are between 0.7 microns and 1,000 microns (millionths of a meter), although infrared thermometers typically measure radiation in the range 0.714 microns.

Because IR thermometers can measure the temperature of objects without touching them, they are ideal for measuring chip temperatures in a running system especially the temperature of the CPU heatsink. By merely pointing the device at the top of the CPU and pulling the trigger, you can get a very accurate measurement in about 1 second. To enable more accuracy in positioning, many IR thermometers incorporate a laser pointer, which is used to aim the device.

IR thermometers are designed to measure IR radiation from a device; they can't be used to measure air temperature. The sensors are specifically designed so that the air between the sensor and target does not affect the temperature measurement.

Although several IR thermometers are available on the market, I use and recommend the Raytek (www.raytek.com) MiniTemp series, which consists of the MT2, MT4, and MT6. These units are all but identical; however, the MT4 includes a laser pointer for aiming and the MT6 includes a protective boot, improved distance to spot ratings (10:1 instead of 8:1), and a range of up to 6 feet (instead of 4 feet). The MT2 is capable of measuring temperatures between 0° and 525°F (18°270°C) in one-half of a second with an accuracy of about plus or minus 3°F (2°C). The MT4 tops out at 750°F (400°C), and the MT6 can measure temperatures between 20° and 932°F (30°500°C). They cost \$80\$100 and are available from NAPA auto parts stores (these devices have many uses in automotive testing as well) and other tool outlets.

Large Claw-Type Parts Grabber

One of the more useful tools in my toolbox is a large claw-type parts grabber, normally sold in stores that carry automotive tools. Having one of these around has saved many hours of frustration digging back into a system or behind a desk for a loose or dropped screw.

These grabbers are very similar to the small claw-type grabber included with most PC toolkits, except they are much larger normally two feet or so in length. They can be useful if you drop a screw down inside a tower case, or even on the floor under or behind a desk or cabinet. Although magnetic parts grabbers are also available, I normally recommend the claw-type because using a powerful magnet near a computer can cause problems with any disk storage media you have about, or even the hard disk or CRT-type display.

[< PREVIOUS](#)[NEXT >](#)

Preventive Maintenance

Preventive maintenance is the key to obtaining years of trouble-free service from your computer system. A properly administered preventive maintenance program pays for itself by reducing problem behavior, data loss, and component failure and by ensuring a long life for your system. In several cases, I have "repaired" an ailing system with nothing more than a preventive maintenance session. Preventive maintenance also can increase your system's resale value because it will look and run better.

Developing a preventive maintenance program is important to everyone who uses or manages personal computer systems. The two types of preventive maintenance procedures are active and passive.

Passive preventive maintenance includes precautionary steps you can take to protect a system from the environment, such as using power-protection devices; ensuring a clean, temperature-controlled environment; and preventing excessive vibration. In other words, passive preventive maintenance means treating your system well and with care.

An *active* preventive maintenance program includes procedures that promote a longer, trouble-free life for your PC. This type of preventive maintenance primarily involves the periodic cleaning of the system and its components, as well as performing backups, antivirus and antispyware scans, and other software-related procedures. The following sections describe several active preventive maintenance procedures.

Active Preventive Maintenance Procedures

How often you should perform active preventive maintenance procedures depends on the system's environment and the quality of the system's components. If your system is in a dirty environment, such as a machine shop floor or a gas station service area, you might need to clean your system every three months or less. For normal office environments, cleaning a system every few months to a year is usually fine. However, if you open your system after one year and find dust bunnies inside, you should probably shorten the cleaning interval.

Other hard disk preventive maintenance procedures include making periodic backups of your data. Also, depending on which OS and file system you use, you should defragment hard disks at least once a month to maintain disk efficiency and speed.

The following is a sample weekly disk maintenance checklist:

- Back up any data or important files.
- Run a full system antivirus and antispyware scan. Before starting the scans, be sure to check for and install antivirus and antispyware software updates. Most of these programs have integrated update routines that automatically check for updates on a weekly or monthly basis, or at some other interval you choose.
- Run the Windows Disk Cleanup tool, which searches the system for files you can safely delete, such as
 - Files in the Recycle Bin
 - Temporary Internet files
 - Windows temporary files
 - Install programs for previously downloaded and installed programs

- System restore points except the most recent restore point
- Optional Windows components you are not using
- Installed programs you no longer use
- Finally, run a disk-defragmenting program.

About System Restore

System Restore is an automatic service in Windows Me, XP, and later versions that periodically creates restore points, which are snapshots of the Registry and certain other dynamic system files. These restore points do not include any user or application data and should therefore not be confused with, or used in place of, normal file or data backup procedures. The System Restore application (found in the Program menu under Accessories, System Tools) can be used to manually return a system to a previously created restore point, as well as to manually create a new restore point. You don't typically need to manually create restore points because they are automatically created at the following times:

- Every time you install an application
- Every time an update is installed with Automatic Updates
- Every time an update is installed with Windows Update
- Every time you install an unsigned driver
- Every 24 hours if the system is turned on, or if it has been more than 24 hours since the last restore point was created

Even though you don't usually need to create restore points manually, I do recommend creating a manual restore point before editing the Registry directly because that essentially creates a backup of the Registry you can restore if your edit causes problems.

The following are some monthly maintenance procedures you should perform:

- Create an operating system startup disk, or ensure that you have access to a bootable OS installation CD for recovery purposes.
- Check for and install any updated drivers for video cards, sound cards, modems, and other devices.
- Check for and install any operating system updates. If you have Automatic Updates turned on (recommended), this is done automatically for you.
- Clean the system, including the monitor screen, keyboard, CD/DVD drives, floppy drive, mouse, and so on.
- Check that all system fans are operating properly, including the CPU heatsink, power supply, and any chassis fans. You can use the system BIOS readout of fan speeds to perform a quick check. Open the system to examine any fans that aren't working or are running more slowly than normal.

System Backups

One of the most important preventive maintenance procedures is the performance of regular system backups. A sad reality in the computer repair and servicing world is that hardware can always be repaired or replaced, but data cannot. Many hard disk troubleshooting and service procedures, for example, require that you repartition or reformat the disk, which overwrites all existing data.

The hard disk drive capacity in a typical PC has grown far beyond the point at which floppy disks are a viable backup solution. Backup solutions that employ floppy disk drives, such as DOS backup software, are insufficient and too costly for hard disk backups in today's systems. [Table 22.8](#) shows the number of units of various types of media required to back up the 80GB drive in my current notebook/laptop system.

Table 22.8. Amounts and Costs of Various Media Required to Back Up a Full 80GB Drive

Media Type	Number Required	Unit Cost	Net Cost
1.44M floppy disks	54,883	\$0.15	\$8,232
80-minute/700MB CD-R discs	109	\$0.25	\$27
DVD+/-R discs	18	\$1.50	\$27
DAT DDS-4 tapes (native)	4	\$15	\$60
DAT DDS-4 tapes (compressed)	2	\$15	\$30

Assuming the drive were full, it would take 54,883 1.44MB floppy disks, for example, to back up the 80GB hard disk in my current notebook/laptop system! That would cost more than \$8,232 in disks, not to mention the time involved. As you can see, even CD-R would be miserable, requiring 109 discs to back up the entire drive. DVD+/-R, on the other hand, would require only 18 discs, which still wouldn't be much fun but would be adequate in a pinch. Tape, however, really shines here because it would require only two DAT DDS-4 tapes to back up the entire drive, meaning I would have to switch tapes in the drive only once. Although the media cost is a little higher with the tape as compared to CD/DVD, the time savings are enormous. Imagine trying to back up a full 300GB drive in a desktop system that would require 64 DVD+/-R discs but only eight DAT DDS-4 tapes.

One form of backup is magnetic tape. The two main standards are Travan and DAT (digital audio tape). Travan drives are generally slower and hold less than the newest DAT drives, but both are available in relatively competitive versions. The latest Travan tape drives store 20GB/40GB (raw/compressed) on a single tape, whereas DAT DDS-4 drives store 20GB/40GB per tape. These tapes typically cost \$15 or less. If you use larger drives, new versions of DAT and other technologies can be used to back up your drive.

Tape is generally the fastest and safest form of backup, especially considering you can make multiple backups to different tapes, and even move some of the backups offsite in case of theft or fire. Still, the initial cost of the drive has been an impediment to many. The increasing popularity of writable CD-RW drives presents an alternative, although backing up an entire drive requires multiple CDs. In the previous 80GB example, you would need as many as 109 700MB CDs to perform a single backup. Although the media cost is only about \$27, the time involved is still considerable. Recordable DVDs offer 4.7GB of storage per disc, so that would reduce the number of discs needed dramatically, to only 18 in our 80GB example.

Although a tape drive can cost up to \$500 or more, the media costs are really far more significant than the cost of the drive. If you perform responsible backups, you should have at least three sets of media for each system you are backing up. You should use each media set on a rotating basis, and store one of them offsite at all times, in case of fire or theft. You also should introduce new media to the rotation after

approximately a year to prevent excessive wear. If you are backing up multiple systems, these media costs can add up quickly. In addition, you should factor in the cost of your time. If a backup requires manual intervention to change the media during the job, as with any technology except high-capacity tape or external hard drives, I don't recommend it. A backup system should be capable of fitting a complete backup on a single tape or drive so you can schedule the job to run unattended. If someone has to hang around to switch tapes or media every so often, backups become a real chore and are more likely to be overlooked. Also, every time a media change occurs, the likelihood of errors and problems you might not see until you attempt to perform a restore operation substantially increases. Backups are far more important than most people realize, and spending a little more on a quality piece of hardware such as a Travan, DAT, or other high-capacity tape drive will pay off in the long run with greater reliability, lower media costs, higher performance, and unattended backups that contain the entire system file structure. As a second choice for immediate backups, I recommend an external hard drive, although you should still determine how you plan to store the data you want to keep permanently.

With the increasing popularity of removable bulk storage media such as cartridge drives, including Iomega's Zip, and rewritable CDs (CD-RWs), many people are using these devices to perform system backups. In most cases, however, although these drives are excellent for storing backup copies of selected data, they are impractical solutions for regular system backups. This can be due to both the capacity of the media in relation to today's hard disk drives and the cost of the media. You should use multiple sets of media with a CD-RW drive, just as you would with a tape backup.

Although the media for a CD-RW drive are quite inexpensive, it would take several discs to back up a multigigabyte hard drive, adding a measure of inconvenience to the backup process that makes it far less likely to be performed on a regular basis. Rewritable DVD drives can store 4.7GB (uncompressed) on a single DVD, and media costs drop to around \$1.50 per disc in quantities. A rewritable DVD drive has about the same overall media costs for a backup as compared to a CD-RW drive, but reduces the amount of media required considerably. However, it still requires the operator to swap backup media periodically when more than 4.7GB of data must be backed up, and it requires you to use multiple sets of media. Another alternative for backup is to install a second hard drive of equal (or larger) capacity and simply copy from one drive to another. With the low cost of drives these days, this is an economical, fast, and efficient method; however, if a disaster occurs, such as theft or fire, you'll still lose everything. Also, with only one backup, if your backup goes bad when you depend on it, you'll be without any other alternatives. An ATA RAID 1 array automatically mirrors the contents of one drive to another (refer to [Chapter 7](#), "The ATA/IDE Interface," for details); many motherboards now have built-in ATA or SATA RAID adapters.

Because drive capacities have grown significantly in recent years, the best form of backup is often one or more external hard drives. You can perform hard diskbased backups for more than one system with an external hard drive. External hard disks are available in capacities up to 300GB and don't require media swapping. Some models even offer one-button backups. However, you might eventually want to move the data on the external drive over to CD, DVD, or tape media for permanent storage. Hard drive prices have fallen such that backup from drive to drive is often the most economical alternative, given the relative capacity and speed available. In most cases, you should consider using two external drives of equal or larger capacity than your main drive. That way, you can alternate backups to the external drives and move one of them offsite between backups. This provides an extra level of protection and insurance from disaster.

Tip

No matter which backup solution you use, the entire exercise is pointless if you cannot restore your data from the storage medium. You should test your backup system by performing random file restores at regular intervals to ensure the viability of your data.

If your backup supports disaster recovery, be sure to test this feature as well by installing an empty drive and using the disaster recovery feature to rebuild the operating system and

restore the data.

Cleaning a System

One of the most important operations in a good preventive maintenance program is regular and thorough cleaning of the system. Dust buildup on the internal components can lead to several problems. One is that the dust acts as a thermal insulator, which prevents proper system cooling. Excessive heat shortens the life of system components and adds to the thermal stress problem caused by greater temperature changes between the system's power-on and power-off states. Additionally, the dust can contain conductive elements that can cause partial short circuits in a system. Other elements in dust and dirt can accelerate corrosion of electrical contacts, resulting in improper connections. In all, the regular removal of any layer of dust and debris from within a computer system benefits that system in the long run.

Tip

Cigarette smoke contains chemicals that can conduct electricity and cause corrosion of computer parts. The smoke residue can infiltrate the entire system, causing corrosion and contamination of electrical contacts and sensitive components, such as floppy drive read/write heads and optical drive lens assemblies. You should avoid smoking near computer equipment and encourage your company to develop and enforce a similar policy.

Floppy disk drives are particularly vulnerable to the effects of dirt and dust. A floppy drive is essentially a large "hole" in the system case through which air continuously flows. Therefore, these drives accumulate a large amount of dust and chemical buildup within a short time. Hard disk drives, on the other hand, do not present quite the same problem. Because the head disk assembly (HDA) in a hard disk is a sealed unit with a single barometric vent, no dust or dirt can enter without passing through the barometric vent filter. This filter ensures that contaminating dust and particles cannot enter the interior of the HDA. Thus, cleaning a hard disk requires blowing off the dust and dirt from outside the drive. No internal cleaning is required.

Disassembly and Cleaning Tools

Properly cleaning the system and all the boards inside requires certain supplies and tools. In addition to the tools required to disassemble the unit, you should have these items:

- Contact cleaning solution
- Canned air
- A small brush
- Lint-free foam cleaning swabs
- Antistatic wrist-grounding strap

You also might want to acquire these optional items:

- Foam tape
- Low-volatile room-temperature vulcanizing (RTV) sealer
- Silicone-type lubricant
- Computer vacuum cleaner

These simple cleaning tools and chemical solutions enable you to perform most common preventive maintenance tasks.

Chemicals

Chemicals can be used to help clean, troubleshoot, and even repair a system. You can use several types of cleaning solutions with computers and electronic assemblies. Most fall into the following categories:

- Standard cleaners
- Contact cleaner/lubricants
- Dusters

Tip

The makeup of many of the chemicals used for cleaning electronic components has been changing because many of the chemicals originally used are now considered environmentally unsafe. They have been attributed to damaging the earth's ozone layer. Chlorine atoms from chlorofluoro-carbons (CFCs) and chlorinated solvents attach themselves to ozone molecules and destroy them. Many of these chemicals are now strictly regulated by federal and international agencies in an effort to preserve the ozone layer. Most of the companies that produce chemicals used for system cleaning and maintenance have had to introduce environmentally safe replacements. The only drawback is that many of these safer chemicals cost more and usually do not work as well as those they've replaced.

Standard Cleaners

For the most basic function cleaning components, electrical connectors, and contacts one of the most useful chemicals is 1,1,1 trichloroethane. This substance is an effective cleaner that was at one time used to clean electrical contacts and components because it does not damage most plastics and board materials. In fact, trichloroethane is very useful for cleaning stains on the system case and keyboard as well. Unfortunately, trichloroethane is now being regulated as a chlorinated solvent, along with CFCs (chlorofluorocarbons) such as Freon, but electronic chemical-supply companies are offering several replacements.

Alternative cleaning solutions are available in a variety of types and configurations. You can use pure isopropyl alcohol, acetone, trichloroethane, or a variety of other chemicals. Most board manufacturers and service shops are now leaning toward alcohol, acetone, or other chemicals that do not cause ozone depletion and comply with government regulations and environmental safety.

Recently, new biodegradable cleaners described as "citrus-based cleaners" have become popular in the industry, and in many cases are more effective and more economical for circuit board and contact cleaning. These cleaners are commonly known as d-limonene or citrus terpenes and are derived from orange peels, which gives them a strong (but pleasant) citric odor. Another type of terpene is called α -pinene, and is derived from pine trees. You must exercise care when using these cleaners, however, because they can cause swelling of some plastics, especially silicone rubber and PVC.

You should make sure your cleaning solution is designed to clean computers or electronic assemblies. In most cases, this means that the solution should be chemically pure and free from contaminants or other unwanted substances. You should not, for example, use drugstore rubbing alcohol for cleaning electronic

parts or contacts because it is not pure and could contain water or perfumes. The material must be moisture-free and residue-free. The solutions should be in liquid form, not a spray. Sprays can be wasteful, and you almost never spray the solution directly on components. Instead, wet a foam or chamois swab used for wiping the component. These electronic-component cleaning solutions are available at any good electronics parts store.

Contact Cleaner/Lubricants

These chemicals are similar to the standard cleaners but include a lubricating component. The lubricant eases the force required when plugging and unplugging cables and connectors, reducing strain on the devices. The lubricant coating also acts as a conductive protectant that insulates the contacts from corrosion. These chemicals can greatly prolong the life of a system by preventing intermittent contacts in the future.

A unique type of contact enhancer and lubricant called Stabilant 22 is currently on the market. This chemical, which you apply to electrical contacts, greatly enhances the connection and lubricates the contact point; it is much more effective than conventional contact cleaners or lubricants.

Stabilant 22 is a liquid-polymer semiconductor; it behaves like liquid metal and conducts electricity in the presence of an electric current. The substance also fills the air gaps between the mating surfaces of two items that are in contact, making the surface area of the contact larger and also keeping out oxygen and other contaminants that can corrode the contact point.

This chemical is available in several forms. Stabilant 22 is the concentrated version, whereas Stabilant 22a is a version diluted with isopropanol in a 4:1 ratio. An even more diluted 8:1-ratio version is sold in many high-end stereo and audio shops under the name Tweek. Just 15ml of Stabilant 22a sells for about \$40; a liter of the concentrate costs about \$4,000!

As you can plainly see, Stabilant 22 is fairly expensive, but little is required in an application, and nothing else has been found to be as effective in preserving electrical contacts. (NASA uses the chemical on spacecraft electronics.) An application of Stabilant can provide protection for up to 16 years, according to its manufacturer, D.W. Electrochemicals. You will find the company's address and phone number earlier in this chapter and in the Vendor List on the accompanying disc.

Stabilant is especially effective on I/O slot connectors, adapter-card edge and pin connectors, disk drive connectors, power-supply connectors, and virtually any connector in the PC. In addition to enhancing the contact and preventing corrosion, an application of Stabilant lubricates the contacts, making insertion and removal of the connector easier.

Dusters

Compressed gas often is used as an aid in system cleaning. You use the compressed gas as a blower to remove dust and debris from a system or component. Originally, these dusters used CFCs (chlorofluorocarbons) such as Freon, whereas modern dusters use either HFCs (hydrofluorocarbons such as difluoroethane) or carbon dioxide, neither of which is known to damage the ozone layer. Be careful when you use these devices because some of them can generate a static charge when the compressed gas leaves the nozzle of the can. Be sure you are using the type approved for cleaning or dusting off computer equipment, and consider wearing a static grounding strap as a precaution. The type of compressed-air cans used for cleaning camera equipment can sometimes differ from the type used for cleaning static-sensitive computer components.

When using these compressed air products, be sure you hold the can upright so that only gas is ejected from the nozzle. If you tip the can, the raw propellant will come out as a cold liquid, which not only is wasteful but can damage or discolor plastics. You should use compressed gas only on equipment that is powered off, to minimize any chance of damage through short circuits.

Closely related to compressed-air products are chemical-freeze sprays. These sprays are used to quickly cool down a suspected failing component, which often temporarily restores it to normal operation. These substances are not used to repair a device, but to confirm that you have found a failed device. Often, a component's failure is heat-related, and cooling it temporarily restores it to normal operation. If the circuit begins operating normally, the device you are cooling is the suspect device.

Vacuum Cleaners

Some people prefer to use a vacuum cleaner instead of canned gas dusters for cleaning a system. Canned gas is usually better for cleaning in small areas. A vacuum cleaner is more useful when you are cleaning a system loaded with dust and dirt. You can use the vacuum cleaner to suck out the dust and debris instead of simply blowing it around on the other components, which sometimes happens with canned air. For onsite servicing (when you are going to the location of the equipment instead of the equipment coming to you), canned air is easier to carry in a toolkit than a small vacuum cleaner. Tiny vacuum cleaners also are available for system cleaning. These small units are easy to carry and can serve as an alternative to compressed air cans.

Some special vacuum cleaners are specifically designed for use on and around electronic components; they are designed to minimize electrostatic discharge (ESD) while in use. If you are using a regular vacuum cleaner and not one specifically designed with ESD protection, you should take precautions, such as wearing a grounding wrist strap. Also, if the cleaner has a metal nozzle, be careful not to touch it to the circuit boards or components you are cleaning.

Brushes and Swabs

You can use a small makeup, photographic, or paint brush to carefully loosen the accumulated dirt and dust inside a PC before spraying it with canned air or using the vacuum cleaner. Be careful about generating static electricity, however. In most cases, you should not use a brush directly on circuit boards, but only on the case interior and other parts, such as fan blades, air vents, and keyboards. Wear a grounded wrist strap if you are brushing on or near any circuit boards, and brush slowly and lightly to prevent static discharges from occurring.

Use cleaning swabs to wipe off electrical contacts and connectors, floppy or tape drive heads, and other sensitive areas. The swabs should be made of foam or synthetic chamois material that does not leave lint or dust residue. Unfortunately, proper foam or chamois cleaning swabs are more expensive than typical cotton swabs. Do not use cotton swabs because they leave cotton fibers on everything they touch. Cotton fibers are conductive in some situations and can remain on drive heads, which can scratch disks. Foam or chamois swabs can be purchased at most electronics supply stores.

Caution

One item to avoid is an eraser for cleaning contacts. Many people (including me) have recommended using a soft pencil-type eraser for cleaning circuit-board contacts. Testing has proven this to be bad advice for several reasons. One reason is that any such abrasive wiping on electrical contacts generates friction and an ESD. This ESD can be damaging to boards and components, especially the newer low-voltage devices. These devices are especially static

sensitive, and cleaning the contacts without a proper liquid solution is not recommended. Also, the eraser will wear off the gold coating on many contacts, exposing the tin contact underneath, which rapidly corrodes when exposed to air.

Some companies sell premoistened contact cleaning pads soaked in a proper contact cleaner and lubricant. These pads are safe to wipe on conductors and contacts with no likelihood of ESD damage or abrasion of the gold plating.

Silicone Lubricants

You can use a silicone lubricant such as WD-40 to lubricate the door mechanisms on floppy disk drives and any other part of the system that might require clean, nonoily lubrication. Other items you can lubricate are the disk-drivehead slider rails and even printer-head slider rails, to provide smoother operation.

Using silicone instead of conventional oils is important because silicone does not gum up and collect dust and other debris. Always use the silicone sparingly. Do not spray it anywhere near the equipment because it tends to migrate and will end up where it doesn't belong (such as on drive heads). Instead, apply a small amount to a toothpick or foam swab and dab the silicone lubricant on the components where needed. You can use a lint-free cleaning stick soaked in silicone to lubricate the metal print-head rails in a printer.

Obtaining the Required Tools and Accessories

You can obtain most of the cleaning chemicals and tools discussed in this chapter from an electronics supply house, or even your local Radio Shack. A company called Chemtronics specializes in chemicals for the computer and electronics industry. These and other companies that supply tools, chemicals, and other computer and electronic cleaning supplies are listed in the Vendor List on the accompanying disc. With all these items on hand, you should be equipped for most preventive maintenance operations.

Disassembling and Cleaning Procedures

To properly clean your system, you must at least partially disassemble it. Some people go as far as to remove the motherboard. Removing the motherboard results in the best possible access to other areas of the system; but in the interest of saving time, you probably need to disassemble the system only to the point at which the motherboard is completely visible.

To do this, remove all the system's plug-in adapter cards and the disk drives. Complete system disassembly and reassembly procedures are listed in [Chapter 20](#), "Building or Upgrading Systems." Although you can clean the heads of a floppy drive with a cleaning disk without opening the system unit's cover, you probably will want to do more thorough cleaning. In addition to the drive heads, you should clean and lubricate the door mechanism and clean any logic boards and connectors on the drive. This procedure usually requires removing the drive.

Next, do the same thing with the hard disk drives: Clean the logic boards and connectors, and lubricate the grounding strap. To do this, you must remove the hard disk assembly. As a precaution, be sure your data is backed up first.

Reseating Socketed Chips

To learn how to reseat socketed chips, such as the ROM BIOS on some older systems, see the Technical Reference section on the disc packaged with this book.

Cleaning Boards

After reseating any socketed devices that might have crept out of their sockets (see the Technical Reference on the disc for details), the next step is to clean the boards and all connectors in the system. For this step, use the cleaning solutions and the lint-free swabs mentioned earlier.

First, clean the dust and debris off the board and then clean any connectors on the board. To clean the boards, using a vacuum cleaner designed for electronic assemblies and circuit boards or a duster can of compressed gas is usually best. The dusters are especially effective at blasting any dust and dirt off the boards.

Also, blow any dust out of the power supply, especially around the fan intake and exhaust areas. You do not need to disassemble the power supply to do this; simply use a duster can and blast the compressed air into the supply through the fan exhaust port. This will blow the dust out of the supply and clean off the fan blades and grill, which will help with system airflow.

Caution

Be careful with ESD, which can cause damage when you are cleaning electronic components. Take extra precautions in the dead of winter or in extremely dry, high-static environments. You can apply antistatic sprays and treatments to the work area to reduce the likelihood of ESD damage.

An antistatic wrist-grounding strap is recommended (refer to [Figure 22.6](#) earlier in this chapter). This should be connected to a ground on the card or board you are wiping. This strap ensures that no electrical discharge occurs between you and the board. An alternative method is to keep a finger or thumb on the ground of the motherboard or card as you wipe it off.

Cleaning Connectors and Contacts

Cleaning the connectors and contacts in a system promotes reliable connections between devices. On a motherboard, you should clean the slot connectors, power supply connectors, keyboard and mouse connectors, and speaker connector. For most plug-in cards, you should clean the edge connectors that plug in to slots on the motherboard and any other connectors, such as external ones mounted on the card bracket.

Submerge the lint-free swabs in the liquid cleaning solution. If you are using the spray, hold the swab away from the system and spray a small amount on the foam end until the solution starts to drip. Then, use the soaked foam swab to wipe the connectors on the boards. Presoaked wipes are the easiest to use; simply wipe them along the contacts to remove any accumulated dirt and leave a protective coating behind.

On the motherboard, pay special attention to the slot connectors. Be liberal with the liquid; resoak the foam swab repeatedly, and vigorously clean the connectors. Don't worry if some of the liquid drips on the surface of the motherboard. These solutions are entirely safe for the whole board and will not damage the

components.

Use the solution to wash the dirt off the gold contacts in the slot connectors, and then clean any other connectors on the board. Clean the keyboard and mouse connectors, the grounding positions where screws ground the board to the system chassis, the power-supply connectors, the speaker connectors, and the battery connectors.

If you are cleaning a plug-in board, pay special attention to the edge connector that mates with the slot connector on the motherboard. When people handle plug-in cards, they often touch the gold contacts on these connectors. Touching the gold contacts coats them with oils and debris, which prevents proper contact with the slot connector when the board is installed. Make sure these gold contacts are free of all finger oils and residue. It is a good idea to use one of the contact cleaners that has a conductive lubricant, which makes it easier to push the adapter into the slot and also protects the contacts from corrosion.

You also should use the swab and solution to clean the ends of ribbon cables or other types of cables or connectors in a system. Clean the floppy drive cables and connectors, the hard disk cables and connectors, and any others you find. Don't forget to clean the edge connectors that are on the disk drive logic boards, as well as the power connectors to the drives.

Cleaning the Keyboard and Mouse

Keyboards and mice are notorious for picking up dirt and garbage. If you ever open up an older keyboard, you will be amazed at the junk you find in there.

To prevent problems, you should periodically clean the keyboard with a vacuum cleaner. An alternative method is to turn the keyboard upside down and shoot it with a can of compressed air. This blows out the dirt and debris that has accumulated inside the keyboard and possibly prevents future problems with sticking keys or dirty keyswitches.

If a particular key is stuck or making intermittent contact, you can soak or spray that switch with contact cleaner. The best way to do this is to first remove the keycap and then spray the cleaner into the switch. This usually does not require complete disassembly of the keyboard. Periodic vacuuming or compressed gas cleaning prevents more serious problems with sticking keys and keyswitches.

Most mice are easy to clean. In most cases, a twist-off locking retainer keeps the mouse ball retained in the body of the mouse. By removing the retainer, the ball drops out. After removing the ball, you should clean it with one of the electronic cleaners. I recommend a pure cleaner instead of a contact cleaner with lubricant because you do not want any lubricant on the mouse ball. Then, wipe off the rollers in the body of the mouse with the cleaner and some swabs.

Monthly cleaning of a mouse in this manner eliminates or prevents skipping or erratic movement. I also recommend a mouse pad for most ball-type mice because the pad prevents the mouse ball from picking up debris from your desk.

Other pointing devices requiring little or no maintenance are the IBM-designed TrackPoint and similar systems introduced by other manufacturers, such as the Glidepoint by Alps. These devices are totally sealed and use pressure transducers to control pointer movement. Optical mice that don't use a ball or roller mechanism also require little or no maintenance. Because they are sealed, cleaning need only be performed externally and is as simple as wiping off the device with a mild cleaning solution to remove oils and other deposits that have accumulated from handling them.

Hard Disk Maintenance

Certain preventive maintenance procedures protect your data and ensure that your hard disk works efficiently. Some of these procedures actually minimize wear and tear on your drive, which prolongs its life. Additionally, a high level of data protection can be implemented by performing some simple commands periodically. These commands provide methods for backing up (and possibly later restoring) critical areas of the hard disk that, if damaged, would disable access to all your files.

Defragmenting Files

Over time, as you delete and save files to a hard disk, the files become fragmented. This means they are split into many noncontiguous areas on the disk. One of the best ways to protect both your hard disk and the data on it is to periodically defragment the files on the disk. This serves two purposes. One is that by ensuring that all the files are stored in contiguous sectors on the disk, head movement and drive wear and tear is minimized. This has the added benefit of improving the speed at which the drive retrieves files by reducing the head thrashing that occurs every time it accesses a fragmented file.

The second major benefit, and in my estimation the more important of the two, is that in the case of a disaster in which the file system is severely damaged, the data on the drive can usually be recovered if the files are contiguous. On the other hand, if the files are split up in many pieces across the drive, figuring out which pieces belong to which files is virtually impossible without an intact file system. For the purposes of data integrity and protection, I recommend defragmenting your hard disk drives on a monthly basis.

The three main functions in most defragmentation programs are as follows:

- File defragmentation
- File packing (free space consolidation)
- File sorting

Defragmentation is the basic function, but most other programs also add file packing. Packing the files is optional on some programs because it usually takes additional time to perform. This function packs the files at the beginning of the disk so all free space is consolidated at the end of the disk. This feature minimizes future file fragmentation by eliminating any empty holes on the disk. Because all free space is consolidated into one large area, any new files written to the disk are capable of being written in a contiguous manner with no fragmentation.

The last function, file sorting (sometimes called disk optimizing), is not usually necessary and is performed as an option by many defragmenting programs. This function adds a tremendous amount of time to the operation and has little or no effect on the speed at which information is accessed. It can be somewhat beneficial for disaster recovery purposes because you will have an idea of which files came before or after other files if a disaster occurs. Not all defragmenting programs offer file sorting, and the extra time it takes is probably not worth any benefits you will receive. Other programs can sort the order that files are listed in directories, which is a quick and easy operation compared to sorting the file ordering the disk.

Windows 9x/Me/2000/XP include a disk defragmentation program with the operating system, which you can use on any file system the OS supports. For older DOS, Windows 3.x, and some versions of NT, you must purchase a third-party defragmentation program. Norton Utilities includes a disk defragmenter, as do many other utility packages. If you elect to use a third-party product on a Windows 9x/Me/2000/XP system, be certain that it supports the file system you use on your drives. Running a FAT16 defragmentation program on a FAT32 drive can cause severe problems. An excellent third-party defrag program that works on all systems is VOPT by Golden Bow. See the Vendor List on the accompanying disc for more information on these programs.

Before you defragment your disks, you should run a disk repair program, such as ScanDisk or Norton Disk Doctor, even if you are not experiencing any problems. This ensures that your drives are in good working order before you begin the defragmentation process.

Windows Maintenance Wizard

Windows 98 and above include a Task Scheduler program that enables you to schedule programs for automatic execution at specified times. The Maintenance Wizard walks you through the steps of scheduling regular disk defragmentations, disk error scans, and deletions of unnecessary files. You can schedule these processes to execute during nonworking hours, so regular system activities are not disturbed.

Virus and Spyware Checking

Viruses and spyware are dangers to any system, and making scans with antivirus and antispyware utilities a regular part of your preventive maintenance program is a good idea. Many aftermarket utility packages are available that scan for and remove viruses and spyware. No matter which of these programs you use, you should perform a scan periodically, especially before making hard disk backups. This helps ensure that you catch any potential problem before it becomes a major catastrophe. In addition, selecting antivirus and antispyware products from vendors that provide regular updates is important. The updates include signatures that determine which virus or spyware programs the software can detect and cure, and because new virus and spyware programs are constantly being introduced, these updates are essential.

Tip

Because viruses and especially spyware are more dangerous and numerous than ever, turn on the firewall feature in your operating system and enable the automatic update feature found in most recent programs to keep your protection up to date. Even with a dialup connection, it takes only a few minutes a day to get downloads. If you have a broadband connection, the latest protection is downloaded in just a few moments. Using the firewall will help prevent many types of virus and other software exploits from attacking your system.

Passive Preventive Maintenance Procedures

Passive preventive maintenance involves taking care of the system by providing the best possible environment both physical and electrical for the system. Physical concerns are conditions such as ambient temperature, thermal stress from power cycling, dust and smoke contamination, and disturbances such as shock and vibration. Electrical concerns are items such as ESD, power-line noise, and radio-frequency interference. Each of these environmental concerns is discussed in the following sections.

Examining the Operating Environment

Oddly enough, one of the most overlooked aspects of microcomputer preventive maintenance is protecting the hardware and the sizable financial investment it represents from environmental abuse. Computers are relatively forgiving, and they are generally safe in an environment that is comfortable for people. Computers, however, are often treated with no more respect than desktop calculators. The result of this type of abuse is many system failures.

Before you set up a new PC, prepare a proper location for it that is free of airborne contaminants such as smoke or other pollution. Do not place your system in front of a window; the computer should not be exposed to direct sunlight or temperature variations. The environmental temperature should be as constant as possible. Power should be provided through properly grounded outlets and should be stable and free from electrical noise and interference. Keep your system away from radio transmitters or other sources of radio frequency energy.

Note

I also don't recommend using computer desks that place the system unit in a sealed cabinet; this is a good way to promote overheating.

Heating and Cooling

Thermal expansion and contraction from ambient temperature changes place stress on a computer system. Therefore, keeping the temperature in your office or room relatively constant is important to the successful operation of your computer system.

Temperature variations can lead to serious problems. You might encounter excessive chip creep, for example. If extreme variations occur over a short period, signal traces on circuit boards can crack and separate, solder joints can break, and contacts in the system can undergo accelerated corrosion. Solid-state components such as chips can be damaged also, and a host of other problems can develop.

Temperature variations can wreak havoc with hard disk drives, too. On some drives, writing to a disk at different ambient temperatures can cause data to be written at different locations relative to the track centers. This can cause read and write problems at a later time.

To ensure that your system operates in the correct ambient temperature, you must first determine your system's specified functional range. Most manufacturers provide data about the correct operating temperature range for their systems. Two temperature specifications might be available, one indicating allowable temperatures during operation and another indicating allowable temperatures under nonoperating conditions. IBM, for example, indicates the following temperature ranges as acceptable for most of its systems:

System on: 60°-90° Fahrenheit

System off: 50°-110° Fahrenheit

For the safety of the disk and the data it contains, avoid rapid changes in ambient temperatures. If rapid temperature changes occur—for example, when a new drive is shipped to a location during the winter and then brought indoors—let the drive acclimate to room temperature before turning it on. In extreme cases, condensation can form on the platters inside the drive head-disk assembly (HDA), which is disastrous for

the drive if you turn it on before the condensation has a chance to evaporate. Most drive manufacturers specify a timetable to use as a guide in acclimating a drive to room temperature before operating it. You usually must wait several hours to a day before a drive is ready to use after it has been shipped or stored in a cold environment. Manufacturers normally advise that you leave the drive in its packing until it is acclimated. Removing the drive from a shipping carton when extremely cold increases the likelihood of condensation forming as the drive warms up.

Most office environments provide a stable temperature in which to operate a computer system, but some do not. Be sure to give some consideration to the placement of your equipment.

Power Cycling (On/Off)

As you have just learned, the temperature variations a system encounters greatly stress the system's physical components. The largest temperature variations a system encounters, however, are those that occur during the warm-up period right after you turn on the computer. Powering on a cold system subjects it to the greatest possible internal temperature variations. If you want a system to have the longest and most trouble-free life possible, you should limit the temperature variations in its environment. You can limit the extreme temperature cycling in two simple ways during a cold startup: Leave the system off all the time or leave it on all the time. Of these two possibilities, of course, you probably will want to choose the latter option. Leaving the power on is the best way I know to promote system reliability. If your only concern is system longevity, the simple recommendation is to keep the system unit powered on (or off!) continuously. In the real world, however, there are more variables to consider, such as the cost of electricity, the potential fire hazard of unattended running equipment, and other concerns, as well.

If you think about the way light bulbs typically fail, you can begin to understand how thermal cycling can be dangerous. Light bulbs burn out most often when you first turn them on because the filament must endure incredible thermal stress as it changes temperature, in less than one second, from ambient to several thousands of degrees. A bulb that remains on continuously lasts longer than one that is turned on and off repeatedly.

The place where problems are most likely to occur immediately at power-on is in the power supply. The startup current draw for the system during the first few seconds of operation is very high compared to the normal operating-current draw. Because the current must come from the power supply, the supply has an extremely demanding load to carry for the first few seconds of operation, especially if several disk drives must be started. Motors have an extremely high power-on current draw. This demand often overloads a marginal circuit or component in the supply and causes it to burn or break with a "snap." I have seen several power supplies die the instant a system was powered up. To enable your equipment to have the longest possible life, try to keep the temperature of solid-state components relatively constant, and limit the number of startups on the power supply. The only way I know to do this is to leave the system on.

Although it sounds like I am telling you to leave all your computer equipment on 24 hours a day, 7 days a week, I no longer recommend this type of operation. A couple of concerns have tempered my urge to leave everything running continuously. One is that an unattended system that is powered on represents a fire hazard. I have seen monitors catch fire after internally shorting and systems whose cooling fans have frozen, causing the power supply and the entire system to overheat. I do not leave any system running in an unattended building. Another problem is wasted electrical power. Many companies have adopted austerity programs that involve turning off lights and other items when not in use. The power consumption of some of today's high-powered systems and accessories is not trivial. Also, an unattended operating system is more of a security risk than one that is powered off and locked.

Realitiessuch as the fire hazard of unattended systems running during night or weekend hours, security problems, and power-consumption issuesmight prevent you from leaving your system on all the time. Therefore, you must compromise. Power on the system only one time daily. Don't power the system on and

off several times every day. This good advice is often ignored, especially when several users share systems. Each user powers on the system to perform work on the PC and then powers off the system. These systems tend to have many more problems with component failures.

If you are in a building with a programmable thermostat, you have another reason to be concerned about temperatures and disk drives. Some buildings have thermostats programmed to turn off the heat overnight or over the weekend. These thermostats are programmed also to quickly raise the temperature just before business hours every day. In Chicago, for example, outside temperatures in the winter can dip to 20° (excluding the windchill factor). An office building's interior temperature can drop to as low as 50° during the weekend. When you arrive Monday morning, the heat has been on for only an hour or so, but the hard disk platters might not yet have reached even 60° when you turn on the system. During the first 20 minutes of operation, the disk platters rapidly rise in temperature to 120° or more. If you still have an inexpensive stepper motor hard disk and begin writing to the disk at these low temperatures, you are setting yourself up for trouble.

Tip

If you do not leave a system on continuously, at least give it 15 minutes or more to warm up after a cold start before writing to the hard disk. This practice does wonders for the reliability of the data on your disk.

If you do leave your system on for long periods of time, make sure the screen is blank or displays a random image if the system is not in use. The phosphor on the picture tube can burn if a stationary image is left onscreen continuously. Higher-persistence phosphor monochrome screens are most susceptible, and the color displays with low-persistence phosphors are the least susceptible. Most of the monitors used with today's PCs will not show the effect of a screen burn. If you ever have seen a monochrome display with the image of some program permanently burned in even with the display off you know what I mean. Look at the monitors that display flight information at the airport; they usually show some of the effects of phosphor burn.

Most modern displays that have power-saving features can automatically enter a standby mode on command by the system. If your system has these power-saving functions, enable them because they help reduce energy costs and preserve the monitor.

Static Electricity

Static electricity or electrostatic discharge (ESD) can cause numerous problems within a system. The problems usually appear during the winter months when humidity is low or in extremely dry climates where the humidity is low year-round. In these cases, you might need to take special precautions to ensure that your PC is not damaged. Refer to [Chapter 19](#), "Power Supplies," and [Chapter 20](#) for more information on ESD.

Static discharges outside a system-unit chassis are rarely a source of permanent problems within the system. Usually, the worst possible effect of a static discharge to the case, keyboard, or even a location near the computer is a parity check (memory) error or a system lockup. In some cases, I have been able to cause parity checks or system lockups by simply walking past a PC. Most static-sensitivity problems are caused by improper grounding of the system power. Be sure you always use a three-prong, grounded power cord plugged in to a properly grounded outlet. If you are unsure about the outlet, you can buy an outlet tester, such as those described earlier in this chapter, at most electronics supply or hardware stores

for only a few dollars.

Whenever you open a system unit or handle circuits removed from the system, you must be much more careful with static. You can permanently damage a component with a static discharge if the charge is not routed to a ground. I usually recommend handling boards and adapters first by a grounding point such as the bracket to minimize the potential for static damage.

An easy way to prevent static problems is with good power-line grounding, which is extremely important for computer equipment. A poorly designed power-line grounding system is one of the primary causes of poor computer design. The best way to prevent static damage is to prevent the static charge from getting into the computer in the first place. The chassis ground in a properly designed system serves as a static guard for the computer and redirects the static charge safely to the ground. For this ground to be complete, therefore, the system must be plugged in to a properly grounded three-wire outlet.

If the static problem is extreme, you can resort to other measures. One is to use a grounded static mat underneath the computer. Touch the mat first before you touch the computer to ensure that any static charges are routed to ground and away from the system unit's internal parts. If problems still persist, you might want to check out the building's electrical ground. I have seen installations that had three-wire outlets that were rendered useless by the building's ungrounded electrical service.

Power-Line Noise

To run properly, a computer system requires a steady supply of clean, noise-free power. In some installations, however, the power line serving the computer also serves heavy equipment, and the voltage variations resulting from the on/off cycling of this equipment can cause problems for the computer. Certain types of equipment on the same power line also can cause voltage spikes—short, transient signals of sometimes 1,000V or more—that can physically damage a computer. Although these spikes are rare, they can be crippling. Even a dedicated electrical circuit used by only a single computer can experience spikes and transients, depending on the quality of the power supplied to the building or circuit.

During the site-preparation phase of a system installation, you should be aware of these factors to ensure a steady supply of clean power:

- If possible, the computer system should be on its own circuit with its own circuit breaker. This setup does not guarantee freedom from interference, but it helps.
- The circuit should be checked for a good, low-resistance ground, proper line voltage, freedom from interference, and freedom from brownouts (voltage dips).
- A three-wire circuit is a must, but some people substitute grounding-plug adapters to adapt a grounded plug to a two-wire socket. This setup is not recommended; the ground is there for a reason.
- Power-line noise problems increase with the resistance of the circuit, which is a function of wire size and length. So, to decrease resistance, avoid extension cords unless absolutely necessary, and then use only heavy-duty extension cords.
- Inevitably, you will want to plug in other equipment later. Plan ahead to avoid the temptation to connect too many items to a single outlet. If possible, provide a separate power circuit for noncomputer-related devices.

Air conditioners, coffee makers, copy machines, laser printers, space heaters, vacuum cleaners, and power tools are some of the worst corrupters of a PC system's power. Any of these items can draw an excessive amount of current and wreak havoc with a PC system on the same electrical circuit. I've seen offices in which all the computers begin to crash at about 9:05 a.m. daily, which is when all the coffee makers are turned on!

Also, try to ensure that copy machines and laser printers do not share a circuit with other computer equipment. These devices draw a large amount of power.

Another major problem in some companies is partitioned offices. Many of these partitions are prewired with their own electrical outlets and are plugged in to one another in a sort of power-line daisy-chain, similar to chaining power strips together. I pity the person in the cubicle at the end of the electrical daisy-chain, who is likely to have very erratic power!

As a real-world example of too many devices sharing a single circuit, I can describe several instances in which a personal computer had a repeating parity check problem. All efforts to repair the system had been unsuccessful. The reported error locations from the parity-check message were inconsistent, which normally indicates a problem with power. The problem could have been the power supply in the system unit or the external power supplied from the wall outlet. This problem was solved one day as I stood watching the system. The parity check message was displayed at the same instant that someone two cubicles away turned on a copy machine. Placing the computers on a separate line solved the problem.

By following the guidelines in this section, you can create the proper power environment for your systems and help ensure trouble-free operation.

Radio-Frequency Interference

Radio-frequency interference (RFI) is easily overlooked as a problem factor. The interference is caused by any source of radio transmissions near a computer system. Living next door to a 50,000-watt commercial radio station is one sure way to get RFI problems, but less-powerful transmitters can cause problems, too. I know of many instances in which cordless telephones have caused sporadic random keystrokes to appear, as though an invisible entity were typing on the keyboard. I also have seen RFI cause a system to lock up. Solutions to RFI problems are more difficult to state because every case must be handled differently. Sometimes, simply moving the system eliminates the problem because radio signals can be directional in nature. At other times, you must invest in specially shielded cables for external devices, such as the keyboard and the monitor. If the keyboard or mouse is wireless, RFI can be especially problematic; the only solution might be to try a different brand or model that operates on a different frequency.

One type of solution to an RFI noise problem with cables is to pass the cable through a toroidal iron core, a doughnut-shaped piece of iron placed around a cable to suppress both the reception and transmission of electromagnetic interference (EMI). Many monitors include a toroid (sometimes spelled *torroid*) on the cable that connects to the computer. If you can isolate an RFI noise problem in a particular cable, you often can solve the problem by passing the cable through a toroidal core. Because the cable must pass through the center hole of the core, it often is difficult, if not impossible, to add a toroid to a cable that already has end connectors installed.

Radio Shack sells a special snap-together toroid designed specifically to be added to cables already in use. This toroid looks like a thick-walled tube that has been sliced in half. You simply lay the cable in the center of one of the halves, and snap the other half over the first. This type of construction makes adding the noise-suppression features of a toroid to virtually any existing cable easy.

Tip

For a comprehensive selection of electronics parts, tools, and other supplies, I recommend the following sources:

- Allied Electronics (www.alliedelec.com)
- Digi-Key (www.digi-key.com)
- Mouser Electronics (www.mouser.com)
- Newark InOne (www.newark.com)
- Radio Shack (www.radioshack.com)

For tools only, I also recommend

- Jensen Tools (www.jensentools.com)

Most of these companies also have comprehensive paper catalogs, which can often make it easier to do general browsing and find what you need.

The best, if not the easiest, way to eliminate an RFI problem is to correct it at the source. It is unlikely that you'll be able to convince the commercial radio station near your office to shut down, but if you are dealing with a small radio transmitter that is generating RFI, sometimes you can add a filter to the transmitter that suppresses spurious emissions. Unfortunately, problems sometimes persist until the transmitter is either switched off or moved some distance away from the affected computer.

Dust and Pollutants

Dirt, smoke, dust, and other pollutants are bad for your system. The power-supply fan carries airborne particles through your system, and they collect inside. If your system is used in an extremely harsh environment, you might want to investigate some of the industrial systems on the market designed for harsh conditions.

Many companies make special hardened versions of their systems for harsh environments. Industrial systems typically use a different cooling system from the one used in regular PCs. A large cooling fan is used to pressurize the case rather than depressurize it. The air pumped into the case passes through a filter unit that must be cleaned and changed periodically. The system is pressurized so that no contaminated air can flow into it; air flows only outward. The only way air can enter is through the fan and filter system.

These systems also might have special keyboards impervious to liquids and dirt. Some flat-membrane keyboards are difficult to type on, but are extremely rugged; others resemble the standard types of keyboards but have a thin, plastic membrane that covers all the keys. You can add this membrane to normal types of keyboards to seal them from the environment.

A relatively new breed of humidifier can cause problems with computer equipment. This type of humidifier uses ultrasonics to generate a mist of water sprayed into the air. The extra humidity helps cure problems with static electricity resulting from a dry climate, but the airborne water contaminants can cause many problems. If you use one of these systems, you might notice a white, ash-like deposit forming on components. The deposit is the result of abrasive and corrosive minerals suspended in the vaporized water. If these deposits collect on the system components, they can cause all kinds of problems. The only safe way to run one of these ultrasonic humidifiers is to use distilled water. If you use a humidifier, be sure it does not generate these deposits.

If you do your best to keep the environment for your computer equipment clean, your system will run

better and last longer. Also, you will not have to open up your unit as often for complete preventive maintenance cleaning.

Troubleshooting Tips and Techniques

Troubleshooting PC hardware problems can seem daunting to the uninitiated, but in reality it is much simpler than it seems. Most problems can be diagnosed and corrected using few, if any, special tools and can be accomplished by anybody who can apply simple deductive reasoning and logical thinking. PCs have become more complicated and yet simpler all at the same time. More and more complex internal circuits mean that there are potentially more things that can go wrong more ways the system can fail. On the other hand, today's complex circuits are embedded into fewer boards, with fewer chips on each board and more serial interconnections using fewer pins (fewer wires). The internal consolidation means that isolating which replaceable component has failed is in many ways simpler than ever before. An understanding of the basics of how PCs work, combined with some very simple tools, some basic troubleshooting tips, and logical thinking and common sense, will enable you to effectively diagnose and repair your own systems, saving a tremendous amount of money over taking it to a shop. In some cases, you can save enough money to practically pay for an entire new system. The bottom line with troubleshooting PC problems is that a solution exists for every problem, and through simple practices combined with deductive reasoning, that solution can easily be found.

Note

This section lists basic and general system troubleshooting procedures and guidelines. For specific procedures for troubleshooting a component in the system, use [Appendix C](#), "Troubleshooting Index," as a quick reference for finding the chapter or section dedicated to that part of the PC.

Modern PCs More Complicated and More Reliable

Consider this: The modern PC is an incredible collection of hardware and software. Focusing specifically on the hardware, between 50 and more than 400 million transistors exist in modern processors. In addition, nearly 8.6 billion transistors are in 1GB of RAM; hundreds of millions of transistors exist in the motherboard chipset, video processor, and video RAM; and millions more are in the other adapter cards or logic boards in the system. Each of these billions of interconnected transistors must not only function properly, but also operate in an orderly fashion within strictly enforced timing windows, some of which are measured in picoseconds (trillionths of a second). When you realize that your PC will lock up or crash if any one of these transistors fails to operate properly and on time and/or any one of the billions of circuit paths and interconnections between the transistors or devices containing them fails in any way it is a wonder that PCs work at all!

Every time I turn on one of my systems and watch it boot up, I think about the billions upon billions of components and trillions upon trillions of machine/program steps and sequences that have to function properly to get there. As you can now see, many opportunities exist for problems to arise.

Although modern PCs are exponentially more complicated than their predecessors, from another point of view they have become simpler and more reliable. When you consider the complexity of the modern PC, it is not surprising that problems occasionally do arise. However, modern design and manufacturing techniques have made PCs more reliable and easier to service despite their ever-increasing internal complexity. Today's systems have fewer and fewer replaceable components and individual parts, which is a bit of a paradox. The truth is that, as PCs have become more complex, they have also become simpler and

easier to service in many ways.

Industry-Standard Replaceable Components

The use of industry-standard components is one of the key features of a PC. This means that virtually all the parts that make up a system are interchangeable with other systems in some manner. This also means that the parts are plentiful, inexpensive, and generally very easy to install. A typical PC contains the following replaceable components, most of which are made to industry standards for design and form factor:

- Motherboard
- Processor
- CPU heatsink/fan
- RAM
- CMOS battery
- Chassis with optional fan
- Power supply
- Video card^[*]

^[*] *May be integrated into the motherboard in some systems.*

- Monitor
- Sound card^[*]
- Speakers
- Network card^[*]
- Hard drive
- CD-ROM/RW drive
- DVD-ROM/+RW drive
- Floppy drive
- Drive cables
- Keyboard
- Mouse

Although some of the more well-optioned systems might have even more components than listed here, you can see that most PCs have fewer than 20 replaceable "parts." Some can have as few as 1015, depending on how many options are present and how they are integrated. From a hardware troubleshooting or repair perspective, one of these components is either improperly installed (configured) or defective. If it's improperly installed or configured, the component can be repaired by merely reinstalling it or configuring it properly. If it's truly defective, the component must simply be replaced. When a PC is broken down to the basic replaceable parts, you can see that it really isn't that complicated, which is why I've spent my career helping people to easily perform their own repairs or upgrades and even build entire systems from scratch.

Reinstall or Replace?

When dealing with hardware problems, the first simple truth to understand is that you do not usually *repair* anything you *reinstall* or *replace* it instead. You reinstall because the majority of PC hardware problems are caused by a particular component being improperly installed or configured. I remember hearing from IBM many years ago that it had found that 60% or more of the problems handled by its service technicians were due to improper installation or configuration, meaning the hardware was not actually defective. This was, in fact, the major impetus behind the plug-and-play revolution, which has eliminated the need to manually configure jumpers and switches on most hardware devices. This has thus minimized the expertise

necessary to install hardware properly and has also minimized installation, configuration, and resource conflict problems. Still, plug and play has sometimes been called *plug and pray* because it does not always work perfectly, sometimes requiring manual intervention to make it work properly.

You replace because of the economics of the situation with computer hardware. The bottom line is that it financially is much cheaper to replace a failed circuit board with a new one than to repair it. For example, you can purchase a new, state-of-the-art motherboard for around \$100, but repairing an existing board normally costs much more than that. Modern boards use surface-mounted chips that have pin spacings measured in hundredths of an inch, requiring sophisticated and expensive equipment to attach and solder the chip. Even if you could figure out which chip had failed and had the equipment to replace it, the chips themselves are usually sold in quantities of thousands and obsolete chips are usually not available. The net effect of all of this is that the replacable components in your PC have become disposable technology. Even a component as large and comprehensive as the motherboard is replaced rather than repaired.

Troubleshooting by Replacing Parts

You can troubleshoot a PC in several ways, but in the end it often comes down to simply reinstalling or replacing parts. That is why I normally use a simple "known-good spare" technique that requires very little in the way of special tools or sophisticated diagnostics. In its simplest form, say you have two identical PCs sitting side by side. One of them has a hardware problem; in this example let's say the memory module (DIMM) is defective. Depending on how and where the defect lies, this could manifest itself in symptoms ranging from a completely dead system to one that boots up normally but crashes when running Windows or software applications. You observe that the system on the left has the problem but the system on the right works perfectly; they are otherwise identical. The simplest technique for finding the problem would be to swap parts from one system to another, one at a time, retesting after each swap. At the point when the DIMMs were swapped, upon powering up and testing (in this case testing is nothing more than allowing the system to boot up and run some of the installed applications), the problem has now moved from one system to the other. Knowing that the last item swapped over was the DIMM, you have just identified the source of the problem! This did not require an expensive (\$2,000 or more) DIMM test machine or any diagnostics software. Because components such as DIMMs are not economical to repair, replacing the defective DIMM would be the final solution.

Although this is very simplistic, it is often the quickest and easiest way to identify a problem component as opposed to specifically testing each item with diagnostics. Instead of having an identical system standing by to borrow parts from, most technicians have an inventory of what they call "known-good spare" parts. These are parts that have been previously used, are known to be functional, and can be used to replace a suspicious part in a problem machine. However, this is different from new replacement parts because, when you open a box containing a new component, you really can't be 100% sure that it works. I've been in situations in which I've had a defective component and replaced it with another (unknown to me) defective *new* component and the problem remained. Not knowing that the new part I just installed was also defective, I wasted a lot of time checking other parts that were not the problem. This technique is also effective because so few parts are needed to make up a PC and the known-good parts don't always have to be the same (for example, a lower-end video card can be substituted in a system to verify that the original card had failed).

Troubleshooting by the Bootstrap Approach

Another variation on this theme is the "bootstrap approach," which is especially good for what seems to be a dead system. In this approach, you take the system apart to strip it down to the bare minimum necessary, functional components and test it to see whether it works. For example, you might strip down a system to the chassis/power supply, bare motherboard, CPU (with heatsink), one bank of RAM, and a video card with display and then power it up to see whether it works. In that stripped configuration, you should see the POST or splash (logo) screen on the display, verifying that the motherboard, CPU, RAM, video card,

and display are functional. If a keyboard is connected, you should see the three LEDs (capslock, scrlock, and numlock) flash within a few seconds after powering on. This indicates that the CPU and motherboard are functioning because the POST routines are testing the keyboard. After you get the system to a minimum of components that are functional, you should reinstall or add one part at a time, testing the system each time you make a change to verify it still works and that the part you added or changed is not the cause of a problem. Essentially, you are rebuilding the system from scratch using the existing parts, but doing it one step at a time.

Many times problems are caused by corrosion on contacts or connectors, so the mere act of disassembling and reassembling a PC will "magically" repair it. Over the years, I've disassembled, tested, and reassembled many systems only to find no problems after the reassembly. How can merely taking it apart and reassembling repair a problem? Although it might seem that nothing was changed and everything is installed exactly like it was before, in reality simply unplugging and replugging renews all the slot and cable connections between devices, which is often all the system needs. Some useful troubleshooting tips include

- Eliminate unnecessary variables or components that are not pertinent to the problem.
- Reinstall, reconfigure, or replace only one component at a time.
- Test after each change you make.
- Keep a detailed record (write it down) of each step you take.
- Don't give up! Every problem has a solution.
- If you hit a roadblock, take a break or work on another problem. A fresh approach the next day often reveals things you overlooked.
- Don't overlook the simple or obvious. Double- and triple-check the installation and configuration of each component.
- Keep in mind that the power supply is one of the most failure-prone parts in a PC, as well as one of the most overlooked components. A high-output "known-good" spare power supply is highly recommended to use for testing suspect systems.
- Cables and connections are also a major cause of problems, so keep replacements of all types on hand.

Before starting any system troubleshooting, a few basic steps should be performed to ensure a consistent starting point and to enable isolating the failed component:

1.

Turn off the system and any peripheral devices. Disconnect all external peripherals from the system, except for the keyboard and video display.

2.

Make sure the system is plugged in to a properly grounded power outlet.

3.

Make sure the keyboard and video displays are connected to the system. Turn on the video display, and turn up the brightness and contrast controls to at least two-thirds of the maximum. Some displays have onscreen controls that might not be intuitive. Consult the display documentation for more information on how to adjust these settings. If you can't get any video display but the system seems to be working, try moving the card to a different slot (not possible with AGP or PCI Express video adapters) or try a different video card or monitor.

To enable the system to boot from a hard disk, make sure no floppy disk is in the floppy drive. Or put a known-good bootable floppy with DOS or diagnostics on it in the floppy drive for testing.

5.

Turn on the system. Observe the power supply, chassis fans (if any), and lights on either the system front panel or power supply. If the fans don't spin and the lights don't light, the power supply or motherboard might be defective.

6.

Observe the power on self test (POST). If no errors are detected, the system beeps once and boots up. Errors that display onscreen (*nonfatal* errors) and that do not lock up the system display a text message that varies according to BIOS type and version. Record any errors that occur and refer to the disc accompanying this book for a list of BIOS error codes for more information on any specific codes you see. Errors that lock up the system (*fatal* errors) are indicated by a series of audible beeps. Refer to the disc for a list of beep error codes.

7.

Confirm that the operating system loads successfully.

Note

The Technical Reference section of the disc accompanying this book contains an exhaustive listing of BIOS error codes, error messages, and beep codes for BIOSs from Phoenix, AMI, Award, Microid Research, and IBM.

Problems During the POST

Problems that occur during the POST are usually caused by incorrect hardware configuration or installation. Actual hardware failure is a far less-frequent cause. If you have a POST error, check the following:

1.

Are all cables correctly connected and secured?

2.

Are the configuration settings correct in Setup for the devices you have installed? In particular, ensure the processor, memory, and hard drive settings are correct.

3.

Are all drivers properly installed?

4.

Are switches and jumpers on the baseboard correct, if changed from the default settings?

5.

Are all resource settings on add-in boards and peripheral devices set so that no conflicts exist for example, two add-in boards sharing the same interrupt?

6.

Is the power supply set to the proper input voltage (110V/120V or 220V/240V)?

7.

Are adapter boards and disk drives installed correctly?

8.

Is a keyboard attached?

9.

Is a bootable hard disk (properly partitioned and formatted) installed?

10.

Does the BIOS support the drive you have installed, and if so, are the parameters entered correctly?

11.

Is a bootable floppy disk installed in drive A:?

12.

Are all memory SIMMs or DIMMs installed correctly? Try reseating them.

13.

Is the operating system properly installed?

Hardware Problems After Booting

If problems occur after the system has been running, and without having made any hardware or software changes, a hardware fault possibly has occurred. Here is a list of items to check in that case:

1.

Try reinstalling the software that has crashed or refuses to run.

2.

Try clearing CMOS RAM and running Setup.

3.

Check for loose cables, a marginal power supply, or other random component failures.

4.

A transient voltage spike, power outage, or brownout might have occurred. Symptoms of voltage spikes include a flickering video display, unexpected system reboots, and the system not responding to user commands. Reload the software and try again.

5.

Try reseating the memory modules (SIMMs, DIMMs, or RIMMs).

Problems Running Software

Problems running application software (especially new software) are usually caused by or related to the software itself, or are due to the fact that the software is incompatible with the system. Here is a list of items to check in that case:

1.

Does the system meet the minimum hardware requirements for the software? Check the software documentation to be sure.

2.

Check to see that the software is correctly installed. Reinstall if necessary.

3.

Check to see that the latest drivers are installed.

4.

Scan the system for viruses using the latest antivirus software.

Problems with Adapter Cards

Problems related to add-in boards are usually related to improper board installation or resource (interrupt, DMA, or I/O address) conflicts. [Chapter 4](#), "Motherboards and Buses," has a detailed discussion of these system resources, what they are, how to configure them, and how to troubleshoot them. Also be sure to check drivers for the latest versions and ensure that the card is compatible with your system and the operating system version you are using.

Sometimes adapter cards can be picky about which slot they are running in. Despite the fact that, technically, a PCI or ISA adapter should be able to run in any of the slots, minor timing or signal variations sometimes occur from slot to slot. I have found on numerous occasions that simply moving a card from one slot to another can make a failing card begin to work properly. Sometimes moving a card works just by the inadvertent cleaning (wiping) of the contacts that takes place when removing and reinstalling the card, but in other cases I can duplicate the problem by inserting the card back into its original slot. When all else fails, try moving the cards around! Because some motherboards share a single IRQ between two PCI slots or between a PCI and an AGP slot, changing one of the PCI cards to another slot can resolve conflicts.

Caution

Note that PCI cards become slot specific after their drivers are installed. By this I mean that if you move the card to another slot, the plug-and-play resource manager sees it as if you have removed one card and installed a new one. You therefore must install the drivers all over again for that card. Don't move a PCI card to a different slot unless you are prepared with all the drivers at hand to perform the driver installation. ISA cards don't share this quirk because the system is not aware of which slot an ISA card is in.

Top Troubleshooting Problems

These are some of the most frequently asked troubleshooting questions I receive.

When I power the system on, I see the power LED light and hear the fans spin, but nothing else ever happens.

The fact that the LEDs illuminate and fans spin indicates that the power supply is partially working, but that does not exclude it from being defective. This is a classic "dead" system, which can be caused by almost any defective hardware component. In my experiences I've had more problems with power supplies than most other components, so I recommend immediately using a multimeter to measure the outputs at the power supply connectors and ensure they are within the proper 5% tolerances of their rated voltages. Even if the voltage measurements checked out, you should swap in a high-quality, high-power, known-good spare supply and retest. If that doesn't solve the problem, you should revert to the bootstrap approach I mentioned earlier, which is to strip the system down to just the chassis/power supply, motherboard, CPU (with heatsink), one bank of RAM (one DIMM), and a video card and display. If the motherboard now starts, begin adding the components you removed one at a time, retesting after each change. If the symptoms remain, use a POST card (if you have one) to see whether the board is partially functional and where it stops. Also, try replacing the video card, RAM, CPU, and then finally the motherboard, and verify the CPU and (especially) the heatsink installation.

The system beeps when I turn it on, but there is nothing on the screen.

The beep indicates a failure detected by the ROM POST routines. Look up the beep code in the table corresponding to the ROM version in your motherboard. This can typically be found in the motherboard manual; however, you can also find the beep codes for the most popular AMI, Award, and PhoenixBIOS earlier in this chapter.

I see a **STOP** or **STOP ERROR** in Windows NT/2000/XP.

Many things, including corrupted files, viruses, incorrectly configured hardware, and failing hardware, can cause Windows **STOP** errors. The most valuable resource for handling any error message displayed by Windows is the Microsoft Knowledgebase (MSKB), an online compendium of more than 250,000 articles covering all Microsoft products. You can visit the MSKB at support.microsoft.com, and from there you can use the search tool to retrieve information specific to your problem. For example, say you are receiving **Stop 0x0000007B** errors in Windows XP. In this case, you should visit the MSKB and enter the error message in the search box. In this case, I typed **stop 7B error Windows XP** in the box, and it returned two articles, one of which was Microsoft Knowledgebase Article number 324103, titled, "HOW TO: Troubleshoot "Stop 0x0000007B" Errors in Windows XP." Upon this link, I was taken to the article at support.microsoft.com/default.aspx?scid=kb;en-us;324103, which has a complete description of the problem and solutions. The article states that this error could be caused by the following:

- Boot-sector viruses
- Device driver issues
- Hardware issues
- Other issues

The article explains each issue and solution in detail. All things considered, the MSKB is a valuable resource when dealing with any problems related to or reported by any version of Windows or any other Microsoft software.

I see **Fatal Exception** errors in Windows 95/98/Me.

This is the equivalent of the **STOP** error in Windows NT/2000/XP. As indicated in the previous answer, this can be caused by both hardware and software problems, and the best place to check for specific solutions is in the Microsoft Knowledgebase (MSKB) at support.microsoft.com.

The system won't shut down in Windows.

This is another example where the MSKB comes to the rescue. For example, by searching for **shut down problems Windows XP**, (substitute the version of Windows you are using), you will quickly find several articles that can help you troubleshoot this type of problem. This problem has been caused by bugs in motherboard ROM (try upgrading your motherboard ROM to the latest version), bugs in the various Windows versions (visit www.windowsupdate.com and install the latest fixes, patches, and service packs), or in some cases configuration or hardware problems. I'll defer to the MSKB articles for more complete explanations of the Windows issues.

The power button won't turn off the system.

Desktop PCs built since 1996 mostly use the ATX form factor, which incorporates a special power supply design such that the power switch is connected to the motherboard and not the power supply directly. This enables the motherboard and operating system to control system shutdown, preventing an unexpected loss of power that can cause data loss or file system corruption. However, if the system experiences a problem

and becomes frozen or locked up in some way, the motherboard might not respond to the power button, meaning it will not send a shutdown signal to the power supply. It might seem that you will have to pull the plug to power off the system, but fortunately a forced shutdown override is provided. Merely press and hold down the system power button (usually on the front of the chassis) for a minimum of 4 seconds, and the system should power off. The only drawback is that, because this type of shutdown is forced and under the control of the motherboard or operating system, unsaved data can be lost and some file system corruption can result. You should therefore run ScanDisk (found in the Windows Accessories, System Tools folder) in Windows 95/98/Me/NT/2000 or Chkdsk in Windows XP to check and correct any file-system issues after a forced shutdown.

The modem doesn't work.

First verify that the phone line is good and that you have a dial tone. Then check and, if necessary, replace the phone cable from the modem to the wall outlet. If the modem is integrated into the motherboard, check the BIOS Setup to ensure that the modem is enabled. Try clearing the Enhanced System Configuration Data (ESCD) in the BIOS Setup. This forces the plug-and-play routines to reconfigure the system, which can resolve any conflicts. If the modem is internal and you aren't using the COM1/COM2 serial ports integrated into the motherboard (as for an external modem), try disabling the serial ports to free up additional system resources. Also, try removing and reinstalling the modem drivers, ensuring that you are using the most recent drivers from the modem manufacturer. If that doesn't help, try physically removing and reinstalling the modem. If the modem is internal, install it in a different slot. Or, if the modem is external, make sure it has power and is properly connected to the serial or USB port on the PC. Try replacing the external modem power brick and the serial/USB cable. Finally, if you get this far and it still doesn't work, try replacing the modem and finally the motherboard.

Note that modems are very susceptible to damage from nearby lightning strikes. Consider adding lightning arrestors or surge suppressors on the phone line running to the modem, and unplug the modem during storms. If the modem has failed after a storm, you can be almost certain that it has been damaged by lightning. The strike might have damaged the serial port or motherboard, in addition to the modem. Any items damaged by lightning will most likely need to be replaced.

The keyboard doesn't work.

The two primary ways to connect a keyboard to a PC are either via the standard keyboard port (usually called a PS/2 port) or via USB. One problem is that many older systems that have USB ports cannot use a USB keyboard because USB support is provided by the operating system for instance, if the motherboard has a USB port but does not include what is called USB Legacy Support in the BIOS. This support is specifically for USB keyboards (and mice) and was not common in systems until 1998 or later. Many systems that had such support in the BIOS still had problems with the implementation; in other words, they had bugs in the code that prevented the USB keyboard from working properly. If you are having problems with a USB keyboard, check to ensure that USB Legacy Support is enabled in the BIOS. If you are still having problems, make sure you have installed the latest BIOS for your motherboard and any Windows updates from Microsoft. Some older systems never could properly use a USB keyboard, in which case they should change to a PS/2 keyboard instead. Some keyboards feature both USB and PS/2 interfaces, which offer the flexibility to connect to almost any system.

If the keyboard is a PS/2 type and is having problems, the quickest way to verify whether it is the keyboard or the motherboard is to replace the keyboard with a known-good spare. In other words, borrow a working keyboard from another system and try it. If it still doesn't work, the keyboard controller on the motherboard is most likely defective, meaning the entire board must be replaced. My favorite replacement keyboards come from the PC Keyboard Co. (www.pckeyboard.com), which makes the legendary buckling spring design used by IBM. The company even offers versions with the Trackpoint pointing device built in.

I can't hear any sound from the speakers.

This can often be as simple as the speakers being unplugged or powered off, so don't overlook the obvious and check to be sure! Also check the volume controls in Windows or your application to see that they are turned up and not muted. When you are sure the volume is turned up and the speakers have power and are plugged in, you need to verify whether the problem is with the speakers or the sound card. To do this most efficiently, you merely connect different known-good speakers and see whether they work. If they don't, clearly the issue is in the sound card possibly the configuration of the card is incorrect or the card itself is defective. The first thing to try is clearing the ESCD in the BIOS Setup. This essentially forces the plug-and-play routines to reconfigure the system, which can resolve any conflicts. If this doesn't help, try removing and reinstalling the sound card drivers. Finally, if that doesn't help, physically remove and replace the card from the system. You might try replacing it first in the same slot and then in a different slot because timing issues can sometimes exist from one slot to the next. If that doesn't work, you must try replacing the card. If the sound "card" really isn't a card but is integrated into the motherboard, first try the ESCD reset and driver reinstallation. Then, if that doesn't work, you have to try disabling the integrated sound and perhaps installing a replacement card or replacement motherboard.

If your problem is only with playing audio CDs, check for a cable between the sound card and the drive. If there is no cable, check the properties for the drive in the Device Manager in Windows to see whether the Digital CD Audio option is checked (enabled). If it's not, enable it. If your system will not allow digital CD audio to be enabled, it is not supported and you must install an analog cable connected between the sound card and the drive.

The monitor appears completely garbled or unreadable.

A completely garbled screen is most often due to improper, incorrect, or unsupported settings for the refresh rate, resolution, or color depth. Using incorrect drivers can also cause this. To check the configuration of the card, the first step is to power on the system and verify whether you can see the POST or the system splash screen and enter the BIOS Setup. If the screen looks fine during the POST but goes crazy after Windows starts to load, the problem is almost certainly due to an incorrect setting or configuration of the card. To resolve this, boot the system in Windows Safe mode (hold down the F8 function key as Windows starts to load). This bypasses the current video driver and settings and places the system in the default VGA mode supported by the BIOS on the video card. When the Windows desktop appears, you can right-click the desktop, select Properties, and then either reconfigure the video settings or change drivers as necessary.

If the problem occurs from the moment you turn on the system and even if you boot to a DOS floppy (such as a Windows 98 startup floppy) a hardware problem definitely exists with the video card, cable, or monitor. First, replace the monitor with another one; if the cable is detachable, replace that, too. If replacing the monitor and cable does not solve the problem, the video card is probably defective. Either replace the card or, if it is a PCI-based card, move it to a different slot. If the video is integrated into the motherboard, you must add a separate card instead or replace the motherboard.

The image on the display is distorted (bent), shaking, or wavering.

This can often be caused by problems with the power line, such as an electric motor, an air conditioner, a refrigerator, and so on causing interference. Try replacing the power cord, plugging the monitor and/or the system into a different outlet, or moving it to a different location entirely. I've also seen this problem caused by local radio transmitters such as a nearby radio or television station or two-way radios being operated in the vicinity of the system. If the monitor image is bent and discolored, it could be due to the shadow mask being magnetized. Turn the monitor on and off repeatedly; this causes the built-in degaussing coil around the perimeter of the tube to activate in an attempt to demagnetize the shadow

mask. If this seems to work partially but not completely, you might need to obtain a professional degaussing coil from an electronics or TV service shop to demagnetize the mask. Next, replace the monitor cable, try a different (known-good) monitor, and finally replace the video card.

I purchased a video card, and it won't fit in the slot.

Most video cards are designed to conform to the AGP 4X, AGP 8X, or PCI Express x16 specification. It is all but impossible to install a PCI Express x16 card into a nonPCI Express x16 slot, but problems can arise with AGP cards when they're used with older AGP systems.

Both AGP 4X and AGP8X are designed to run on only 1.5V.

Most older motherboards with AGP 2X slots are designed to accept only 3.3V cards. If you were to plug a 1.5V card into a 3.3V slot, both the card and motherboard could be damaged. Special keys have therefore been incorporated into the AGP specification to prevent such disasters. Typically, the slots and cards are keyed such that 1.5V cards fit only in 1.5V sockets and 3.3V cards fit only in 3.3V sockets. Additionally, universal sockets are available that accept either 1.5V or 3.3V cards. The keying for the AGP cards and connectors is dictated by the AGP standard as shown in [Figure 22.12](#).

Figure 22.12. AGP 4X/8X (1.5V) card and how it relates to 3.3V, universal, and 1.5V AGP slots.

As you can see from [Figure 22.12](#), AGP 4X or 8X (1.5V) cards fit only in 1.5V or universal (3.3V or 1.5V)

slots. Due to the design of the connector and card keys, a 1.5V card cannot be inserted into a 3.3V slot. So, if your new AGP card won't fit in the AGP slot in your existing motherboard, consider that a good thing because, if you were able to plug it in, you would have fried both the card and the board! In a case such as this, you have to either return the 4X/8X card or get a new motherboard that supports 4X/8X (1.5V) cards.

I installed an upgraded processor, but it won't work.

First, make sure the motherboard supports the processor that is installed. Also make sure you are using the latest BIOS for your motherboard; check with the motherboard manufacturer to see whether any updates are available for download, and install them if any are available. Check the jumper settings (older boards) or BIOS Setup screens to verify that the processor is properly identified and set properly with respect to the FSB (or CPU bus) speed, clock multiplier, and voltage settings. Make sure the processor is set to run at its rated speed and is not overclocked. If any of the CPU settings in the BIOS Setup are on manual override, set them to automatic instead. Then reseal the processor in the socket. Next, make sure the heatsink is properly installed and you are using thermal interface material (that is, thermal grease) at the mating junction between the CPU and heatsink.

Just because a processor fits in the socket (or slot) on your motherboard does not mean it will work. For a processor to work in a system, the following things are required:

- *The CPU must fit in the socket.* Refer to [Chapter 3](#), "Microprocessor Types and Specifications," for a complete guide to the various CPU socket types and which processors are compatible with them.
- *The motherboard must support the voltage required by the CPU.* Modern motherboards set voltages by reading voltage ID (VID) pins on the processor and then setting the onboard voltage regulator module (VRM) to the appropriate settings. Older boards might not support the generally lower voltage requirements of newer processors.
- *The motherboard ROM BIOS must support the CPU.* Modern boards also read the CPU to determine the proper FSB (or CPU bus) speed settings as well as the clock multiplier settings for the CPU. Many CPUs have different requirements for cache settings and initialization, as well as for bug fixes and workarounds.
- *The motherboard chipset must support the CPU.* In some cases, specific chipset models or revisions might be required to support certain processors.

Before purchasing an upgraded processor for your system, you should first check with the motherboard manufacturer to see whether your board supports the processor. If so, it will meet all the requirements listed previously. Often, BIOS updates are available that enable newer processors to be supported in older boards, beyond what was originally listed in the manual when you purchased the board. The only way to know for sure is to check with the motherboard manufacturer for updated information regarding supported processors for a particular board.

As a specific example, some versions of the Pentium 4 that support hyper threading (HT) technology (one processor acts as if it were two processors, increasing performance) have dual-cores or neither of these features. If you have a system that uses the original non-HT, nondual-core Pentium 4 CPU, it would be great to be able to simply purchase one of these newer processors as an upgrade for an existing Pentium 4 system. Unfortunately, many existing boards do not accept these new processors. If you are considering replacing an existing Pentium 4 with a new HT technology or dual-core version, you need to verify that the motherboard supports this processor (in many cases it won't). Some older boards might be capable of supporting a newer CPU with only a BIOS upgrade, but many boards do not meet the chipset and front side bus speed requirements. In that case, you need a new processor, a new motherboard, and in all likelihood new memory to perform such an upgrade.

The system runs fine for a few minutes but then freezes or locks up.

This is the classic symptom of a system that is overheating. Most likely the CPU is overheating, but other components such as the video card or motherboard chipset can also be overheating. If the system is new or custom built, the design might be insufficient for proper cooling, and bigger heatsinks, more fans, or other solutions might be required. If the system was working fine but now is exhibiting this problem, check to see whether the problem started after any recent changes were made. If so, then whatever change was made could be the cause of the problem. If no changes were made, most likely something such as a cooling fan is either failed or starting to fail.

Modern systems should have several fans, one inside the power supply, one on the CPU (or positioned to blow on the CPU), and optionally others for the chassis. Verify that any and all fans are properly installed and spinning. They should not be making grinding or growling noises, which usually indicates bearing failure. Many newer systems have thermostatically controlled fans; in these systems it is normal for the fan speeds to change with the temperature. Make sure that the chassis is several inches from walls and that the fan ports are unobstructed. Try removing and reseating the processor; then reinstall the CPU heatsink with new thermal interface material. Check the power supply and verify that it is rated sufficiently to power the system (most should be 300 watts or more). Use a digital multimeter to verify the voltage outputs of the power supply, which should be within $\pm 5\%$ of the rated voltage at each pin. Try replacing the power supply with a high-quality replacement or known-good spare.

I am experiencing intermittent problems with the hard drive(s).

Most systems use ATA (AT-Attachment, commonly called IDE) interface drives, which consist of a drive and integrated controller, a ribbon cable, and a host adapter circuit in the motherboard. Typically, intermittent problems are found with the cable and the drive; it is far more rare that the host adapter fails or exhibits problems. Many problems occur with the cables. ATA drives use either 40-conductor or 80-conductor cables, with one 40-pin connector at either end and optionally one in the middle. Drives supporting transfer rates higher than ATA-33 (33MBps or Ultra DMA Mode 2) must use 80-conductor cables. Check the cable to ensure that it is not cut or damaged; then try unplugging and replugging it into the drive and motherboard. Check to see that the cable is not more than 18" (46cm) in length because that is the maximum allowed by the ATA specification. This is especially important when you are using the faster ATA-100 or ATA-133 transfer rates. Try replacing the cable with a new 80-conductor 18" version.

If replacing the cable does not help, replace the drive with a spare, install an OS, and test it to see whether the problem remains. If the problem does remain, the problem is with the motherboard, which will most likely need to be replaced. Alternatively, you could try adding a separate ATA 133 PCI card and attaching the drives to that, but in many cases a newer motherboard will give you more bang for your buck.

If the problem does not remain, the problem is most likely with your original drive. You can simply replace it or try testing, formatting, and reinstalling to see whether the drive can be repaired. To do this, you need the low-level format or test software provided by the drive manufacturer. You can find out more about where to get this for various makes of drives in [Chapter 12](#), "Physical Drive Installation and Configuration."

The system won't boot up; it says `Missing operating system` on the screen.

When your system boots, it reads the first sector from the hard disk called the master boot record (MBR) and runs the code contained in that sector. The MBR code then reads the partition table (also contained in the MBR) to determine which partition is bootable and where it starts. Then it loads the first sector of the bootable partition called the volume boot record (VBR) which contains the operating-system-specific boot code. However, before executing the VBR, the MBR checks to ensure that the VBR ends with the signature bytes `55AAh`. The `Missing operating system` message is displayed by the MBR if it finds that the first sector of the bootable partition (the VBR) does not end in `55AAh`.

Several things can cause this to occur, including these:

- *The drive parameters entered in the BIOS Setup are incorrect or corrupted.* These are the parameters defining your drive that you entered in the BIOS Setup, and they're stored in a CMOS RAM chip powered by a battery on your motherboard. Incorrect parameters cause the MBR program to translate differently and read the wrong VBR sector, thus displaying the **Missing operating system** message. A dead CMOS battery can also cause this because it loses or corrupts the stored drive translation and transfer mode parameters. In fact, in my experience, a dead battery is one of the more likely causes. To repair, check, and replace the CMOS battery, run the BIOS Setup, go to the hard drive parameter screen, and enter the correct drive parameters. Note that most drive parameters should be set to auto or autodetect.
- *The drive is not yet partitioned and formatted on this system.* This is a normal error if you try to boot the system from the hard disk before the OS installation is complete. Boot to an OS startup disk (floppy or CD), and run the SETUP program, which will prompt you through the partitioning and formatting process during the OS installation.
- *The MBR and/or partition tables are corrupt.* This can be caused by boot sector viruses, among other things. To repair this, *cold* boot (power off, then on) from a known, noninfected, write-protected floppy or bootable CD containing the FDISK program (preferably Win98 or later). Enter **FDISK/MBR** at the command prompt, which recopies the MBR code but doesn't alter the partition table. Then reboot. If the message persists, and you need to recover the data on the drive, you then must either rebuild the partition tables from scratch using a third-party utility such as the DISKEDIT program included with the Symantec Norton Utilities or hire a data recovery specialist who can do this for you. If you don't need to recover the data on the drive, simply reinstall the OS from scratch, which will prompt you through partitioning and formatting the drive.
- *The VBR is corrupt.* To repair with Windows 95/98/Me, secure a bootable floppy that was created by the same OS version as is on the hard disk and that contains the **SYS** command from that OS. Run **SYS C:**, which recopies a good VBR and system files to the volume. For Windows NT/2000/XP, you can use the Recovery Console or DiskProbe utilities (found on the bootable operating system CD).

The system is experiencing intermittent memory errors.

If the memory was recently added or some other change was made to the system, you should undo that addition/change to see whether it is the cause. If it's not, remove and reseat all memory modules. If the contacts look corroded, clean them with contact cleaner and then apply contact enhancer for protection. Check the memory settings in the BIOS Setup; generally, all settings should be on automatic. Next, upgrade to the latest BIOS for your motherboard, and remove all memory except one bank. Then run only one bank of memory, but in the second or third bank position. A socket can develop a problem, and most motherboards do not require that the sockets be filled in numerical order. Also, replace the remaining module with one of the others that was removed, a new module, or a known-good spare.

If you get this far, the problem is most likely either the motherboard or the power supply or possibly some other component in the system. Remove other components from the system to see whether they are causing problems. Reseat the CPU, and replace the power supply with a high-quality new unit or a known-good spare. Finally, try replacing the motherboard.

The system locks up frequently and sometimes reboots on its own.

This is one of the classic symptoms of a power supply problem. The power supply is designed to send a special Power_Good signal to the motherboard when it has passed its own internal tests and outputs are stable. If this signal is dropped, even for an instant, the system resets. Problems with the power good circuit cause lockups and spontaneous rebooting. This can also be caused if the power at the wall outlet is not correct. Verify the power supply output with a digital multimeter all outputs should be within +/-5% of

the rated voltages. Use a tester for the wall outlet to ensure that it is properly wired, and verify that the voltage is near 120V. Replace the power cord or power strip between the power supply and wall outlet.

Unfortunately, the intermittent nature makes this problem hard to solve. If the problem is not with the wall outlet power, the best recourse is to replace the power supply with a high-quality new unit or a known-good spare of sufficient rating to handle the system (300 watts or higher recommended). If this doesn't help, reseal the CPU and reinstall the heatsink with new thermal interface material. Then reseal the memory modules, run only one bank of memory, and finally replace the motherboard.

I installed a 60GB drive in my system, but it is recognizing only 8.4GB.

Motherboard ROM BIOSs have been updated throughout the years to support larger and larger drives. BIOSs older than August 1994 are typically limited to drives of up to 528MB, whereas BIOSs older than January 1998 are limited to 8.4GB. Most BIOSs dated 1998 or newer support drives up to 137GB, and those dated September 2002 or newer should support drives larger than 137GB. These are only general guidelines; to accurately determine this for a specific system, you should check with your motherboard manufacturer. You can also use the BIOS Wizard utility from www.unicore.com/bioswiz/index2.html. It tells you the BIOS date from your system and specifically whether your system supports the Enhanced Hard Disk Drive specification, which means drives larger than 8.4GB.

If your BIOS does not support EDD (drives larger than 8.4GB), the three possible solutions are as follows:

- Upgrade your motherboard BIOS upgrade to a 1998 or newer version that supports >8.4GB.
- Install a BIOS upgrade card, such as the ATA Pro Flash from www.firmware.com or the Ultra ATA 133 PCI card from www.maxstore.com.
- Install a software patch to add >8.4GB support.

Of these, the first one is the most desirable because it is usually free. Visit your motherboard manufacturer's website to see whether it has any newer BIOSs available for your motherboard that will support large drives. If it doesn't, the next best thing is to use a card such as the Ultra ATA 133 PCI card from Maxtor. I almost never recommend the software patch solution because it merely installs a special driver in the boot sector area of the hard drive, which can result in numerous problems when booting from different drives, installing new drives, or recovering data.

The 137GB barrier is a bit more complicated because, in addition to BIOS issues, operating system and chipset-based ATA host adapter driver issues are involved. Drives larger than 137GB are accessed using 48-bit logical block address (LBA) numbers, which require BIOS support, chipset driver support, and operating system support. Generally, you need a BIOS with 48-bit LBA support (normally dated September 2002 or newer), the latest chipset driver such as the Intel Application Accelerator (for motherboards using Intel chipsets, at www.intel.com/support/chipsets/iaa), and Windows XP with Service Pack 1 (or later) installed. If your motherboard BIOS does not provide the necessary support, the Maxtor Ultra ATA 133 PCI card listed earlier adds this support to your system. The original version of XP, as well as Windows 2000/NT or Windows 95/98/Me, does not currently provide native support for hard drives larger than 137GB.

If you have a system without BIOS support, check with your motherboard manufacturer for an update (or you can use a card with onboard BIOS, such as the Ultra ATA 133 PCI card from Maxtor). If your motherboard uses a non-Intel chipset, check with the motherboard or chipset manufacturer for driver updates to enable 48-bit LBA support.

My CD-ROM/DVD drive doesn't work.

CD and DVD drives are some of the more failure-prone components in a PC. It is not uncommon for one to suddenly fail after a year or so of use.

If you are having problems with a drive that was newly installed, check the installation and configuration of the drive. Check the jumper settings on the drive. If you're using an 80-conductor cable, the drive should be jumpered to Cable Select; if you're using a 40-conductor cable, the drive should be set to either master or slave (depending on whether it is the only drive on the cable). Check the cable to ensure that it is not nicked or cut and is a maximum of 18" long (the maximum allowed by the ATA specification). Replace the cable with a new one or a known-good spare, preferably using an 80-conductor cable. Make sure the drive power is connected, and verify that power is available at the connector using a digital multimeter. Also make sure the BIOS Setup is set properly for the drive, and verify that the drive is detected during the boot process. Finally, try replacing the drive and, if necessary, the motherboard.

If the drive had already been installed and was working before, first read different discs, preferably commercial-stamped discs rather than writeable or rewriteable ones. Then try the steps listed previously.

My USB port or device doesn't work.

Make sure you have enabled the USB ports in the BIOS Setup. Make sure your operating system supports USB. Windows 95 and NT do not, whereas Windows 98 and later do have USB support. Then remove any hubs and plug the device directly into the root hub connections on your system. Replace the cable. Many USB devices require additional power, so ensure that your device has an external power supply connected if one is required. Replace the power supply.

I installed an additional memory module, but the system doesn't recognize it.

Verify that the memory is compatible with your motherboard. Many subtle variations exist on memory types that can appear to be identical on the surface. Just because it fits in the slot does not mean the memory will work properly with your system. Check your motherboard manual for the specific type of memory your system requires, and possibly for a list of supported modules. You can visit www.crucial.com and use its Memory Advisor Tool to determine the exact type of memory for a specific system or motherboard. Also note that all motherboards have limits to the amount of memory they support, and many boards today support only up to 512MB or 1GB. Again, consult the motherboard manual or manufacturer for information on the limits for your board.

If you are sure you have the correct type of memory, follow the memory troubleshooting steps listed previously for intermittent memory problems.

I installed a new drive, but it doesn't work and the drive LED remains lit.

This is the classic symptom for a cable plugged in backward. Both ATA and floppy drives are designed to use cables with keyed connectors; however, some cables are available that lack this keying, which means they can easily be installed backward. When the cable is installed backward into either the motherboard or the drive, the LED on the drive remains lit and the drive does not function. In some cases, this can also cause the entire system to freeze. Check the cables to ensure that they are plugged in properly at both ends; the stripe on the cable indicates pin-1 orientation. On the drive, pin-1 typically is oriented toward the power connector. On the motherboard, look for orientation marks silk-screened on the board or observe the orientation of the other cables plugged in (all cables follow the same orientation).

While I was updating my BIOS, the system froze and now the system is dead!

This can occur when a flash ROM upgrade goes awry. Fortunately, most motherboards have a recovery routine that can be enabled via a jumper on the board. When enabled, the recovery routine causes the system to look for a floppy with the BIOS update program on it. If you haven't done so already, you need to download an updated BIOS from the motherboard manufacturer and follow its directions for placing the BIOS update program on a bootable floppy. Then set BIOS recovery mode via the jumper on the motherboard, power on the system, and wait until the procedure completes. It usually take up to 5 minutes, and you might hear beeping to indicate the start and end of the procedure. When the recovery is complete, turn off the system and restore the recovery jumper to the original (normal) settings.

If your motherboard does not feature BIOS recovery capability, you might have to send the board to the manufacturer for repair.

I installed a new motherboard in an older Dell system, and nothing works.

Many older Dell Dimension systems (Dimension 4100, 8100, or older systems) do not fully conform to the ATX specification with respect to their power supplies and the power connectors on their motherboards. If you replace one of these nonstandard Dell power supplies with a standard ATX type, or replace the nonstandard Dell motherboard with a standard ATX type, you risk frying both the power supply and the motherboard. The older Dell systems can be upgraded only by replacing both the motherboard and the power supply at the same time.

Starting in 2001, Dell converted to using industry-standard ATX power supplies and motherboard power connectors for its systems, so this should not be a problem for the Dimension 4200, 8200, and later machines.

I installed a PCI video card in an older system with PCI slots, and it doesn't work.

The PCI bus has gone through several revisions; most older slots are "2.0" type, and most newer cards need "2.1" or later PCI slots. The version of PCI your system has is dictated by the motherboard chipset. If you install a newer video or other PCI card that requires 2.1 slots in a system with 2.0 slots, often the system won't boot up or operate at all.

If you check the chipset reference information in [Chapter 4](#), you might be able to determine which revision of PCI slots your motherboard has by knowing which chipset it has. If this is your problem, the only solution is to change either the card or motherboard so that they are both compatible.

A. Glossary

This glossary contains computer and electronics terms that are applicable to the subject matter in this book. The glossary is meant to be as comprehensive as possible on the subject of upgrading and repairing PCs. Many terms correspond to the latest technology in disk interfaces, modems, video and display equipment, and standards that govern the PC industry. Although a glossary is a resource not designed to be read from beginning to end, you should find that scanning through this one is interesting, if not enlightening, with respect to some of the newer PC technology.

The computer industry is filled with abbreviations used as shorthand for a number of terms. This glossary defines many abbreviations, as well as the terms on which the abbreviations are based. The definition of an abbreviation usually is included under the acronym. For example, *video graphics array* is defined under the abbreviation *VGA* rather than under *video graphics array*. This organization makes looking up a term easier *IDE*, for example even if you do not know in advance what it stands for (*integrated drive electronics*).

These websites can also help you with terms not included in this glossary:

webservices.cnet.com/cgi/Glossary.asp

www.webopedia.com

whatis.techtarget.com

150X

CD-ROM maximum speeds in relation to the speed of a music CD (1X = 150KBps). At speeds of 16X or above, most drives are CAV and reach their rated speeds only on the outer edges of the disc. See also [CLV](#) and [CAV](#).

3GIO

The original name for PCI Express, a forthcoming replacement for existing PCI connections. See also [PCI Express](#).

10BASE-2

IEEE standard for baseband Ethernet at 10Mbps over RG-58 coaxial cable to a maximum distance of 185 meters. Also known as Thin Ethernet (Thinnet) or IEEE 802.3.

10BASE-5

IEEE standard for baseband Ethernet at 10Mbps over thick coaxial cable to a maximum distance of 500 meters. Also known as Thick Ethernet or Thicknet.

10BASE-T

A 10Mbps CSMA/CD Ethernet LAN that works on Category 3 or better twisted-pair wiring, which is very similar to standard telephone cabling. 10BASE-T Ethernet LANs work on a "star" configuration, in which the wire from each workstation routes directly to a 10BASE-T hub. Hubs can be joined together. 10BASE-T has a maximum distance of 100 meters between each workstation and the hub.

24x7

Refers to continuous 24 hours a day, 7 days a week computer or services operation.

56K

The generic term for modems that can receive data at a maximum rate of 56Kbps. See also [V.90](#), [V.92](#), [X2](#), [K56flex](#).

64-bit processor

A processor that has 64-bit registers. The Intel Itanium and Itanium 2 processors for workstations and servers, which can also emulate 32-bit Intel processors; the AMD Athlon 64 desktop processor, which also emulates 32-bit x86 Intel and AMD processors; and the AMD Opteron, designed for use in server and workstation tasks, are some of the 64-bit processors now available.

100BASE-T

A 100Mbps CSMA/CD Ethernet local area network (LAN) that works on Category 5 twisted-pair wiring. 100BASE-T Ethernet LANs work on a "star" configuration in which the wire from each workstation routes directly to a central 100BASE-T hub. This is the current standard for 100Mbps Ethernet, replacing 100BASE-VG.

100BASE-VG

The joint Hewlett-Packard/AT&T proposal for Fast Ethernet running at 100Mbps. It uses four pairs of Category 5 cable using the 10BASE-T twisted-pair wiring scheme to transmit or receive. 100BASE-VG splits the signal across the four wire pairs at 25MHz each. This standard has not found favor with corporations and has been almost totally replaced by 100BASE-T.

286

See [80286](#).

386

See [80386DX](#).

404

website error code indicating the specified page is not found. Some websites display a customized error message instead of the standard 404 code.

486

See [80486DX](#).

586

A generic term used to refer to fifth-generation processors similar to the Intel Pentium, such as the AMD K6 series and the VIA Cyrix MII.

640KB barrier

The limit imposed by the PC-compatible memory model using DOS mode. DOS programs can address only 1MB total memory, and PC compatibility generally requires the top 384KB to be reserved for the system, leaving only the lower 640KB for DOS or other real-mode applications.

802.11

The family name for various wireless Ethernet standards. See also [IEEE 802.11 family](#).

1000BASE-T

A 1,000Mbps Ethernet local area network (LAN) that runs over four pairs of Category 5 cable. Popularly known as Gigabit Ethernet, 1000BASE-T can be used as an upgrade to a properly wired 100BASE-T network because the same cable and distance limitations (100 meters) apply.

1394

See [FireWire](#).

8086

An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 20-bit address bus. This processor can operate only in real mode.

8087

An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 8087 can be installed in most 8086- and 8088-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

8088

An Intel microprocessor with 16-bit registers, an 8-bit data bus, and a 20-bit address bus. This processor can operate only in real mode and was designed as a low-cost version of the 8086.

8514/A

An analog video display adapter from IBM for the PS/2 line of personal computers. Compared to previous display adapters, such as EGA and VGA, it provides a high resolution of 1,024x768 pixels with as many as 256 colors or 64 shades of gray. It provides a video coprocessor that performs two-dimensional graphics functions internally, thus relieving the CPU of graphics tasks. It uses an interlaced monitor and scans every other line every time the screen is refreshed.

80286

An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 24-bit address bus. It can operate in both real and protected virtual modes.

80287

An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80287 can be installed in most 286- and some 386DX-based systems, and it adds more than 50 new instructions to what is available in the primary CPU alone.

80386

See [80386DX](#).

80386DX

An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. This processor can operate in real, protected virtual, and virtual real modes.

80386SX

An Intel microprocessor with 32-bit registers, a 16-bit data bus, and a 24-bit address bus. This processor, designed as a low-cost version of the 386DX, can operate in real, protected virtual, and virtual real modes.

80387DX

An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387DX can be installed in most 386DX-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

80387SX

An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387SX can be installed in most 386SX-based systems and adds

more than 50 new instructions to those available in the primary CPU alone.

80486

See [80486DX](#).

80486DX

An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486DX has a built-in cache controller with 8KB of cache memory as well as a built-in math coprocessor equivalent to a 387DX. The 486DX can operate in real, protected virtual, and virtual real modes.

80486DX2

A version of the 486DX with an internal clock-doubling circuit that causes the chip to run at twice the motherboard clock speed. If the motherboard clock is 33MHz, the DX2 chip will run at 66MHz. The DX2 designation applies to chips sold through the OEM market, whereas a retail version of the DX2 sold by Intel and designed for use as an upgrade was sold as an Overdrive processor.

80486DX4

A version of the 486DX with an internal clock-tripling circuit that causes the chip to run at three times the motherboard clock speed. If the motherboard clock is 33.33MHz, the DX4 chip will run at 100MHz.

80486SX

An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486SX is the same as the 486DX, except that it lacks the built-in math coprocessor function and was designed as a low-cost version of the 486DX. The 486SX can operate in real, protected virtual, and virtual real modes.

80487SX

An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. Although the name implies that the 80487SX adds floating-point math capabilities, in reality the 487SX is the same as the 486DX, except that it uses a modified pinout and must be installed in a special 80487SX socket. When installed, the 80487SX replaces the 80486SX for all processing tasks. The 487SX can operate in real, protected virtual, and virtual real modes.

A+

Refers to the CompTIA A+ Certification, a vendor-neutral certification for computer hardware technicians. A+ Certification exams test knowledge of basic hardware and software skills. The A+ Certification can be used as part of the exam requirements for the Microsoft Certified System Administrator (MCSA) credential.

abend

Short for *abnormal end*. A condition occurring when the execution of a program or task is terminated unexpectedly because of a bug or crash.

absolute address

An explicit identification of a memory location, device, or location within a device.

AC (alternating current)

The frequency is measured in cycles per seconds (cps) or hertz (Hz). The standard value running through the wall outlet is 120 volts at 60Hz through a fuse or circuit breaker that usually can handle about 15 or 20 amps.

accelerated graphics port

See [AGP](#).

Accelerated Hub Architecture (AHA)

An Intel technology used on its 800-series chipsets to transfer data between the memory controller hub (MCH), which is equivalent to the North Bridge, and the input/output controller hub (ICH), which is equivalent to the South Bridge. AHA transfers data at 266MBps, twice the speed of the PCI bus previously used.

accelerator board

An add-in board replacing the computer's CPU with circuitry that enables the system to run more quickly. See also [graphics accelerator](#).

access light

The LED on the front of a drive or other device (or on the front panel of the system) that indicates the computer is reading or writing data on the device.

access mechanism

See [actuator](#).

access time

The time that elapses from the instant information is requested to the point that delivery is completed. It's usually described in nanoseconds (ns) for memory chips and in milliseconds (ms) for disk drives. Most manufacturers rate average access time on a hard disk as the time required for a

seek across one third of the total number of cylinders plus one-half the time for a single revolution of the disk platters (latency).

accumulator

A register (temporary storage) in which the result of an operation is formed.

acoustic coupler

A device used to connect a computer modem to a phone line by connecting to the handset of a standard AT&T-style phone. The audible sounds to and from the modem are transmitted to the handset through the coupler while the handset is resting in the coupler. Although often thought of as obsolete, an acoustic coupler can be used to ensure the availability of a modem connection when traveling and access to an RJ-11 jack is unavailable.

ACPI (Advanced Configuration and Power Interface)

A standard developed by Intel, Microsoft, and Toshiba that is designed to implement power management functions in the operating system. ACPI is a replacement for APM. See also [APM](#).

ACR

Short for Advanced Communication Riser, an alternative to CNR advocated by the ACR Special Interest Group (www.acrsig.org). ACR, like CNR, is designed to allow motherboard designers to add low-cost network capabilities to motherboards but uses the same PCI connector used by PCI expansion cards.

Acrobat

Refers to the Adobe Acrobat program for creating and reading cross-platform documents created in Adobe's Portable Document Format (PDF) file format. Many computer and component manuals are available online in Acrobat format. The Acrobat Reader can be downloaded free from Adobe's website.

active heatsink

A heatsink that includes a fan. It's commonly used to cool processors and North Bridge/Memory Controller Hub chips.

active high

Designates a digital signal that must go to a high value to be true. Synonymous with positive.

active low

Designates a digital signal that must go to a low value to be true. Synonymous with negative.

active matrix

A type of LCD screen that contains at least one transistor for every pixel on the screen. Color active matrix screens use three transistors for each pixel one each for the red, green, and blue dots. The transistors are arranged on a grid of conductive material, with each connected to a horizontal and a vertical member. See also [TFT](#).

active partition

Any partition marked as bootable in the partition table. See also [boot manager](#).

actuator

The device that moves a disk drive's read/write heads across the platter surfaces. Also known as an access mechanism.

adapter

The device that serves as an interface between the system unit and the devices attached to it. It's often synonymous with circuit board, circuit card, or card, but it also can refer to a connector or cable adapter that changes one type of connector to another.

adapter description files (ADF)

Refers to the setup and configuration files and drivers necessary to install an adapter card, such as a network adapter card. Primarily used with Micro Channel Architecture (MCA) bus cards.

add-in board

See [expansion card](#).

address

Refers to where a particular piece of data or other information is found in the computer. Also can refer to the location of a set of instructions.

address bus

One or more electrical conductors used to carry the binary-coded address from the microprocessor throughout the rest of the system.

ADSL (asymmetric digital subscriber line)

A high-speed transmission technology originally developed by Bellcore and now standardized by ANSI as T1.413. ADSL uses existing UTP copper wires to communicate digitally at high speed

between the telephone company central office (CO) and the subscriber. ADSL sends information asymmetrically, meaning it is faster one way than the other. The original ADSL speed was T-1 (1.536Mbps) downstream from the carrier to the subscriber's premises and 16Kbps upstream. However, ADSL is available in a variety of configurations and speeds. See also [DSL](#).

AdvancedTCA

Advanced Telecom Computing Architecture is a new series of standards for telecom processor blades and chassis. It is also known as the PICMG 3.0 specification. See also [PICMG](#).

AGP (accelerated graphics port)

Developed by Intel, AGP is a fast, dedicated interface between the video adapter or chipset and the motherboard chipset North Bridge. AGP is 32 bits wide; runs at 66MHz base speed; and can transfer 1, 2, 4, or 8 bits per cycle (1x, 2x, 4x, or 8x modes) for a throughput of up to 2132MBps.

aliasing

Undesirable visual effects (sometimes called artifacts) in computer-generated images caused by inadequate sampling techniques. The most common effect is jagged edges along diagonal or curved object boundaries. See also [antialiasing](#).

allocation unit

See [cluster](#).

alphanumeric characters

A character set that contains only letters (AZ) and digits (09). Other characters, such as punctuation marks, also might be allowed.

AMD

Short for Advanced Micro Devices, the number-two PC processor maker. AMD makes the popular K6, Athlon, Opteron, and Duron series of processors, as well as chipsets and flash memory devices.

AMD64

AMD-developed 64-bit extensions to the standard IA-32 system architecture; originally known as x86-64. Supported by AMD Opteron, Athlon 64, and other AMD 64-bit processors.

ampere

The basic unit for measuring electrical current. Also called amp.

AMR

Short for Audio/Modem Riser, it's an Intel-developed specification for packaging modem I/O ports and a codec chip into a small card that can be installed into an AMR slot on a motherboard. Although many motherboards have AMR slots, AMR risers have not been popular, and the CNR specification has largely replaced AMR. See also [CNR](#).

analog

The representation of numerical values by physical variables such as voltage, current, and so on; continuously variable quantities whose values correspond to the quantitative magnitude of the variables.

analog loopback

A modem self-test in which data from the keyboard is sent to the modem's transmitter, modulated into analog form, looped back to the receiver, demodulated into digital form, and returned to the screen for verification.

analog signals

Continuously variable signals. Analog circuits are more subject to distortion and noise than are digital circuits but are capable of handling complex signals with relatively simple circuitry. See also [digital signals](#).

analog-to-digital converter

An electronic device that converts analog signals to digital form.

AND

A logic operator having the property that if P is a statement, Q is a statement, R is a statement..., then the AND of P, Q, R... is true if all statements are true and is false if any statement is false.

AND gate

A logic gate in which the output is 1 only if all inputs are 1.

animation

The process of displaying a sequential series of still images to achieve a motion effect.

ANSI (American National Standards Institute)

A nongovernmental organization founded in 1918 to propose, modify, approve, and publish data processing standards for voluntary use in the United States. It's also the U.S. representative to the International Standards Organization (ISO) in Paris and the International Electrotechnical

Commission (IEC). For more information, see the Vendor List on the disc packaged with this book. Contact ANSI, 1430 Broadway, New York, NY 10018.

answer mode

A state in which the modem transmits at the predefined high frequency of the communications channel and receives at the low frequency. The transmit/receive frequencies are the reverse of the calling modem, which is in originate mode. See also [originate mode](#).

antialiasing

Software adjustment to make diagonal or curved lines appear smooth and continuous in computer-generated images. See also [aliasing](#).

antistatic mat

A pad placed next to a computer upon which components are placed while servicing the system to prevent static damage. Also can refer to a larger-sized mat below an entire computer desk and chair to discharge static from a user before he touches the computer.

antivirus

Software that prevents files containing viruses from running on a computer or software that detects, repairs, cleans, or removes virus-infected files.

APA (all points addressable)

A mode in which all points of a displayable image can be controlled by the user or a program.

aperture grille

A type of shadow mask used in CRTs. The most common is used in Sony's Trinitron monitors, which use vertical phosphor stripes and vertical slots in the mask, compared to the traditional shadow mask that uses phosphor dots and round holes in the mask. See also [shadow mask](#).

API (application program interface)

A system call (routine) that gives programmers access to the services provided by the operating system. In IBM-compatible systems, the ROM BIOS and DOS together present an API that a programmer can use to control the system hardware.

APM (Advanced Power Management)

A specification sponsored by Intel and Microsoft originally proposed to extend the life of batteries in battery-powered computers. It is now used in desktop computers as well. APM enables application programs, the system BIOS, and the hardware to work together to reduce power consumption. An APM-compliant BIOS provides built-in power-management services to the operating system. The

application software communicates power-saving data via predefined APM interfaces. Replaced in newer systems by ACPI. See also [ACPI](#).

application

End-useroriented software, such as a word processor, spreadsheet, database, graphics editor, game, or web browser.

Application Layer

See [OSI](#).

arbitration

A method by which multiple devices attached to a single bus can bid or arbitrate to get control of that bus.

archive bit

The bit in a file's attribute byte that sets the archive attribute. Tells whether the file has been changed since it last was backed up.

archive file

A collection of files that has been stored (often in a compressed format) within a single file. Zip and CAB files are the most common types of archive file formats used with Windows-based PCs. See also [Zip file](#) and [CAB file](#).

archive medium

A storage medium (floppy disk, tape cartridge, or removable cartridge) to hold files that need not be accessible instantly.

ARCnet (Attached Resource Computer Network)

A baseband, token-passing LAN technology offering a flexible bus/star topology for connecting personal computers. Operating at 2.5Mbps, it is one of the oldest LAN systems and was popular in low-cost networks. It was originally developed by John Murphy of Datapoint Corporation. Although ARCnet (www.arcnet.com) is no longer used for office networking, it is still a popular choice for networking embedded systems, such as heating and air conditioning systems.

areal density

A calculation of the bit density (bits per inch, or BPI) multiplied by the track density (tracks per inch, or TPI), which results in a figure indicating how many bits per square inch are present on the disk surface.

ARQ (automatic repeat request)

A general term for error-control protocols that feature error detection and automatic retransmission of defective blocks of data.

ASCII (American Standard Code for Information Interchange)

A standard 7-bit code created in 1965 by Robert W. Bemer to achieve compatibility among various types of data processing equipment. The standard ASCII character set consists of 128 decimal numbers ranging from 0 to 127, which are assigned to letters, numbers, punctuation marks, and the most common special characters. In 1981, IBM introduced the extended ASCII character set with the IBM PC, extending the code to 8 bits and adding characters from 128 to 255 to represent additional special mathematical, graphics, and foreign characters.

ASCII character

A 1-byte character from the ASCII character set, including alphabetic and numeric characters, punctuation symbols, and various graphics characters.

ASME (American Society of Mechanical Engineers; www.asme.org)

ASME International has nearly 600 codes and standards in print, and its many committees involve more than 3,000 individuals, mostly engineers but not necessarily members of the society. The standards are used in more than 90 countries throughout the world.

aspect ratio

The measurement of a film or television viewing area in terms of relative height and width. The aspect ratio of most modern motion pictures varies from 5:3 to as large as 16:9, which creates a problem when a wide-format motion picture is transferred to the more square-shaped television screen or monitor, with its aspect ratio of 4:3. See also [letterbox](#).

assemble

The act of translating a program expressed in an assembler language into a computer machine language.

assembler language

A computer-oriented language whose instructions are usually in one-to-one correspondence with machine language instructions.

asymmetrical modulation

A duplex transmission technique that splits the communications channel into one high-speed channel and one slower channel. During a call under asymmetrical modulation, the modem with the

greater amount of data to transmit is allocated the high-speed channel. The modem with less data is allocated the slow, or back, channel. The modems dynamically reverse the channels during a call if the volume of data transfer changes.

asynchronous communication

Data transmission in which the length of time between transmitted characters can vary. Timing depends on the actual time for the transfer to take place, as opposed to synchronous communication, which is timed rigidly by an external clock signal. Because the receiving modem must be signaled about when the data bits of a character begin and end, start and stop bits are added to each character. See also [synchronous communication](#).

asynchronous memory

Memory that runs using a timing or clock rate different from (usually slower than) the motherboard speed.

AT clock

Refers to the Motorola 146818 real-time clock (RTC) and CMOS RAM chip, which first debuted in the IBM AT and whose function has been present in all PC-compatible systems since. Keeps track of the time of day and makes this data available to the operating system or other software.

ATA (AT Attachment Interface)

An IDE disk interface standard introduced in March 1989 that defines a compatible register set, a 40-pin connector, and its associated signals. See also [IDE](#) and [SATA](#).

ATA-2

The second-generation AT Attachment Interface specification, approved in 1996. This version defines faster transfer modes and logical block addressing schemes to allow high-performance, large-capacity drives. Also called Fast ATA, Fast ATA-2, and enhanced IDE (EIDE).

ATA-3

Published in 1997, ATA-3 defines 8-bit DMA transfers and SMART support for drive failure prediction.

ATA/ATAPI -4

The fourth-generation ATA specification was published in 1998. ATA/ATAPI-4 incorporates ATAPI and adds Ultra DMA/33 (33MBps) transfer mode; APM support; an optional 80-wire, 40-pin cable; support for Compact Flash memory devices; and enhanced BIOS support for larger drives.

ATA/ATAPI -5

Approved in 2000, ATA/ATAPI-5 includes UDMA/66 support, mandates the 80-wire cable for

UDMA/66, detects the cable type, and allows UDMA/66 or faster speeds only if the 80-wire cable is present.

ATA/ATAPI-6

The latest draft standard, ATA/ATAPI-6 includes UDMA/100 (100MBps) support and increases the ATA drive size limit to 144.12PB (petabytes). See also [petabyte](#).

ATAPI (AT Attachment Packet Interface)

A specification that defines device-side characteristics for an IDE-connected peripheral, such as a CD-ROM or tape drive. ATAPI is essentially an adaptation of the SCSI command set to the IDE interface. ATA-4 and newer ATA standards include ATAPI standards.

Athlon

An AMD sixth-generation processor family roughly comparable to the Intel Pentium III and Pentium 4. Later models (beginning with the Thunderbird core) include on-die L2 cache running at full core speed. It includes MMX and AMD 3DNow! instructions for multimedia performance. Originally available in a Slot-A cartridge package, all Athlons are now available only in the Socket-A (462-pin) package. The Mobile Athlon XP, which replaced the Athlon 4, is designed for mobile applications, the Athlon MP is designed for workstation/server multiprocessor configurations, and the Athlon XP is designed mainly for single processor applications. All three use the improved Thoroughbred core and 3DNow! Professional multimedia extensions. The Athlon XP processors include AMD's new QuantiSpeed design for faster internal operation and are rated by their performances relative to the Intel Pentium 4, rather than by their clock speeds. For example, the Athlon XP 2600+, which performs comparably to the Pentium 4 2.6GHz processor, runs at a clock speed of about 2.1GHz.

Athlon 64

An AMD processor (code-named Clawhammer) that uses a 64-bit internal design. The Athlon 64 also emulates 32-bit x86 processors from Intel and AMD. It uses a new ball grid array socket called Socket 754; an integrated DDR memory controller (instead of using the North Bridge for memory connections); an improved version of the AMD-developed HyperTransport connection to AGP, PCI, and other components; and an improved heatsink-mounting solution. It supports MMX and AMD 3dNow! Instructions for multimedia and uses a performance-rating system similar to that used by 32-bit Athlon processors. See also [Athlon](#). See also [Socket 754](#).

Athlon 64 FX

An AMD processor based on the Athlon 64, but offering an integrated dual-channel memory controller, faster clock speeds, and a 1MB memory cache in all models. Initial versions used Socket 940, but later models use Socket 939. See also [Socket 939](#) and [Socket 940](#).

Athlon 64 X2

A dual-core version of the AMD Athlon 64 processor that features separate L2 memory caches for each core and an integrated crossbar memory switch for fast transfer of information between each core. This processor uses Socket 939. See also [Socket 939](#).

ATM (asynchronous transfer mode)

A high-bandwidth, low-delay, packet-like switching and multiplexing technique. Usable capacity is segmented into fixed-size cells consisting of header and information fields, allocated to services on demand.

attribute byte

A byte of information, held in the directory entry of any file or folder, that describes various attributes of the file or folder, such as whether it is read-only or has been backed up since it last was changed. Attributes can be set by the DOS **ATTRIB** command or with Windows Explorer.

ATX

A motherboard and power supply form factor standard designed by Intel in 1995. It is characterized by a double row of rear external I/O connectors on the motherboard, a single keyed power supply connector, memory and processor locations that are designed not to interfere with the installation of adapter cards, and an improved cooling flow. The current specification ATX 2.0 was introduced in December 1996.

audio

A signal that can be heard, such as through the speaker of the PC. Many PC diagnostic tests use both visual (onscreen) codes and audio signals.

audio frequencies

Frequencies that can be heard by the human ear (approximately 20Hz-20,000Hz).

auto-answer

A setting in modems enabling them to answer incoming calls over the phone lines automatically.

auto-dial

A feature in modems enabling them to dial phone numbers without human intervention.

auto-disconnect

A modem feature that enables a modem to hang up the telephone line when the modem at the other end hangs up.

auto-redial

A modem or software feature that automatically redials the last number dialed if the number is busy

or does not answer.

AUTOEXEC. BAT

A special batch file DOS and Windows 9x execute at startup. Contains any number of DOS commands that are executed automatically, including the capability to start programs at startup. See also [batch file](#).

autoloader

A tape or Iomega REV-based drive that contains multiple media cartridges and a mechanism for removing and inserting cartridges as each cartridge is filled.

automatic head parking

Disk drive head parking performed whenever the drive is powered off. Found in all modern hard disk drives with a voice-coil actuator.

available memory

Memory currently not in use by the operating system, drivers, or applications, which can be used to load additional software.

average access time

The average time it takes a disk drive to begin reading any data placed anywhere on the drive. This includes the average seek time, which is when the heads are moved, as well as the latency, which is the average amount of time required for any given data sector to pass underneath the heads. Together, these factors make up the average access time. See also [average seek time](#) and [latency](#).

average latency

The average time required for any byte of data stored on a disk to rotate under the disk drive's read/write head. Equal to one-half the time required for a single rotation of a platter.

average seek time

The average amount of time it takes to move the heads from one random cylinder location to another, usually including any head settling time. In many cases, the average seek time is defined as the seek time across one-third of the total number of cylinders.

AVI (audio video interleave)

A storage technique developed by Microsoft for its Video for Windows product that combines audio and video into a single frame or track, saving valuable disk space and keeping audio in synchronization with the corresponding video. AVI files are widely supported by media players and video production programs.

AWG

American Wire Gauge, a U.S. standard for measuring the thickness of copper and aluminum wire for electrical and data-transmission use. Thinner wire is used to save space and for short distances, but thicker wire has less resistance and is better for long wire runs.

B Channel

The bearer channel in an ISDN network, it's used to carry data at a rate of 64KBps. See also [BRI](#).

backbone

The portion of the Internet or wide area network (WAN) transmission wiring that connects the main Internet/WAN servers and routers and is responsible for carrying the bulk of the Internet/WAN data.

backplane

A rarely used motherboard design in which the components typically found on a motherboard are instead located on an expansion adapter card plugged into a slot. In these systems, the board with the slots is the backplane. The PCI Industrial Computer Manufacturers Group (PICMG) single-board computer designs for rack-mount systems are the primary users of backplane designs today.

backup

The process of duplicating a file or library onto a separate piece of media. It's good insurance against the loss of an original. Depending on how the backup was made, the data might need to be restored with a special program before reuse.

backup disk

Contains information copied from another disk. Used to ensure that original information is not destroyed or altered.

backward compatibility

The design of software and hardware to work with previous versions of the same software or hardware.

bad sector

A disk sector that can't hold data reliably because of a media flaw or damaged format markings.

bad track table

A label affixed to the casing of an ST412/506 or ESDI hard disk drive that tells which tracks are

flawed and incapable of holding data. The listing is entered into the low-level formatting program. Modern ATA (IDE) and SCSI drives are low-level formatted during manufacture and don't have (or need) a bad track table.

balanced signal

Refers to signals consisting of equal currents moving in opposite directions. When balanced or nearly balanced signals pass through twisted-pair lines, the electromagnetic interference effects such as crosstalk caused by the two opposite currents largely cancel each other out. Differential signaling (used by some types of SCSI interfaces) is a method that uses balanced signals.

balun

Short for balanced/unbalanced. A type of transformer that enables balanced cables to be joined with unbalanced cables. Twisted-pair (balanced) cables, for example, can be joined with coaxial (unbalanced) cables if the proper balun transformer is used.

bandwidth

1) Generally, the measure of the range of frequencies within a radiation band required to transmit a particular signal. The difference between the lowest and highest signal frequencies. The bandwidth of a computer monitor is a measure of the rate at which a monitor can handle information from the display adapter. The wider the bandwidth, the more information the monitor can carry and the greater the resolution. 2) Used to describe the data-carrying capacity of a given communications circuit or pathway. The bandwidth of a circuit is a measure of the rate at which information can be passed.

bank

The collection of memory chips or modules that make up a block of memory readable or writable by the processor in a single cycle. This block, therefore, must be as large as the data bus of the particular microprocessor. In PC systems, the processor data bus (and therefore the bank size) is usually 8, 16, 32, or 64 bits wide. Optionally, some systems also incorporate an additional parity or ECC bit for each 8 data bits, resulting in a total of 9, 18, 36, or 72 bits (respectively) for each bank. Memory in a PC always must be added or removed in full-bank increments. The number of memory chips or modules that make up a bank varies with the width of the memory in bits and the size of the processor's data bus. For example, a K6-2 processor has a data bus that is 64 bits wide. If the motherboard uses 72-pin SIMMs (which are 32 data bits wide), a bank is two SIMMs. However, if the motherboard uses DIMMs, which are 64 data bits wide, a bank is one DIMM.

bar code

The code used on consumer products and inventory parts for identification purposes. Consists of bars of varying thickness that represent characters and numerals that are read with an optical reader. The most common version is called the universal product code (UPC).

base-2

Refers to the computer numbering system that consists of two numerals: 0 and 1. Also called binary.

base address

Starting location for a consecutive string of memory or I/O addresses/ports.

base memory

The amount of memory available to the operating system or application programs within the first megabyte, accessible in the processor's real mode.

baseband transmission

The transmission of digital signals over a limited distance. ARCnet and Ethernet local area networks use baseband signaling. Contrasts with broadband transmission, which refers to the transmission of analog signals over a greater distance.

BASIC (Beginner's All-purpose Symbolic Instruction Code)

A popular computer programming language originally developed by John Kemeny and Thomas Kurtz in the mid-1960s at Dartmouth College. Normally, BASIC is an interpretive language, meaning that each statement is translated and executed as it is encountered, but it can be a compiled language, in which all the program statements are compiled before execution. Microsoft Visual Basic, a popular development environment for Windows, is not related to BASIC.

batch file

A set of commands stored in a disk file for execution by the operating system. A special batch file called **AUTOEXEC. BAT** is executed by DOS each time the system is started. All DOS and Windows batch files have a .BAT file extension.

baud

A unit of signaling speed denoting the number of discrete signal elements that can be transmitted per second. The word baud is derived from the name of J.M.E. Baudot (1845-1903), a French pioneer in the field of printing telegraphy and the inventor of Baudot code. Although technically inaccurate, baud rate commonly is used to mean bit rate. Because each signal element or baud can translate into many individual bits, bits per second (bps) usually differs from baud rate. A rate of 2,400 baud means that 2,400 frequency or signal changes per second are being sent, but each frequency change can signal several bits of information. For example, 33.6Kbps modems actually transmit at only 2,400 baud.

Baudot code

A 5-bit code used in many types of data communications, including teletype (TTY), radio teletype (RTTY), and telecommunications devices for the deaf (TDD). Baudot code has been revised and extended several times. See also [baud](#).

bay

An opening in a computer case or chassis that holds disk drives.

BBS (bulletin board system)

A computer that operates with a program and a modem to enable other computers with modems to communicate with it, often on a round-the-clock basis. Although BBSs were once the primary means of distributing information and software, the Internet has almost completely replaced BBSs.

benchmark

A test or set of tests designed to compare the performance of hardware or software. A popular set of benchmarks for PC hardware is the *PC Magazine* benchmarks, such as Business Winstone, WinBench, and others. You can order CDs or download selected benchmarks from www.veritest.com/benchmarks/pcmbmk.asp.

bezel

A cosmetic panel that covers the face of a drive or some other device.

Bézier curve

A mathematical method for describing a curve, often used in illustration and CAD programs to draw complex shapes.

BGA (ball grid array)

A packaging technology used by Socket 478 Pentium 4 and Celeron processors, as well as many recent motherboard chipsets and video card memory chips. BGA uses small solder balls instead of pin connectors to enable more signaling paths to exist in a smaller space and improve signal accuracy.

bidirectional

- 1) Refers to lines over which data can move in two directions, such as a data bus or telephone line.
- 2) Refers to the capability of a printer to print from right to left and from left to right alternately.

binary

See [base-2](#).

BIOS (basic input/output system)

The part of an operating system that handles the communications between the computer and its peripherals. Often burned into read-only memory (ROM) chips or rewritable flash (EEPROM) memory

chips found on motherboards and expansion cards, such as video cards and SCSI and ATA/IDE host adapters. See also [firmware](#).

bipolar

A category of semiconductor circuit design that was used to create the first transistor and the first integrated circuit. Bipolar and CMOS are the two major transistor technologies. Almost all personal computers use CMOS technology chips. CMOS uses far less energy than bipolar.

bisynchronous (binary synchronous control)

An earlier protocol developed by IBM for software applications and communicating devices operating in synchronous environments. The protocol defines operations at the link level of communications for example, the format of data frames exchanged between modems over a phone line.

bit binary digit

Represented logically by 0 or 1 and electrically by 0 volts and (typically) 5 volts. Other methods are used to represent binary digits physically (tones, different voltages, lights, and so on), but the logic is always the same.

bit density

Expressed as bits per inch (BPI). Defines how many bits can be written onto one linear inch of a track. Sometimes also called linear density.

bit depth

The number of bits used to describe the color of each pixel on a computer display. For example, a bit depth of two (2^2) means the monitor can display only black and white pixels; a bit depth of four (2^4) means the monitor can display 16 different colors; a bit depth of eight (2^8) allows for 256 colors; and so on.

bitmap

A method of storing graphics information in memory, in which a bit devoted to each pixel (picture element) onscreen indicates whether that pixel is on or off. A bitmap contains a bit for each point or dot on a video display screen and enables fine resolution because any point or pixel onscreen can be addressed. A greater number of bits can be used to describe each pixel's color, intensity, and other display characteristics.

blade server

A thin circuit board that contains processors, memory, and (often) storage, which plugs into a special rack-mounted chassis. Multiple-blade servers can occupy a single chassis.

BladeCenter

A blade server design developed by IBM that might become the basis for a de facto blade architecture standard.

blank or blanking interval

A period in which no video signal is received by a monitor while the videodisc or digital video player searches for the next video segment or frame to display.

block

A string of records, words, or characters formed for technical or logic reasons and to be treated as an entity.

block diagram

The logical structure or layout of a system in graphics form. Does not necessarily match the physical layout and does not specify all the components and their interconnections.

Blue Book

The standard for enhanced CDs (CD-E). CD-E media contains both music (for play on standard CD players) and computer content. Developed by Philips and Sony in 1995.

blue screen of death

A system crash in Windows that replaces the normal desktop with a blue screen with white text reporting the problem and locks up the system. Also referred to as a BSOD, this condition can be triggered by defective memory, file system errors, and other system problems.

Bluetooth

An emerging short-range networking standard, Bluetooth is designed to enable PCs, mobile phones, input devices, and PDAs to exchange data with each other. Bluetooth uses the same 2.4GHz frequency range used by some types of wireless phones and by the IEEE 802.11b Wi-Fi wireless Ethernet network. Bluetooth has a speed of 1Mbps or 2Mbps, depending on the version.

BMP

A Windows graphics format that can be device dependent or independent. Device-independent BMP files (DIB) are coded for translation to a wide variety of displays and printers.

BNC (Bayonet-Neill-Concelman)

Also known as British-Naval-Connector, Baby-N-Connector, or Bayonet-Nut-Coupler, this bayonet-locking connector is noted for its excellent shielding and impedance-matching characteristics, resulting in low noise and minimal signal loss at any frequency up to 4GHz. It is used in Ethernet

10BASE-2 networks (also known as IEEE 802.3 or Thinnet) to terminate coaxial cables. It is also used for some high-end video monitors. BNC is named for its connection type (bayonet) and its co-developers.

bonding

In ISDN, joining two 64Kbps B-channels to achieve 128Kbps speed. Bonding can also be used with analog modems that use the Multilink Point-to-Point protocol that is supported by Windows 98 and newer versions but by only a few ISPs.

Boolean operation

Any operation in which each of the operands and the result take one of two values. A Boolean search can be performed with many search engines used on websites and help files using operators such as **AND**, **OR**, and **NOT**.

boot

To load a program into the computer. The term comes from the phrase "pulling a boot on by the bootstrap."

boot manager

A program that enables you to select which active partition to boot from. Often supplied with aftermarket disk-partitioning programs, such as PartitionMagic, or installed by default when you install a Windows upgrade into a separate disk partition instead of replacing your old version. See also [active partition](#).

boot record

The first sector on a disk or partition that contains disk parameter information for the BIOS and operating system as well as bootstrap loader code that instructs the system how to load the operating system files into memory, thus beginning the initial boot sequence to boot the machine.

boot sector

See [boot record](#).

boot sector virus

A virus designed to occupy the boot sector of a disk. Any attempt to start or boot a system from this disk transfers the virus to the hard disk, after which it subsequently is loaded every time the system is started. Many older PC viruses, particularly those spread by infected floppy disks, are boot sector viruses.

bootstrap

A technique or device designed to bring itself into a desired state by means of its own action. The term is used to describe the process by which a device such as a PC goes from its initial power-on condition to a running condition without human intervention. See also [boot](#).

boule

Purified, cylindrical silicon crystals from which semiconducting electronic chips, including microprocessors, memory, and other chips, in a PC are manufactured. Also called an ingot.

bps (bits per second)

The number of binary digits, or bits, transmitted per second. Sometimes confused with baud.

branch prediction

A feature of fifth-generation (Pentium and higher) processors that attempts to predict whether a program branch will be taken and then fetches the appropriate following instructions.

BRI

Short for basic rate interface, it's a form of ISDN used in home and small business applications. A 2B +1D BRI service has two B channels and a single D channel for signaling and control uses.

bridge

In local area networks, an interconnection between two similar networks. Also the hardware equipment used to establish such an interconnection.

broadband transmission

A term used to describe analog transmission. Requires modems for connecting terminals and computers to the network. Using frequency division multiplexing, many signals or sets of data can be transmitted simultaneously. The alternative transmission scheme is baseband, or digital, transmission.

brownout

An AC supply voltage drop in which the power does not shut off entirely but continues to be supplied at lower-than-normal levels.

BSOD

See [blue screen of death](#).

BTX

Short for Balanced Technology Extended, a PC and server architecture introduced by Intel in September 2003. BTX is designed to improve internal cooling by placing memory and processors in line with cooling fans.

bubble memory

A special type of nonvolatile read/write memory introduced by Intel in which magnetic regions are suspended in crystal film and data is maintained when the power is off. A typical bubble memory chip contains about 512KB, or more than four million bubbles. Bubble memory failed to catch on because of slow access times measured in several milliseconds. It has, however, found a niche use as solid-state "disk" emulators in environments in which conventional drives are unacceptable, such as in military or factory use.

buffer

A block of memory used as a holding tank to store data temporarily. Often positioned between a slower peripheral device and the faster computer. All data moving between the peripheral and the computer passes through the buffer. A buffer enables the data to be read from or written to the peripheral in larger chunks, which improves performance. A buffer that is x bytes in size usually holds the last x bytes of data that moved between the peripheral and CPU. This method contrasts with that of a cache, which adds intelligence to the buffer so that the most often accessed data, rather than the last accessed data, remains in the buffer (cache). A cache can improve performance greatly over a plain buffer.

bug

An error or a defect in a program; it can be corrected through program patches (for applications or operating systems) or firmware updates (for BIOS chips).

burn-in

The operation of a circuit or equipment to establish that its components are stable and to screen out defective parts or assemblies.

BURN-Proof

Short for buffer underrun error-proof, it's a technology developed by Sanyo to prevent buffer underruns during the creation of CD-Rs. BURN-Proof, which has been licensed to many CD-RW drive makers, enables a drive to pause the burning process and continue after sufficient data is available in the drive's buffer. The drive and CD-mastering software must both support BURN-Proof for this feature to work. Ricoh's JustLink works in a similar fashion. See also [lossless linking](#).

burst mode

A memory-cycling technology that takes advantage of the fact that most memory accesses are consecutive in nature. After setting up the row and column addresses for a given access, using burst mode can then access the next three adjacent addresses with no additional latency.

Burst Static RAMs (BSRAMs)

Short for Pipeline Burst SRAM, BSRAMs are a common type of static RAM chip used for memory caches where access to subsequent memory locations after the first byte is accessed takes fewer machine cycles.

bus

A linear electrical signal pathway over which power, data, and other signals travel. It is capable of connecting to three or more attachments. A bus is generally considered to be distinct from radial or point-to-point signal connections. The term comes from the Latin *omnibus*, meaning "for all." When used to describe a topology, bus always implies a linear structure.

bus mouse

An obsolete type of mouse used in the 1980s that plugs into a special mouse expansion board (occasionally incorporated into a video card) instead of a serial port or motherboard mouse port. The bus mouse connector looks similar to a motherboard mouse (sometimes called PS/2 mouse) connector, but the pin configurations are different and not compatible.

busmaster

An intelligent device that, when attached to the Micro Channel, EISA, VLB, or PCI bus, can bid for and gain control of the bus to perform its specific task without processor intervention. Most recent motherboards incorporate busmastering ATA/IDE host adapters, but this feature must be enabled in both the BIOS and through the installation of Windows drivers to be effective.

byte

A collection of bits that makes up a character or other designation. Generally, a byte is 8 data bits. When referring to system RAM, an additional parity (error-checking) bit is also stored (see [parity](#)), making the total 9 bits.

C

A high-level computer programming language. A programming language frequently used on mainframes, minis, and PC computer systems. C++ is a popular variant.

C3

A Socket 370-compatible processor developed by VIA Technology from the Cyrix "Joshua" after VIA purchased Cyrix from National Semiconductor. The C3 is noted for its very small die size and cool operation, making it a suitable choice for portable computers and embedded computers.

CAB file

Short for cabinet file, the archive file type used by Microsoft to distribute recent versions of Windows and applications. Some recent versions of WinZip can be used to manually extract files from a CAB

file; you can also open CAB files within Windows Explorer with Windows 98 after you install the Windows 98 Plus! package and with Windows Explorer in Windows 2000, Windows Me, and Windows XP.

cable modem

A broadband Internet device that receives data through the cable TV system. The cable modem can be a one-way device (using a conventional analog modem for dialing and uploading) or a two-way device.

CableLabs Certified Cable Modem

A cable modem that meets the Data or Cable Service Interface Specifications (DOCSIS) standards for modulation and protocols. Various brands and models of modems meet this standard on cable networks that also meet this standard. DOCSIS/CableLabs Certified Cable Modems can be purchased as well as leased.

cache

An intelligent buffer. By using an intelligent algorithm, a cache contains the data accessed most often between a slower peripheral device and the faster CPU. See also [L1 cache](#), [L2 cache](#), and [disk cache](#).

cache coherency

A method of managing processor caches in multiprocessor systems to ensure that data is not lost when it is moved from cache to main memory.

caddy

A cartridge designed to hold a CD or DVD disc. Some CD drives use caddies, particularly in harsh or industrial environments. DVD-RAM drives also use a caddy to protect the disc.

CAM (Common Access Method)

A committee formed in 1988 that consists of several computer peripheral suppliers and is dedicated to developing standards for a common software interface between SCSI peripherals and host adapters.

candela

Abbreviated cd, a candela is the standard unit of measurement for luminosity. The brightness of LCDs and other types of displays is sometimes measured in cd units.

capacitor

A device consisting of two plates separated by insulating material and designed to store an electrical

charge.

card

A printed circuit board containing electronic components that form an entire circuit, usually designed to plug into a connector or slot. Sometimes also called an adapter.

card edge connector

See [edge connector](#).

CardBus

A PC Card (PCMCIA) specification for a 32-bit interface that runs at 33MHz and provides 32-bit data paths to the computer's I/O and memory systems, as well as a new shielded connector that prevents CardBus devices from being inserted into slots that do not support the latest version of the PC Card (PCMCIA) standard. CardBus slots can also be used with normal 16-bit PC Card (PCMCIA) devices.

carpal tunnel syndrome

A painful hand injury that gets its name from the narrow tunnel in the wrist that connects ligament and bone. When undue pressure is put on the tendons, they can swell and compress the median nerve, which carries impulses from the brain to the hand, causing numbness, weakness, tingling, and burning in the fingers and hands. Computer users get carpal tunnel syndrome primarily from improper keyboard ergonomics that result in undue strain on the wrist and hand.

carrier

A continuous frequency signal capable of being either modulated or impressed with another information-carrying signal. The reference signal used for the transmission or reception of data. The most common use of this signal with computers involves modem communications over phone lines. The carrier is used as a signal on which the information is superimposed.

carrier detect signal

A modem interface signal that indicates to the attached data terminal equipment (DTE) that it is receiving a signal from the distant modem. Defined in the RS-232 specification. Same as the received line-signal detector.

CAT

Short for category, it describes the ANSI/EIA 568 wiring standards used for data transmission. The most common CAT standards include CAT 3 (16Mbps maximum data rate, suitable for 10BASE-T Ethernet) and CAT 5 (used for 100BASE-T Fast Ethernet or 1000BASE-T Gigabit Ethernet).

cathode ray tube (CRT)

A device that contains electrodes surrounded by a glass sphere or cylinder and displays information by creating a beam of electrons that strike a phosphor coating inside the display unit. This device is most commonly used in computer monitors and terminals.

CAV (constant angular velocity)

An optical disk recording format in which the data is recorded on the disk in concentric circles. CAV disks are rotated at a constant speed. This is similar to the recording technique used on floppy disk drives. CAV limits the total recorded capacity compared to CLV (constant linear velocity), which also is used in optical recording. See also [CLV](#).

CCITT

An acronym for the Comité Consultatif International de Télégraphique et Téléphonique (in English, the International Telegraph and Telephone Consultative Committee or the Consultative Committee for International Telegraph and Telephone). Renamed ITU (International Telecommunications Union). See also [ITU](#).

CCS (common command set)

A set of SCSI commands specified in the ANSI SCSI-1 Standard X3.131-1986 Addendum 4.B. All SCSI devices must be capable of using the CCS to be fully compatible with the ANSI SCSI-1 standard.

CD (compact disc or compact audio disc)

A 4.75" (12cm) optical disc that contains information encoded digitally in the constant linear velocity (CLV) format. This popular format for high-fidelity music offers 90 decibels signal/noise ratio, 74 minutes of digital sound, and no degradation of quality from playback. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Red Book. The official (and rarely used) designation for the audio-only format is CD-DA (compact disc-digital audio). The simple audio format is also known as CD-A (compact disc-audio). A smaller (3") version of the CD is known as CD-3.

CD burner

Refers to either a CD-R or CD-RW drive. See also [DVD burner](#).

CD+G (Compact Disc+Graphics)

A CD format that includes extended graphics capabilities as written into the original CD-ROM specifications. Includes limited video graphics encoded into the CD subcode area. Originally developed and marketed by Warner New Media (later Time Warner Interactive), it's a popular choice for self-contained karaoke systems.

CD-I (Compact Disc-Interactive)

A compact disc format released in October 1991 that provides audio, digital data, still graphics, and motion video. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Green Book. CD-I did not catch on with consumers and is now considered obsolete.

CD+MIDI (Compact Disc+Musical Instrument Digital Interface)

A CD format that adds to the CD+G format digital audio, graphics information, and musical instrument digital interface (MIDI) specifications and capabilities. Originally developed and marketed by Warner New Media (later Time Warner Interactive).

CD-R (Compact Disc-Recordable, sometimes called CD-writable)

CD-R discs are compact discs that can be recorded and read as many times as desired. CD-R is part of the Orange Book standard defined by ISO. CD-R technology is used for mass production of multimedia applications. CD-R discs can be compatible with CD-ROM, CD-ROM XA, and CD audio. Orange Book specifies multisession capabilities, which enable data recording on the disc at various times in several recording sessions. Multisession capability enables data such as digital photos, digital music, or other types of data files to be added to a single disc on different occasions. The original capacity of CD-R media was 650MB (74 minutes), but most recent CD-ROM and compatible optical drives support the larger 700MB (80-minute) media.

CD-ROM (compact disc-read-only memory)

A 4.75" laser-encoded optical memory storage medium with the same constant linear velocity (CLV) spiral format as audio CDs and some videodiscs. CD-ROMs can hold about 650MB of data and require more error-correction information than the standard prerecorded compact audio discs. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Yellow Book. See also [CD-ROM XA](#).

CD-ROM drive

A device that retrieves data from a CD-ROM disc; it differs from a standard audio CD player by the incorporation of additional error-correction circuitry. CD-ROM drives usually can also play music from audio CDs.

CD-ROM XA (compact disc-read-only memory extended architecture)

The XA standard was developed jointly by Sony, Philips, and Microsoft in 1988 and is now part of the Yellow Book standard. XA is a built-in feature of newer CD-ROM drives and supports simultaneous sound playback with data transfer. Non-XA drives support either sound playback or data transfer, but not both simultaneously. XA also enables data compression right on the disk, which also can increase data transfer rates.

CD-RW (compact disc-rewritable)

A type of rewritable CD-ROM technology defined in Part III of the Orange Book standard that uses a different type of disc, which the drive can rewrite at least 1,000 times. CD-RW drives also can be used to write CD-R discs, and they can read CD-ROMs. CD-RWs have a lower reflectivity than standard CD-ROMs, and CD-ROM drives must be of the newer multiread variety to read them. CD-

RW was initially known as CD-E (for CD-erasable).

CD Video

A CD format introduced in 1987 that combines 20 minutes of digital audio and 6 minutes of analog video on a standard 4.75" CD. Upon introduction, many firms renamed 8" and 12" videodiscs CDV in an attempt to capitalize on the consumer popularity of the audio CD. The term fell out of use in 1990 and was replaced in some part by "laser disc" and, more recently, "DVD." See also [video-on-CD](#).

CD-WO (compact disc-write once)

A variant on CD-ROM that can be written to once and read many times; developed by NV Philips and Sony Corporation. Also known as CD-WORM (CD-write once/read many), CD-recordable, or CD-writable. Standards for this format are known as the Orange Book.

CD-WORM

See [CD-WO](#).

CDMA

Short for code division multiple access, a popular family of wireless protocols used in cellular phones for Internet and email access.

CEB

Short for Compact Electronics Bay, this is an SSI form factor for rack-mounted servers. See also [SSI](#).

Celeron

A family of processors that are low-cost versions of the Pentium II, Pentium III, and Pentium 4 processors. The major differences include a smaller amount of L2 cache and lower clock speeds.

Centronics connector

Refers to one of two types of cable connectors used with either parallel (36-pin edge connector) or SCSI (50-pin edge connector) devices.

ceramic substrate

A thin, flat, fired-ceramic part used to hold an IC chip (usually made of beryllium oxide or aluminum oxide).

CERN (Conseil Européen pour la Recherche Nucléaire; The European Laboratory for Particle Physics)

The site in Geneva where the World Wide Web was created in 1989.

CGA (color graphics adapter)

A type of PC video display adapter introduced by IBM on August 12, 1981, which supports text and graphics. Text is supported at a maximum resolution of 80x25 characters in 16 colors with a character box of 8x8 pixels. Graphics are supported at a maximum resolution of 320x200 pixels in 16 colors or 640x200 pixels in 2 colors. The CGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz and supports TTL color or NTSC composite displays.

channel

1) Any path along which signals can be sent. 2) In ISDN, data bandwidth is divided into two B-channels that bear data and one D-channel that carries information about the call.

character

A representation coded in binary digits of a letter, number, or other symbol.

character set

All the letters, numbers, and characters a computer can use to represent data. The ASCII standard has 256 characters, each represented by a binary number from 1 to 256. The ASCII set includes all the letters in the alphabet, numbers, most punctuation marks, some mathematical symbols, and other characters.

charge coupled device

A light-sensing and storage device used in scanners and digital cameras to capture the pixels.

chassis

The case used by a desktop PC or server. A server platform includes a chassis, a motherboard, processor(s), and other components.

check bit

See [*parity*](#).

checksum

Short for *summation check*, a technique for determining whether a package of data is valid. The package, a string of binary digits, is added up and compared with the expected number.

chip

Another name for an IC, or integrated circuit. Housed in a plastic or ceramic carrier device with pins for making electrical connections.

chip carrier

A ceramic or plastic package that carries an integrated circuit.

chipkill

An advanced form of ECC memory correction that can correct multiple-bit failures in a single memory module. Also known as Advanced ECC. See also [ECC](#).

chipset

A single chip or pair of chips that integrates into the clock generator, bus controller, system timer, interrupt controller, DMA controller, CMOS RAM/clock, and keyboard controller. See also [North Bridge](#) and [South Bridge](#).

CHS (cylinder head sector)

The term used to describe the nontranslating scheme used by the BIOS to access IDE drives that are less than or equal to 528MB in capacity. See also [LBA](#).

CIF (common image format)

The standard sample structure that represents the picture information of a single frame in digital HDTV, independent of frame rate and sync/blank structure. The uncompressed bit rate for transmitting CIF at 29.97 frames/sec is 36.45Mbps.

CIOB

One of a series of I/O bridge chips used by the Broadcom ServerWorks series of server chipsets.

circuit

A complete electronic path.

circuit board

The collection of circuits gathered on a sheet of plastic, usually with all contacts made through a strip of pins. The circuit board usually is made by chemically etching metal-coated plastic.

CISC (complex instruction set computer)

Refers to traditional computers that operate with large sets of processor instructions. Most modern computers, including the Intel 80xxx processors, are in this category. CISC processors have expanded instruction sets that are complex in nature and require several to many execution cycles to complete. This structure contrasts with RISC (reduced instruction set computer) processors, which have far fewer instructions that execute quickly.

clean room

1) A dust-free room in which certain electronic components (such as chips or hard disk drives) must be manufactured and serviced to prevent contamination. Rooms are rated by Class numbers. A Class 100 clean room must have fewer than 100 particles larger than 0.5 microns per cubic foot of space. 2) A legal approach to copying software or hardware in which one team analyzes the product and writes a detailed description, followed by a second team who reads the description written by the first and then develops a compatible version of the product. When done correctly, such a design methodology will survive a legal attack.

client/server

A type of network in which every computer is either a server with a defined role of sharing resources with clients or a client that can access the resources on the server.

clock

The source of a computer's timing signals. It synchronizes every operation of the CPU.

clock multiplier

A processor feature where the internal core runs at a higher speed than the motherboard or processor bus. See also [overclocking](#).

clock speed

A measurement of the rate at which the clock signal for a device oscillates, usually expressed in millions of cycles per second (MHz).

clone

Originally referred to an IBM-compatible computer system that physically as well as electrically emulates the design of one of IBM's personal computer systems. More currently, it refers to any PC system running an Intel or compatible processor in the 80x86 family.

cluster

Also called *allocation unit*. A group of one or more sectors on a disk that forms a fundamental unit of storage to the operating system. Cluster, or allocation unit, size is determined by the operating system when the disk is formatted. Larger clusters generally offer faster system performance but waste disk space.

CLV (constant linear velocity)

An optical recording format in which the spacing of data is consistent throughout the disk and the rotational speed of the disk varies depending on which track is being read. Additionally, more sectors of data are placed on the outer tracks compared to the inner tracks of the disk, which is similar to zone recording on hard drives. CLV drives adjust the rotational speed to maintain a constant track velocity as the diameter of the track changes. CLV drives also rotate more quickly near the center of the disk and more slowly toward the edge. Rotational adjustment maximizes the amount of data that can be stored on a disk. CD audio and CD-ROM use CLV recording. See also [CAV](#).

CMOS (complementary metal-oxide semiconductor)

A type of chip design that requires little power to operate. In PCs, a battery-powered CMOS memory and clock chip is used to store and maintain the clock setting and system configuration information.

CMYK (cyan magenta yellow black)

The standard four-color model used for printing.

CNR

Short for Communications and Networking Riser, it was developed by Intel as a replacement for the AMR. CNR enables motherboard makers to offer low-cost modem, networking, and audio features through a special expansion slot. Unlike AMR, a CNR slot can be built as a shared slot with a PCI slot. See also [AMR](#).

coated media

Hard disk platters coated with a reddish iron-oxide medium on which data is recorded.

coaxial cable

Also called *coax cable*. A data-transmission medium noted for its wide bandwidth, immunity to interference, and high cost compared to other types of cable. Signals are transmitted inside a fully shielded environment, in which an inner conductor is surrounded by a solid insulating material and then an outer conductor or shield. Used in many local area network systems, such as Ethernet and ARCnet.

COBOL (Common Business-Oriented Language)

A high-level computer programming language used primarily by some larger companies. It has never achieved popularity on personal and small business computers.

code page

A table used in DOS 3.3 and later that sets up the keyboard and display characters for various

foreign languages.

code page switching

A DOS feature in versions 3.3 and later that changes the characters displayed onscreen or printed on an output device. Primarily used to support foreign-language characters. Requires an EGA or better video system and an IBM-compatible graphics printer.

CODEC (coder-decoder)

A device that converts voice signals from their analog form to digital signals acceptable to more modern digital PBXs and digital transmission systems. It then converts those digital signals back to analog so you can hear and understand what the other party is saying. Also refers to compression/decompression software used in the creation of digital audio and video files, such as MP3 and MPEG, and for videophone programs.

coercivity

A measurement in units of oersteds of the amount of magnetic energy to switch or "coerce" the flux change in the magnetic recording media. High-coercivity disk media require a stronger write current.

cold boot

The act of starting or restarting a computer from a powered-off state. If the system is on, this requires cycling the power off and then back on. A cold boot causes all RAM to be forcibly cleared. See also [warm boot](#).

collision

In a LAN, if two computers transmit a packet of data at the same time on the network, the data can become garbled, which is known as a collision.

collision detection/avoidance

A process used on a LAN to prevent data packets from interfering with each other and to determine whether data packets have encountered a collision and initiate a resend of the affected packets.

color graphics adapter

See [CGA](#).

color palette

The colors available to a graphics adapter for display.

COM port

A serial port on a PC that conforms to the RS-232 standard. See also [RS-232](#).

COMDEX

The largest international computer trade show and conference in the world, managed by MediaLive International, Inc. See www.comdex.com for the latest information.

command

An instruction that tells the computer to start, stop, or continue an operation.

COMMAND.COM

An operating system file that is loaded last when the computer is booted. The command interpreter or user interface and program-loader portion of DOS.

command interpreter

The operating system program that controls a computer's shell or user interface. The command interpreter for MS-DOS (and the command-line sessions in Windows 9x/Me) is **COMMAND.COM**; the command interpreter for the graphical shell in Windows versions through 9x/Me is **WIN.COM**; the command interpreter for NT-based versions of Windows (including Windows 2000 and Windows XP) is **CMD.COM**.

common

The ground or return path for an electrical signal. If it's a wire, it usually is colored black.

common mode noise

Noise or electrical disturbances that can be measured between a current- or signal-carrying line and its associated ground. Common mode noise is frequently introduced to signals between separate computer equipment components through the power distribution circuits. It can be a problem when single-ended signals are used to connect different equipment or components that are powered by different circuits.

CompactFlash

An ATA flash memory card physical format approximately one third the size of a standard PC Card. Often abbreviated CF or CF+, CompactFlash cards are identical in function to standard ATA Flash PC Cards (PCMCIA) but use 50 pin connectors instead of 68. ATA flash cards contain built-in disk controller circuitry to enable the card to function as a solid-state disk drive. CF cards can plug into a CompactFlash socket or with an adapter into a standard Type I or II PC Card (PCMCIA) slot. CF cards are used by many types of digital cameras.

CompactPCI

The PICMG standard for PCI-based industrial computers, CompactPCI boards plug into a 220-pin IEC-1076 bus.

compatible

1) In the early days of the PC industry when IBM dominated the market, a term used to refer to computers from other manufacturers that had the same features as a given IBM model. 2) In general, software or hardware that conforms to industry standards or other de facto standards so that it can be used in conjunction with or in lieu of other versions of software or hardware from other vendors in a like manner.

compiler

A program that translates a program written in a high-level language into its equivalent machine language. The output from a compiler is called an object program.

complete backup

A backup of all information on a hard disk, including the directory tree structure.

composite video

Television picture information and sync pulses combined. The complete wave form of the color video signal composed of chrominance and luminance picture information; blanking pedestal; field, line, and color-sync pulses; and field-equalizing pulses. Some video cards have an RCA jack that outputs a composite video signal. See also [RGB](#).

compressed file

A file that has been reduced in size via one or more compression techniques. See also [archive file](#).

computer

Device capable of accepting data, applying prescribed processes to this data, and displaying the results or information produced.

computer-based training (CBT)

The use of a computer to deliver instruction or training; also known as computer-aided (or assisted) instruction (CAI), computer-aided learning (CAL), computer-based instruction (CBI), and computer-based learning (CBL).

CONFIG.SYS

A file that can be created to tell DOS how to configure itself when the machine starts up. It can load device drivers, set the number of DOS buffers, and so on.

configuration file

A file kept by application software to record various aspects of the software's configuration, such as the printer it uses. Windows uses **.INI** files and the Windows Registry to control its configuration.

console

The unit, such as a terminal or a keyboard, in your system with which you communicate with the computer.

contiguous

Touching or joined at the edge or boundary, in one piece.

continuity

In electronics, an unbroken pathway. Testing for continuity usually means testing to determine whether a wire or other conductor is complete and unbroken (by measuring 0 ohms). A broken wire shows infinite resistance (or infinite ohms).

control cable

The wider of the two cables that connect an ST-506/412 or ESDI hard disk drive to a controller card. A 34-pin cable that carries commands and acknowledgments between the drive and controller.

controller

The electronics that control a device, such as a hard disk drive, and intermediate the passage of data between the device and computer.

controller card

An adapter holding the control electronics for one or more devices, such as hard disks. Ordinarily occupies one of the computer's slots.

conventional memory

The first megabyte or first 640KB of system memory accessible by an Intel processor in real mode. Sometimes called base memory.

convergence

Describes the capability of a color monitor to focus the three colored electron beams on a single point. Poor convergence causes the characters onscreen to appear fuzzy and can cause headaches and eyestrain.

coprocessor

An additional computer processing unit designed to handle specific tasks in conjunction with the main or central processing unit.

copy protection

A hardware or software scheme to prohibit making illegal copies of a program.

core

An old-fashioned term for computer memory.

core speed

The internal speed of a processor. With all modern processors, this speed is faster than the system bus speed, and that speed relationship is regulated by the clock multiplier in the processor.

CP/M (Control Program for Microcomputers, originally Control Program/Monitor)

An operating system created by Gary Kildall, the founder of Digital Research. Created for the old 8-bit microcomputers that used the 8080, 8085, and Z-80 microprocessors. It was the dominant operating system in the late 1970s and early 1980s for small computers used in business environments.

cps (characters per second)

A data transfer rate generally estimated from the bit rate and character length. At 2,400bps, for example, 8-bit characters with start and stop bits (for a total of 10 bits per character) are transmitted at a rate of approximately 240cps. Some protocols, such as V.42 and MNP, employ advanced techniques such as longer transmission frames and data compression to increase characters per second.

CPU (central processing unit)

The computer's microprocessor chip; the brains of the outfit. Typically, an IC using VLSI (very-large-scale integration) technology to pack several functions into a tiny area. The most common electronic device in the CPU is the transistor, of which several thousand to several million or more are found.

crash

A malfunction that brings work to a halt. A system crash usually is caused by a software malfunction, and ordinarily you can restart the system by rebooting the machine. A head crash, however, entails physical damage to a disk and probable data loss.

CRC (cyclic redundancy checking)

An error-detection technique consisting of a cyclic algorithm performed on each block or frame of data by both sending and receiving modems. The sending modem inserts the results of its computation in each data block in the form of a CRC code. The receiving modem compares its results with the received CRC code and responds with either a positive or negative acknowledgment. In the ARQ protocol implemented in high-speed modems, the receiving modem accepts no more data until a defective block is received correctly.

crossbar

A type of memory controller that interchanges data between different memory paths. It's used in some server chipsets and advanced graphics processors.

crosstalk

The electromagnetic coupling of a signal on one line with another nearby signal line. Crosstalk is caused by electromagnetic induction, where a signal traveling through a wire creates a magnetic field that induces a current in other nearby wires. Various methods including twisting wire pairs and placing ground wires between data wires are used to combat crosstalk and create more reliable data communications.

CRT (cathode-ray tube)

A term used to describe a television or monitor screen tube.

current

The flow of electrons, measured in amperes, or amps.

cursor

The small, flashing hyphen that appears onscreen to indicate the point at which any input from the keyboard will be placed.

cycle

Time for a signal to transition from one leading edge to the next leading edge.

cyclic redundancy checking

See [CRC](#).

cylinder

The set of tracks on a disk that are on each side of all the disk platters in a stack and are the same

distance from the center of the disk. The total number of tracks that can be read without moving the heads. A floppy drive with two heads usually has 160 tracks, which are accessible as 80 cylinders. A typical 120GB hard disk will physically have about 56,000 cylinders, 6 heads (3 platters), and an average of about 700 sectors per track, for a total of about 235,200,000 sectors (120.4GB).

Cyrix

Originally a Texas-based maker of Intel-compatible math coprocessor chips, Cyrix later developed low-cost, plug-compatible 6x86 and 6x86MX Pentium-class processors that were manufactured by IBM and other fabricators. Cyrix also developed the first chipsets with integrated audio and video (the MediaGX series). Cyrix was later absorbed into National Semiconductor, which retained the MediaGX technology when it sold Cyrix to VIA Technologies. VIA formerly developed and sold the VIA Cyrix MII, a low-cost Super Socket 7 processor, and currently sells and develops the C3, developed from the Cyrix "Joshua" processor. See also [C3](#) and [VIA Technologies](#).

D/A converter (DAC)

A device that converts digital signals to analog form. See also [RAMDAC](#).

D-channel

In ISDN, a 16Kbps channel used to transmit control data about a connection.

daisy-chain

Stringing up components in such a manner that the signals move serially from one to the other. Most microcomputer multiple disk drive systems are daisy-chained. The SCSI bus system is a daisy-chain arrangement, in which the signals move from computer to disk drives to tape units, and so on. USB and IEEE-1394 devices also use the daisy-chain arrangement when hubs are used.

daisywheel printer

An impact printer that prints fully formed characters one at a time by rotating a circular print element composed of a series of individual spokes, each containing two characters that radiate from a center hub. Produces letter-quality output but has long been replaced by laser and LED printers.

DAT (digital audio tape)

A small cassette containing 4mm-wide tape used for storing large amounts of digital information. DAT technology emerged in Europe and Japan in 1986 as a way to produce high-quality, digital audio recordings and was modified in 1988 to conform to the digital data storage (DDS) standard for storing computer data. Raw/2:1 compressed capacities for a single tape are 2/4GB for DDS, 4/8GB for DDS-2, 12/24GB for DDS-3, 20/40GB for DDS-4, and 36/72GB for DAT 72 (the latest standard).

data

1) Groups of facts processed into information. A graphic or textural representation of facts, concepts, numbers, letters, symbols, or instructions used for communication or processing. 2) An android from the twenty-fourth century with a processing speed of 60 trillion operations per second and a storage capacity of 800 quadrillion bits, and who serves on the USS Enterprise NCC-1701-D with the rank of lieutenant commander.

data bus

The connection that transmits data between the processor and the rest of the system. The width of the data bus defines the number of data bits that can be moved into or out of the processor in one cycle.

data cable

Generically, a cable that carries data. Specific to HD connections, the narrower (20-pin) of two cables that connects an ST-506/412 or ESDI hard disk drive to a controller card.

data communications

A type of communication in which computers and terminals can exchange data over an electronic medium.

data compression

A technique in which mathematical algorithms are applied to the data in a file to eliminate redundancies and therefore reduce the size of the file. See also [lossless compression](#) and [lossy compression](#).

Data Link Layer

In networking, the layer of the OSI reference model that controls how the electrical impulses enter or leave the network cable. Ethernet and Token-Ring are the two most common examples of Data Link Layer protocols. See also [OSI](#).

data separator

A device that separates data and clock signals from a single encoded signal pattern. Usually, the same device performs both data separation and combination and is sometimes called an endec, or encoder/decoder.

data transfer rate

The maximum rate at which data can be transferred from one device to another.

daughterboard

Add-on board to increase functionality and/or memory. Attaches to the existing board.

DB-9

9-pin D-shell connector, primarily used for PC serial ports.

DB-25

25-pin D-shell connector, primarily used for PC parallel ports.

DC

Direct current, such as that provided by a power supply or batteries.

DC-600 (Data Cartridge 600)

A data-storage medium invented by 3M in 1971 that uses a 1/4"-wide tape 600 feet in length.

DCE (data communications equipment)

The hardware that performs communication usually a dialup modem that establishes and controls the data link through the telephone network. See also [DTE](#).

DDE (dynamic data exchange)

A form of interprocess communications used by Microsoft Windows to support the exchange of commands and data between two applications running simultaneously. This capability has been enhanced further with object linking and embedding (OLE).

DDoS (distributed denial of service)

Refers to a type of denial-of-service attack that uses multiple computers that have been taken over by an intruder to attack a targeted system. See also [DoS](#).

DDR (double data rate)

A type of SDRAM that allows two accesses per clock cycle, doubling the effective speed of the memory. The most common types of DDR include PC2100 (also known as DDR 266MHz), PC2700 (also known as DDR 333MHz) and PC3200 (also known as DDR 400MHz). See also [SDRAM](#).

DDR2 (double data rate 2)

A type of SDRAM that enables two accesses per clock cycle, doubling the effective speed of the memory. DDR2 has more robust signaling and is faster than conventional DDR. The most common types of DDR2 include PC2-3200 (also known as DDR2-400MHz), PC2-4300 (also known as DDR2-533MHz), PC2-5400 (also known as DDR2-667MHz), and PC2-6400 (also known as DDR2-800MHz).

See also [DDR](#) and [SDRAM](#).

de facto standard

A software or hardware technology not officially made a standard by any recognized standards organization but that is used as a reference for consumers and vendors because of its dominance in the marketplace.

DEBUG

The name of a utility program included with DOS and used for specialized purposes, such as altering memory locations, tracing program execution, patching programs and disk sectors, and performing other low-level tasks.

decibel (dB)

A logarithmic measure of the ratio between two powers, voltages, currents, sound intensities, and so on. Signal-to-noise ratios are expressed in decibels.

dedicated line

A user-installed telephone line that connects a specified number of computers or terminals within a limited area, such as a single building. The line is a cable rather than a public-access telephone line. The communications channel also can be referred to as nonswitched because calls do not go through telephone company switching equipment.

dedicated servo surface

In voice-coilactuated hard disk drives, one side of one platter given over to servo data that is used to guide and position the read/write heads.

default

Any setting assumed at startup or reset by the computer's software and attached devices and operational until changed by the user. An assumption the computer makes when no other parameters are specified. When you type DIR without specifying the drive to search, for example, the computer assumes you want it to search the default drive. The term is used in software to describe any action the computer or program takes on its own with embedded values.

defect map

A list of unusable sectors and tracks coded onto a drive during the low-level format process.

defragmentation

The process of rearranging disk sectors so files are stored on consecutive sectors in adjacent tracks.

degauss

1) To remove magnetic charges or to erase magnetic images. Normal applications include CRT monitors and disks or tapes. Most monitors incorporate a degaussing coil, which surrounds the CRT, and automatically energize this coil for a few seconds when powered up to remove color or image-distorting magnetic fields from the metal mask inside the tube. Some monitors include a button or control that can be used for additional applications of this coil to remove more stubborn magnetic traces. 2) Also the act of erasing or demagnetizing a magnetic disk or tape using a special tool called a degaussing coil.

density

The amount of data that can be packed into a certain area on a specific storage media.

desktop

A personal computer that sits on a desk.

device driver

Originally, a memory-resident program loaded by **CONFIG.SYS** that controls an unusual device, such as an expanded memory board. Windows also uses device drivers, but they are loaded through the Windows Registry or .INI files.

DHCP (Dynamic Host Configuration Protocol)

A protocol for assigning dynamic IP addresses to devices on a network. With dynamic addressing, a device can have a different IP address every time it connects to the network. Routers, gateways, and broadband modems can function as DHCP hosts to provide IP addresses to other computers and devices on the network.

Dhrystone

A benchmark program used as a standard figure of merit indicating aspects of a computer system's performance in areas other than floating-point math performance. Because the program does not use any floating-point operations, performs no I/O, and makes no operating system calls, it is most useful for measuring the processor performance of a system. The original Dhrystone program was developed in 1984 and was written in Ada, although the C and Pascal versions became more popular by 1989.

DHTML (Dynamic HTML)

A collective term for cascading style sheets, layering, dynamic fonts, and other features encompassed in standard HTML 4.0, Netscape Navigator 4.x and above, and Internet Explorer 4.x and above. Because of differences in how browsers interpret particular DHTML features, many developers incorporate browser-checking code into their web pages to enable or disable certain features depending on the browser being used to view the page.

diagnostics

Programs used to check the operation of a computer system. These programs enable the operator to check the entire system for any problems and indicate in which area the problems lie.

dialup adapter

In Windows, a software program that uses a modem to emulate a network interface card for networking. Most commonly used to connect to an Internet service provider or a dialup server for remote access to a LAN.

die

An individual chip (processor, RAM, or other integrated circuit) cut from a finished silicon chip wafer and built into the physical package that connects it to the rest of the PC or a circuit board.

differential

An electrical signaling method in which a pair of lines are used for each signal in "push-pull" fashion. In most cases, differential signals are balanced so that the same current flows on each line in opposite directions. This is unlike single-ended signals, which use only one line per signal referenced to a single ground. Differential signals have a large tolerance for common-mode noise and little crosstalk when used with twisted-pair wires even in long cables. Differential signaling is expensive because two pins are required for each signal.

digital camera

A type of camera that uses a sensor and internal or removable flash memory in place of film to record still images. Digital cameras' picture quality is usually rated in megapixels. See also [megapixel](#).

digital loopback

A test that checks the modem's RS-232 interface and the cable that connects the terminal or computer and the modem. The modem receives data (in the form of digital signals) from the computer or terminal and immediately returns the data to the screen for verification.

digital signals

Discrete, uniform signals. In this book, the term refers to the binary digits 0 and 1.

digital signature

An electronic identifier used to authenticate a message or the contents of a file. Windows 98 and above are designed to prefer digitally signed device drivers (drivers approved by the Windows Hardware Quality Labs) and will warn you if you try to install an unsigned device driver.

digital-to-analog converter (DAC)

A device for converting digital signals to analog signals. VGA-based displays are analog, so video cards that connect to them include a DAC to convert the signals to analog to drive the display.

digitize

To transform an analog wave to a digital signal a computer can store. Conversion to digital data and back is performed by a D/A converter (DAC), often a single-chip device. How closely a digitized sample represents an analog wave depends on the number of times the amplitude of a wave is measured and recorded (the rate of digitization), as well as the number of levels that can be specified at each instance. The number of possible signal levels is dictated by the resolution in bits.

DIMM (dual inline memory module)

A series of memory modules used in Pentium and newer PCs. They are available in many different versions, including those with SDRAM, DDR or DDR2, 3.3V, 2.5V or 1.8V, buffered, unbuffered or registered, and in 64-bit (non-ECC/parity) or 72-bit (ECC/parity) form. See also [DDR](#), [DDR2](#), and [SDRAM](#).

DIP (dual inline package)

A family of rectangular, integrated-circuit flat packages that have leads on the two longer sides. Package material is plastic or ceramic.

DIP switch

A tiny switch (or group of switches) on a circuit board. Named for the form factor of the carrier device in which the switch is housed.

Direct Media Interface (DMI)

2GBps high-speed bus used by Intel in its E7xxx server and 9xx desktop chipsets. Also known as Integrated Hub Architecture (IHA) 2.0.

direct memory access (DMA)

A process by which data moves between a disk drive (or other device) and system memory without direct control of the central processing unit, thus freeing it up for other tasks.

Direct Rambus DRAM

See [RDRAM](#).

directory

An area of a disk that stores the titles given to the files saved on the disk and serves as a table of contents for those files. Contains data that identifies the name of a file, the size, the attributes (system, hidden, read-only, and so on), the date and time of creation, and a pointer to the location of the file. Each entry in a directory is 32 bytes long. Windows refers to subdirectories (directories beneath the root directory) as folders.

DirectX

A set of graphics-related drivers and APIs that translates generic hardware commands into specific commands for particular pieces of hardware. Developed by Microsoft, DirectX lets graphical or multimedia applications take advantage of specific features supported by various graphics accelerators.

disc

Flat, circular, rotating medium that can store various types of information, both analog and digital. *Disc* is often used in reference to optical storage media, whereas *disk* refers to magnetic storage media. *Disc* also is often used as a short form for videodisc or compact audio disc (CD).

disk

Alternative spelling for disc that generally refers to magnetic storage medium on which information can be accessed at random. Floppy disks and hard disks are examples.

disk access time

See [access time](#).

disk cache

A portion of memory on the PC motherboard or on a drive interface card or controller used to store frequently accessed information from the drive (such as the file allocation table [FAT] or directory structure) to speed up disk access. With a larger disk cache, additional data from the data portion of a drive can be cached as well. See also [cache](#), [L1 cache](#), and [L2 cache](#).

disk partition

See [partition](#).

display

A device used for viewing information generated by a computer.

display adapter

The interface between the computer and the monitor that transmits the signals which appear as

images on the display. This can take the form of an expansion card or a chip built into the motherboard.

dithering

The process of creating more colors and shades from a given color palette. In monochrome displays or printers, dithering varies the black-and-white dot patterns to simulate shades of gray. Grayscale dithering is used to produce different shades of gray when the device can produce only limited levels of black or white outputs. Color screens or printers use dithering to create additional colors by mixing and varying the dot sizing and spacing. For example, when converting from 24-bit color to 8-bit color (an 8-bit palette has only 256 colors compared to the 24-bit palette's millions), dithering adds pixels of different colors to simulate the original color. Error diffusion is a type of dithering best suited for photographs.

DLC (Data Link Control)

Refers to the Data Link Layer in the OSI model. Every network interface card (NIC) has a unique DLC address or DLC identifier (DLCI) that identifies the node on the network. For Ethernet networks, the DLC address is usually called the Media Access Control (MAC) address.

DLL (Dynamic Link Library)

An executable driver program module for Microsoft Windows that can be loaded on demand, linked in at runtime, and subsequently unloaded when the driver is no longer needed.

DLT (digital linear tape)

A tape drive technology that writes data in multiple linear tracks as tape is wound forward and backward. Supports native/2:1 compressed capacities of up to 80/160GB. See also [Super DLT \(SDLT\)](#).

DMA

See [direct memory access](#).

DMI (Desktop Management Interface)

DMI is an operating-system and protocol-independent standard developed by the Desktop Management Task Force (DMTF) for managing desktop systems and servers. DMI provides a bidirectional path to interrogate all the hardware and software components within a PC, enabling hardware and software configurations to be monitored from a central station in a network.

DNS (domain name system or service)

An Internet service that translates domain names into numeric IP addresses. Every time you use a domain name, a DNS server must translate the name into the corresponding IP address.

docking station

Equipment that enables a laptop or notebook computer to use peripherals and accessories normally associated with desktop systems.

DOCSIS

See [*CableLabs Certified Cable Modem*](#).

doping

Adding chemical impurities to silicon (which is naturally a nonconductor) to create a material with semiconductor properties that is then used in the manufacturing of electronic chips.

DoS (denial of service)

An Internet attack on a resource that prevents users from accessing email, websites, or other services. It usually exploits security shortcomings in email or web servers. See also [*DDoS*](#).

DOS (Disk Operating System)

A collection of programs stored on the DOS disk that contain routines enabling the system and user to manage information and the hardware resources of the computer. DOS must be loaded into the computer before other programs can be started.

dot pitch

A measurement of the width of the dots that make up a pixel. The smaller the dot pitch, the sharper the image.

dot-matrix printer

An impact printer that prints characters composed of dots. Characters are printed one at a time by pressing the ends of selected wires against an inked ribbon and paper.

double-conversion online UPS

An advanced UPS design that converts AC power to DC for UPS battery charging and back to AC. This type of UPS provides excellent power conditioning and supports long run times and multiple servers with a single unit.

double density (DD)

An indication of the storage capacity of a floppy drive or disk in which eight or nine sectors per track are recorded using MFM encoding. See also [*MFM encoding*](#).

download

The process of receiving files from another computer.

downtime

Operating time lost because of a computer malfunction.

DPMI (DOS Protected Mode Interface)

An industry-standard interface that allows DOS applications to execute program code in the protected mode of the 286 or later Intel processor. The DPMI specification is available from Intel.

DPMS (Display Power Management Signaling)

A VESA standard for signaling a monitor or display to switch into energy conservation mode. DPMS provides for two low-energy modes: standby and suspend.

DRAM (dynamic random access memory)

The most common type of computer memory, DRAM can be manufactured very inexpensively compared to other types of memory. DRAM chips are small and inexpensive because they normally require only one transistor and a capacitor to represent each bit. The capacitors must be energized every 15ms or so (hundreds of times per second) to maintain their charges. DRAM is volatile, meaning it loses data with no power or without regular refresh cycles.

drive

A mechanical device that manipulates data storage media.

driver

A program designed to interface a particular piece of hardware to an operating system or other standard software.

drum

The cylindrical photoreceptor in a laser printer that receives the document image from the laser and applies it to the page as it slowly rotates.

DSL (digital subscriber line)

A high-speed digital modem technology. DSL is either symmetric or asymmetric. Asymmetric provides faster downstream speeds, which is suited for Internet usage and video on demand. Symmetric provides the same rate coming and going. See also [*ADSL*](#).

DSM (digital storage media)

A digital storage or transmission device or system.

DSP (digital signal processor)

Dedicated, limited-function processor often found in modems, sound cards, cellular phones, and so on.

DTE (data terminal [or terminating] equipment)

The device, usually a computer or terminal, that generates or is the final destination of data. See also [DCE](#).

dual cavity pin grid array

Chip packaging designed by Intel for use with the Pentium Pro processor that houses the processor die in one cavity of the package and the L2 cache memory in a second cavity within the same package.

dual-core processor

A processor that contains two distinct physical processor cores in a single package. This type of processor provides most of the benefits of dual processor designs at a lower cost.

dual independent bus (DIB) architecture

A processor technology with the existence of two independent buses on the processorthe L2 cache bus and the processor-to-main memory system bus. The processor can use both buses simultaneously, thus getting as much as two times more data into and out of the processor than a single bus architecture processor. The Intel Pentium Pro, Pentium II, and newer processors from Intel and AMD (such as the AMD Athlon and Duron) have DIB architecture.

dual scan display

A lower-quality but economical type of LCD color display that has an array of transistors running down the x and y axes of two sides of the screen. The number of transistors determines the screen's resolution.

dumb terminal

A screen and keyboard device with no inherent processing power connected to a computer that is usually remotely located.

duplex

Indicates a communications channel capable of carrying signals in both directions.

Duron

A low-cost version of the Athlon processor with less L2 cache. Available in the Socket A (462-pin) chip package.

DVD (digital versatile disc)

Originally called digital video disc. A new type of high-capacity CD-ROM disc and drive format with up to 28 times the capacity of a standard CD-ROM. The disc is the same diameter as a CD-ROM but can be recorded on both sides and on two layers for each side. Each side holds 4.7GB on a single layer disc, whereas dual-layer versions hold 8.5GB per side, for a maximum of 17GB total if both sides and both layers are used, which is the equivalent of 28 CD-ROMs. DVD drives can read standard audio CDs and CD-ROMs.

DVD burner

Popular term for a rewritable DVD drive, particularly one that uses DVD-R/RW or DVD+R/RW media.

DVD-A

A DVD format designed to support high-quality music and audio. DVD-A uses 24-bit sampling at 96KHz, significantly better than CD audio (16-bit at 44.1KHz). Unlike DVD, DVD-A discs can be played on conventional CD players but produce the highest quality only when played on DVD-A players.

DVD-R

A writeable DVD format compatible with standalone DVD players and DVD-ROM drives. DVD-R was introduced by Pioneer and was released to the DVD Forum (www.dvdforum.org) in July 1997. It uses a wobbled-groove recording process to store 4.7GB of data and is optimized for sequential data access. See also [DVD-RW](#).

DVD-R DL

A dual-layer DVD format based on DVD-R that supports up to 8.5GB of data. See also [DVD-R](#).

DVD+R

A writeable DVD format compatible with standalone DVD players and DVD-ROM drives. DVD+R was developed by the DVD+RW Alliance (www.dvdrw.com), whose members include Microsoft, Sony, HP, and Dell. In addition, it is supported by second-generation DVD+RW drives and holds 4.7GB of data. DVD+R/RW are the only recordable DVD formats that fully support the Mt. Rainier (also called EasyWrite) standard coming in Windows Longhorn (in 2005). This enables discs to be used right out of the box with automatic background formatting and no additional packet-writing software required. DVD+R/RW are the most compatible, fastest, most capable, and most popular of all the

recordable DVD formats. See also [DVD+RW](#).

DVD+R DL

A dual-layer DVD format based on DVD+R that supports up to 8.5GB of data. See also [DVD+R](#).

DVD-RAM

A rewritable DVD format developed by Panasonic, Toshiba, and Hitachi and supported by the DVD Forum. DVD-RAM is the oldest DVD rewritable format, but because the media uses a caddy and has a lower reflectivity than normal DVD media, DVD-RAM discs are not compatible with other types of DVD drives or with standalone DVD players. Older DVD-RAM drives use media in caddies, but newer drives do not use caddies.

DVD-RW

A rewritable DVD format developed by Pioneer and released to the DVD Forum in November 1999. It uses a phase-change technology similar to CD-RW. As with most CD-RW media and drives, the entire disc must be formatted before it can be used. Its write speed is also lower than DVD+RW, and the entire disc must be erased before it can be used to store new data. See also [DVD-R](#).

DVD+RW

A rewritable DVD format developed by the DVD+RW Alliance; the first DVD+RW drives were released in 2001. DVD+RW uses a phase-change technology similar to CD-RW and DVD-RW. DVD+R/RW are the only recordable DVD formats that fully support the Mt. Rainier (EasyWrite) standard coming in Windows Longhorn (in 2005). This enables discs to be used right out of the box with automatic background formatting and no additional packet-writing software required. DVD+R/RW are the most compatible, fastest, most capable, and most popular of all the recordable DVD formats. See also [DVD+R](#).

DVD±RW

A DVD drive capable of reading and writing to both DVD+R/RW and DVD-R/RW media. Some of these drives also support some or all of these media types: DVD+R DL, DVD-R DL, and DVD-RAM.

DVI (Digital Video Interactive)

A standard that was originally developed at RCA Laboratories and sold to Intel in 1988. DVI integrates digital motion, still video, sound, graphics, and special effects in a compressed format. DVI is a highly sophisticated hardware compression technique used in interactive multimedia applications.

DVI (Digital Visual Interface)

The current de facto standard for LCD displays developed by the Digital Display Working Group in April 1999. DVI-D provides digital signals only, whereas DVI-I (which is more common) provides both digital and analog signals. A DVI-I connector can be converted to VGA with an external adapter.

Dvorak keyboard

A keyboard design by August Dvorak that was patented in 1936 and approved by ANSI in 1982. Provides increased speed and comfort and reduces the rate of errors by placing the most frequently used letters in the center for use by the strongest fingers. Finger motions and awkward strokes are reduced by more than 90% in comparison with the familiar QWERTY keyboard. The Dvorak keyboard has the five vowel keys, AOEUI, together under the left hand in the center row and the five most frequently used consonants, DHTNS, under the fingers of the right hand.

dynamic execution

A processing technique that enables the processor to dynamically predict the order of instructions and execute them out of order internally if necessary for an improvement in speed. Uses these three techniques: Multiple Branch Prediction, Data Flow Analysis, and Speculative Execution.

E2000

Also called Energy 2000, this is a Swiss-developed standard for power management that calls for computer monitors to use only 5 watts of power when in standby mode.

EBCDIC (Extended Binary Coded Decimal Interchange Code)

An IBM-developed, 8-bit code for the representation of characters. It allows 256 possible character combinations within a single byte. EBCDIC is the standard code on IBM minicomputers and mainframes, but not on the IBM microcomputers, where ASCII is used instead.

ECC (error correcting code)

A type of system memory or cache that is capable of detecting and correcting some types of memory errors without interrupting processing.

ECP (enhanced capabilities port)

A type of high-speed parallel port jointly developed by Microsoft and Hewlett-Packard that offers improved performance for the parallel port and requires special hardware logic. ECP ports use both an IRQ and a DMA channel. See also [IEEE 1284](#).

edge connector

The part of a circuit board containing a series of printed contacts that is inserted into an expansion slot or a connector.

EDO (extended data out) RAM

A type of RAM chip that enables a timing overlap between successive accesses, thus improving memory cycle time.

EEB

Entry-Level Electronics Bay is a specification for pedestal servers developed by SSI. See also [SSI](#).

EEPROM (electrically erasable programmable read-only memory)

A type of nonvolatile memory chip used to store semipermanent information in a computer, such as the BIOS. An EEPROM can be erased and reprogrammed directly in the host system without special equipment. This is used so manufacturers can upgrade the ROM code in a system by supplying a special program that erases and reprograms the EEPROM chip with the new code. Also called flash ROM.

EGA (enhanced graphics adapter)

A type of PC video display adapter first introduced by IBM on September 10, 1984, that supports text and graphics. Text is supported at a maximum resolution of 80x25 characters in 16 colors with a character box of 8x14 pixels. Graphics are supported at a maximum resolution of 640x350 pixels in 16 (from a palette of 64) colors. The EGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz, 18.432KHz, or 21.85KHz, and it supports TTL color or TTL monochrome displays.

EIA (Electronic Industries Association)

An organization that defines electronic standards in the United States.

EIDE (Enhanced Integrated Drive Electronics)

A specific Western Digital implementation of the ATA-2 specification. See also [ATA-2](#).

eight-way server

A server containing eight processors.

EISA (Extended Industry Standard Architecture)

An extension of the Industry Standard Architecture (ISA) bus developed by IBM for the AT. The EISA design was led by Compaq Corporation. Later, eight other manufacturers (AST, Epson, Hewlett-Packard, NEC, Olivetti, Tandy, Wyse, and Zenith) joined Compaq in a consortium founded September 13, 1988. This group became known as the "gang of nine." The EISA design was patterned largely after IBM's Micro Channel Architecture (MCA) in the PS/2 systems, but unlike MCA, EISA enables backward compatibility with older plug-in adapters. EISA products became obsolete after the development of the PCI slot architecture. See also [PCI](#).

electronic mail (email)

A method of transferring messages from one computer to another.

electrostatic discharge (ESD)

The grounding of static electricity. A sudden flow of electricity between two objects at different electrical potentials. ESD is a primary cause of integrated circuit damage or failure.

ELF (extremely low frequency)

A very low-frequency electromagnetic radiation generated by common electrical appliances, including computer monitors. The Swedish MPR II standard governs this and other emissions. Also called VLF (very low frequency).

EM64T

Intel's implementation of the AMD64 64-bit processor architecture. See also [AMD64](#).

embedded controller

In disk drives, a controller built into the same physical unit that houses the drive rather than on a separate adapter card. IDE and SCSI drives both use embedded controllers.

embedded servo data

Magnetic markings embedded between or inside tracks on disk drives that use voice-coil actuators. These markings enable the actuator to fine-tune the position of the read/write heads.

EMM (expanded memory manager)

A driver that provides a software interface to expanded memory. EMMs were originally created for expanded memory boards but also can use the memory management capabilities of the 386 or later processors to emulate an expanded memory board. EMM386.EXE is an example of an EMM that comes with DOS and Windows 9x.

EMS (Expanded Memory Specification)

Sometimes also called the LIM spec because it was developed by Lotus, Intel, and Microsoft. Provides a way for microcomputers running under DOS to access additional memory. EMS memory management provides access to a maximum of 32MB of expanded memory through a small (usually 64KB) window in conventional memory. EMS is a cumbersome access scheme designed primarily for pre-286 systems that could not access extended memory.

emulator

A piece of test apparatus that emulates or imitates the function of a particular chip.

encoding

The protocol by which data is carried or stored by a medium.

encryption

The translation of data into unreadable codes to maintain security.

endec (encoder/decoder)

A device that takes data and clock signals and combines or encodes them using a particular encoding scheme into a single signal for transmission or storage. The same device also later separates or decodes the data and clock signals during a receive or read operation. Sometimes called a data separator.

Energy Star

A certification program started by the Environmental Protection Agency. Energy Starcertified computers and peripherals are designed to draw less than 30 watts of electrical energy from a standard 110-volt AC outlet during periods of inactivity. Also called Green PCs. See also [E2000](#).

Enhanced CD (CD-E)

See [Blue Book](#).

enhanced graphics adapter

See [EGA](#).

enhanced small device interface

See [ESDI](#).

e-PCI-X

The PICMG 1.2 embedded PCI-X specification for passive backplane computers. See also [PICMG](#).

EPIC

Short for Explicitly Parallel Instruction Computing; the RISC-based 64-bit processor architecture used by the Intel Itanium and Itanium 2 processors. EPIC is not the same architecture as AMD64 or EM64T. See also [RISC](#).

EPP (enhanced parallel port)

A type of parallel port developed by Intel, Xircom, and Zenith Data Systems that operates at almost

ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals, such as LAN adapters, disk drives, and tape backups. See also [IEEE 1284](#).

EPROM (erasable programmable read-only memory)

A type of read-only memory (ROM) in which the data pattern can be erased to allow a new pattern. EPROM usually is erased by ultraviolet light and recorded by a higher-than-normal voltage programming signal.

equalization

A compensation circuit designed into modems to counteract certain distortions introduced by the telephone channel. Two types are used: fixed (compromise) equalizers and those that adapt to channel conditions (adaptive). Good-quality modems use adaptive equalization.

error control

Various techniques that check the reliability of characters (parity) or blocks of data. V.42, MNP, and HST error-control protocols use error detection (CRC) and retransmission of error frames (ARQ).

error message

A word or combination of words to indicate to the user that an error has occurred somewhere in the program.

ESCD (extended system configuration data)

Area in CMOS or Flash/NVRAM where plug-and-play information is stored.

ESDI (Enhanced Small Device Interface)

A hardware standard developed by Maxtor and standardized by a consortium of 22 disk drive manufacturers on January 26, 1983. A group of 27 manufacturers formed the ESDI steering committee on September 15, 1986, to enhance and improve the specification. A high-performance interface used primarily with hard disks, ESDI enables a maximum data transfer rate to and from a hard disk of between 10Mbps and 24Mbps. ESDI was replaced by IDE and SCSI interfaces. ESDI drives use the same 34-pin and 20-pin cables used by ST412/ST506 drives.

Ethernet

A type of network protocol developed in the late 1970s by Bob Metcalf at Xerox Corporation and endorsed by the IEEE. One of the oldest LAN communications protocols in the personal computing industry, Ethernet networks use a collision-detection protocol to manage contention. Ethernet is defined by the IEEE 802.3 standard. See also [10BASE-T](#).

expanded memory

Otherwise known as EMS memory, this is memory that conforms to the EMS specification. Requires a special device driver and conforms to a standard developed by Lotus, Intel, and Microsoft.

expansion card

An integrated circuit card that plugs into an expansion slot on a motherboard to provide access to additional peripherals or features not built in to the motherboard. Also called an add-in board.

expansion slot

A slot on the motherboard that physically and electrically connects an expansion card to the motherboard and the system buses.

extended graphics array

See [XGA](#).

extended memory

Direct processor-addressable memory addressed by an Intel (or compatible) 286 or more advanced processor in the region beyond the first megabyte. Addressable only in the processor's protected mode of operation.

extended partition

A nonbootable DOS partition (also supported by Windows) containing DOS volumes. Starting with DOS v3.3, the FDISK program can create two partitions that serve DOS: an ordinary, bootable partition (called the primary partition) and an extended partition, which can contain as many as 23 volumes from D: to Z:.

external device

A peripheral installed outside the system case.

extra-high density (ED)

An indication of the storage capacity of a floppy drive or disk in which 36 sectors per track are recorded using a vertical recording technique with MFM encoding.

FAQ (frequently asked questions)

Name for a list of popular questions and answers covering any particular subject.

Fast Ethernet

Popular term for 100BASE-T and other 100Mbps versions of Ethernet. Fast Ethernet uses CAT 5 cable.

Fast Page Mode RAM

A type of RAM that improves on standard DRAM speed by enabling faster access to all the data within a given row of memory by keeping the row address the same and changing only the column.

Fast-ATA (fast AT attachment interface)

Also called Fast ATA-2, these are specific Seagate and Quantum implementations of the ATA-2 interface. See also [ATA-2](#).

FAT (file allocation table)

A table held near the outer edge of a disk that tells which sectors are allocated to each file and in what order.

FAT32

A disk file allocation system from Microsoft that uses 32-bit values for FAT entries instead of the 16-bit values used by the original FAT system, enabling partition sizes up to 2TB (terabytes). Although the entries are 32-bits, 4-bits are reserved and only 28-bits are used. FAT32 first appeared in Windows 95B and is also supported by Windows 98, Windows Me, Windows 2000, and Windows XP.

fault tolerance

The capability of a computer to withstand a failure. Many levels of fault tolerance exist, and fault tolerance can be applied to several components or systems in the computer. For example, ECC (error correcting code) memory is considered fault tolerant because it is typically capable of automatically identifying and correcting single bit errors.

fax/modem

A peripheral that integrates the capabilities of a fax machine and a modem in one expansion card or external unit. Almost all 14.4Kbps and faster modems sold for use in desktop or portable PCs include fax capabilities.

FCC Part 15

The section of the FCC regulations governing emissions from electronics devices. FCC Part 15 Class A devices are suitable for business but not residential use because they emit more interference than FCC Part 15 Class B devices (which are safe in residential areas). Most server components are FCC Part 15 Class A devices.

FC-PGA (flip-chip pin grid array)

A type of chip packaging first used in the Socket PGA370 version of the Pentium III where the raw processor die has bumped contacts spaced on the face of the die and is mounted facedown to a pin grid array carrier. The heatsink is then directly attached to the back of the raw silicon die surface.

FDISK

The name of the disk-partitioning program under several operating systems, including DOS and Windows 9x/Me, to create the master boot record and allocate partitions for the operating system's use.

feature connector

On a video adapter, a connector that enables an additional video feature card, such as a separate 3D accelerator, video capture card, or MPEG decoder, to be connected to the main video adapter and display.

ferro-resonant UPS

A type of UPS design noted for excellent power conditioning, but also for its bulk and inefficient use of power. It has been largely replaced by double-conversion online UPS units. See also [*double-conversion online UPS*](#).

fiber optic

A type of cable or connection using strands or threads of glass to guide a beam of modulated light. Allows for very high-speed signaling and multiplexing as well as the combining of many data streams along a single cable.

FIFO (first-in, first-out)

A method of storing and retrieving items from a list, table, or stack so that the first element stored is the first one retrieved.

file

A collection of information kept somewhere other than in random-access memory.

file attribute

Information held in the attribute byte of a file's directory entry.

file compression

See [*compressed file*](#).

filename

The name given to the disk file. For DOS, it must be from one to eight characters long and can be followed by a filename extension, which can be from one to three characters long. Windows 9x and above ease these constraints by allowing filenames of up to 255 characters including the directory path.

firewall

A hardware or software system designed to prevent unauthorized access to or from a private network.

FireWire

Also called IEEE 1394 or i.Link. A serial I/O interface standard that is extremely fast, with data transfer rates up to 400MBps, 800MBps, or 3.2GBps, depending on the version of standard used. Most current implementations use the 400MBps IEEE 1394a version.

firmware

Software contained in a read-only memory (ROM) device. A cross between hardware and software, firmware can be easily updated if stored in an EEPROM or flash ROM chip. See also [EEPROM](#) and [flash ROM](#).

fixed disk

Also called a hard disk, it's a disk that can't be removed from its controlling hardware or housing. Made of rigid material with a magnetic coating and used for the mass storage and retrieval of data.

flash ROM

A type of EEPROM developed by Intel that can be erased and reprogrammed in the host system. See also [EEPROM](#).

flicker

A monitor condition caused by refresh rates that are too low, in which the display flashes visibly. This can cause eyestrain or more severe physical problems.

floating-point unit (FPU)

Sometimes called the math coprocessor; handles the more complex calculations of the processing cycle.

floppy disk

A removable disk using flexible magnetic media enclosed in a semirigid or rigid plastic case.

floppy disk controller

The logic and interface that connects a floppy disk drive to the system.

floppy tape

A tape standard that uses drives connecting to an ordinary floppy disk controller, such as QIC-80 or Travan-1.

floptical drive

A special type of high-capacity removable disk drive that uses an optical mechanism to properly position the drive read/write heads over the data tracks on the disk. This enables more precise control of the read/write positioning and therefore narrower track spacing and more data packed into a smaller area than traditional floppy disks. The LS-120 and LS-240 SuperDisk drives are recent examples of floptical drives.

flow control

A mechanism that compensates for differences in the flow of data input to and output from a modem or other device.

FM encoding

Frequency modulation encoding. An outdated method of encoding data on the disk surface that uses up half the disk space with timing signals.

FM synthesis

An audio technology that uses one sine wave operator to modify another and create an artificial sound that mimics an instrument.

folder

In a graphical user interface, a simulated file folder that holds documents (text, data, or graphics), applications, and other folders. A folder is similar to a DOS subdirectory.

footprint

Describes the shape of something. See also [*form factor*](#).

form factor

The physical dimensions of a device. Two devices with the same form factor are physically interchangeable. The IBM PC, XT, and XT Model 286, for example, all use power supplies that are

internally different but have exactly the same form factor.

FORMAT

The DOS/Windows format program that performs both low- and high-level formatting on floppy disks but only high-level formatting on hard disks.

formatted capacity

The total number of bytes of data that can fit on a formatted disk. The unformatted capacity is higher because space is lost defining the boundaries between sectors.

formatting

Preparing a disk so the computer can read or write to it. Checks the disk for defects and constructs an organizational system to manage information on the disk.

FORTRAN (formula translator)

A high-level programming language developed in 1954 by John Backus at IBM primarily for programs dealing with mathematical formulas and expressions similar to algebra and used primarily in scientific and technical applications.

four-way server

A server containing four processors.

fragmentation

The state of having a file scattered around a disk in pieces rather than existing in one contiguous area of the disk. Fragmented files are slower to read than files stored in contiguous areas and can be more difficult to recover if the FAT or a directory becomes damaged.

frame

1) A data communications term for a block of data with header and trailer information attached. The added information usually includes a frame number, block size data, error-check codes, and start/end indicators. 2) A single, complete picture in a video or film recording. A video frame consists of two interlaced fields of either 525 lines (NTSC) or 625 lines (PAL/SECAM), running at 30 frames per second (NTSC) or 25 frames per second (PAL/SECAM).

frame buffer

A memory device that stores, pixel by pixel, the contents of an image. Frame buffers are used to refresh a raster image. Sometimes they incorporate local processing capability. The "depth" of the frame buffer is the number of bits per pixel, which determines the number of colors or intensities that can be displayed.

frame rate

The speed at which video frames are scanned or displayed: 30 frames per second for NTSC and 25 frames per second for PAL/SECAM.

FTP (File Transfer Protocol)

A method of transferring files over the Internet. FTP can be used to transfer files between two machines on which the user has accounts. Anonymous FTP can be used to retrieve a file from a server without having an account on that server.

full duplex

Signal flow in both directions at the same time. In microcomputer communications, it also can refer to the suppression of the online local echo. 100BASE-TX network cards capable of full-duplex operations can run at an effective speed of 200Mbps when full-duplex operation is enabled.

full-height drive

A drive unit that is 3 1/4" high, 5 1/4" wide, and 8" deep. Equal to two half-height drive bays.

full-motion video

A video sequence displayed at full television standard resolutions and frame rates. In the U.S., this equates to NTSC video at 30 frames per second.

function keys

Special-purpose keys that can be programmed to perform various operations. They serve many functions, depending on the program being used.

G.lite

A popular form of ADSL, G.lite can be self-installed by the user. Also referred to as the G.992.2 standard.

gas-plasma display

Commonly used in portable systems, it's a type of display that operates by exciting a gas usually neon or an argon-neon mixture through the application of a voltage. When sufficient voltage is applied at the intersection of two electrodes, the gas glows an orange-red. Because gas-plasma displays generate light, they require no backlighting.

gateway

Officially, an application-to-application conversion program or system. For example, an email gateway converts from SMTP (Internet) email format to MHS (Novell) email format. The term gateway is also used as a slang term for router. See also [router](#).

gender

When describing connectors for PCs, connectors are described as male if they have pins or female if they have receptacles designed to accept the pins of a male connector.

genlocking

The process of aligning the data rate of a video image with that of a digital device to digitize the image and enter it into computer memory. The machine that performs this function is known as a genlock.

Ghost

Popular utility program sold by Symantec that can be used to create a compressed version of a drive's contents and clone it to one or more PCs over a network or via CD storage.

gibi

A multiplier equal to 1,073,741,824.

gibibyte (Gi)

A unit of information storage equal to 1,073,741,824 bytes (1,024x1,024x1,024 equals a Gi). Formerly known as a binary gigabyte. See also [gigabyte](#) and [kilobyte](#).

GIF (Graphics Interchange Format)

A popular raster graphics file format developed by CompuServe that handles 8-bit color (256 colors) and uses the LZW method to achieve compression ratios of approximately 1.5:1 to 2:1. You can reduce the size of a GIF file even more by dropping unused colors from the file.

giga

A multiplier indicating one billion (1,000,000,000) of some unit. Abbreviated as g or G. The binary giga (1,073,741,824) is now referred to as a gibi. See also [gibi](#).

gigabyte (GB)

A unit of information storage equal to 1,000,000,000 bytes. The value formerly called a binary GB (1,073,741,824 bytes) is now called a gibibyte. See also [gibibyte](#).

gigahertz

GHz is used to measure the clock frequency of high-performance processors. The first 1GHz desktop processor was introduced by AMD (a 1GHz Athlon) in March 2000.

GPU (graphics processing unit)

A 3D graphics chip that contains advanced 3D rendering features such as hardware, vertex, and pixel shaders. NVIDIA's GeForce 3 and GeForce 4 Ti series; the ATI Radeon 7xxx, 8xxx, and 9xxx series; and the Matrox Parhelia series are typical GPUs. See also [hardware shader](#), [pixel shader](#), and [vertex shader](#).

graphics accelerator

A video processor or chipset specially designed to speed the display and rendering of graphical objects onscreen. Originally, accelerators were optimized for 2D or 3D operations, but all current graphics accelerators, such as NVIDIA's GeForce and ATI's RADEON series, accelerate both types of data.

graphics adapter

See [video adapter](#).

Green Book

The standard for Compact Disc-Interactive (CD-I). Philips developed CD-I technology for the consumer market to be connected to a television instead of a computer monitor. CD-I is not a computer system but a consumer device that made a small splash in the market and disappeared. CD-I discs require special code and are not compatible with standard CD-ROMs. A CD-ROM can't be played on the CD-I machine, but Red Book audio can be played on it.

GUI (graphical user interface)

A type of program interface that enables users to choose commands and functions by pointing to a graphical icon using either a keyboard or pointing device, such as a mouse. Windows is the most popular GUI available for PC systems.

half duplex

Signal flow in both directions but only one way at a time. In microcomputer communications, half duplex can refer to activation of the online local echo, which causes the modem to send a copy of the transmitted data to the screen of the sending computer.

half-height drive

A drive unit that is 1.625" high, 5 1/4" wide, and 8" deep.

half-toning

A process that uses dithering to simulate a continuous tone image, such as a photograph or shaded drawing, using various sizes of dots. Newspapers, magazines, and many books use halftoning. The human eye merges the dots to give the impression of gray shades.

handshaking

The process of exchanging information about speeds and protocols between analog modems to establish a dialup connection. If your modem volume is high enough, you can hear handshaking as a series of distinct tones at the start of a modem-to-modem call.

hard disk

A high-capacity disk storage unit characterized by a normally nonremovable rigid substrate medium. The platters in a hard disk usually are constructed of aluminum or glass/ceramic. Also sometimes called a fixed disk.

hard error

An error in reading or writing data caused by damaged hardware.

hard reset

Resetting a system via the hardware, usually by pressing a dedicated reset button wired to the motherboard/processor reset circuitry. Does not clear memory like a cold boot does. See also [cold boot](#).

hardware

Physical components that make up a microcomputer, monitor, printer, and so on.

hardware shader

A general term describing the processing of vertex or pixel shading in a GPU's hardware. GPUs such as the ATI 8xxx and 9xxx series or the NVIDIA GeForce 3 and GeForce 4 Ti-series GPU chips have hardware shaders compatible with DirectX 8 and above.

HDLC (High-Level Data Link Control)

A standard protocol developed by the ISO for software applications and communicating devices operating in synchronous environments. Defines operations at the link level of communications for example, the format of data frames exchanged between modems over a phone line.

head

A small electromagnetic device inside a drive that reads, records, and erases data on the media.

head actuator

The device that moves read/write heads across a disk drive's platters. Most drives use a stepper-motor or voice-coil actuator.

head crash

A (usually) rare occurrence in which a read/write head strikes a platter surface with sufficient force to damage the magnetic medium.

head parking

A procedure in which a disk drive's read/write heads are moved to an unused track so they will not damage data in the event of a head crash or other failure.

head seek

The movement of a drive's read/write heads to a particular track.

heatsink

A mass of metal attached to a chip carrier or socket for the purpose of dissipating heat. Some heatsinks are passive (relying on existing air currents only), but most heatsinks on processors are active (including a fan). Many video card accelerator chips and motherboard North Bridge chips are also fitted with heatsinks today.

helical scan

A type of recording technology that has vastly increased the capacity of tape drives. Invented for use in broadcast systems and now used in VCRs. Conventional longitudinal recording records a track of data straight across the width of a single-track tape. Helical scan recording packs more data on the tape by positioning the tape at an angle to the recording heads. The heads spin to record diagonal stripes of information on the tape. Helical scan is used by DAT/DDS, Exabyte, and AIT drives.

hexadecimal number

A number encoded in base-16, such that digits include the letters AF and the numerals 09 (for example, 8BF3, which equals 35,827 in base-10).

hidden file

A file not displayed in DOS directory listings because the file's attribute byte holds a special setting.

high density (HD)

An indication of the storage capacity of a floppy drive or disk, in which 15 or 18 sectors per track are recorded using MFM encoding.

High Sierra format

A standard format for placing files and directories on CD-ROMs, proposed by an ad hoc committee of computer vendors, software developers, and CD-ROM system integrators. (Work on the format proposal began at the High Sierra Hotel in Lake Tahoe, Nevada.) A revised version of the format was adopted by the ISO as ISO 9660. Use the ISO 9660 format to create cross-platform CD-R recordings.

high-definition television (HDTV)

Video formats offering greater visual accuracy (or resolution) than current NTSC, PAL, or SECAM broadcast standards. HDTV formats generally range in resolution from 655 to 2,125 scanning lines, having an aspect ratio of 5:3 (or 1.67:1) and a video bandwidth of 30MHz50MHz (5+ times greater than the NTSC standard). Digital HDTV has a bandwidth of 300MHz. HDTV is subjectively comparable to 35mm film.

high-level formatting

Formatting performed by the DOS FORMAT program. Among other things, it creates the root directory and FATs.

history file

A file created by utility software to keep track of earlier use of the software. Many backup programs, for example, keep history files describing earlier backup sessions.

hit ratio

In describing the efficiency of a disk or memory cache, the hit ratio is the ratio of the number of times the data is found in the cache to the total number of data requests. 1:1 is a perfect hit ratio, meaning that every data request was found in the cache. The closer to 1:1 the ratio is, the more efficient the cache.

HMA (high memory area)

The first 64KB of extended memory, which typically is controlled by the HIMEM.SYS device driver. Real-mode programs can be loaded into the HMA to conserve conventional memory. Normally, DOS 5.0 and later use the HMA exclusively to reduce the DOS conventional memory footprint.

HomePNA

A home networking standard using existing home or office telephone wiring to obtain speeds up to 11Mbps.

HomeRF

A wireless home network using radio waves to obtain speeds up to 11Mbps.

horizontal scan rate

In monitors, the speed at which the electron beam moves laterally across the screen. It's normally expressed as a frequency; typical monitors range from 31.5KHz to 90KHz, with the higher frequencies being more desirable.

host

The main device when two or more devices are connected. When two or more systems are connected, the system that contains the data is typically called the host, whereas the other is called the guest or user.

host protected area

A technique used in ATA-7 and newer ATA drive specifications for reducing the reported size of the hard disk. The space not reported is used to store system recovery data.

hotfix

A software patch for a Microsoft application or operating system. Hotfixes can be downloaded individually from the Windows Update website or as a service pack. Microsoft also calls them quick fix engineering (QFE) files.

hot-plug RAID memory

A memory technology used on servers to permit hot-swapping of defective memory modules without loss of memory contents. Memory modules form a RAID array similar in operation to a RAID 5 disk array.

HPT (high-pressure tin)

A PLCC socket that promotes high forces between socket contacts and PLCC contacts for a good connection.

HST (High-Speed Technology)

The now-obsolete U.S. Robotics proprietary high-speed modem-signaling scheme, developed as an interim protocol until the V.32 protocol could be implemented in a cost-effective manner.

HT technology

See [*hyper-threading technology*](#).

HTML (Hypertext Markup Language)

A language used to describe and format plain-text files on the Web. HTML is based on pairs of tags that enable the user to mix graphics with text, change the appearance of text, and create hypertext documents with links to other documents. See also [DHTML](#).

HTTP (Hypertext Transfer Protocol)

The protocol that describes the rules a browser and server use to communicate over the World Wide Web. HTTP allows a web browser to request HTML documents from a web server. See also [hypertext](#).

hub

A common connection point for multiple devices in a network. A hub contains a number of ports to connect several segments of a LAN together. When a packet arrives at one of the ports on the hub, it is copied to all the other ports so all the segments of the LAN can see all the packets. A hub can be passive, intelligent (allowing remote management, including traffic monitoring and port configuration), or switching. A switching hub is also called a switch. See also [switch](#).

Huffman coding

A technique that minimizes the average number of bytes required to represent the characters in a text. Huffman coding works for a given character distribution by assigning short codes to frequently occurring characters and longer codes to infrequently occurring characters.

hybrid fiber coaxial (HFC)

A network (such as that used by digital cable TV and two-way cable modems) that uses fiber-optic cabling for its backbone with coaxial cable connections to each individual computer or TV.

hyper-threading technology

A method (also called HT technology) developed by Intel for running two different instruction streams through a processor at the same time. Introduced in 2002, HT technology was first used in the Intel Xeon processor with hyper-threading technology, with speeds starting at 2.8GHz; the first HT technology-enabled desktop processor was the 3.06GHz Pentium 4.

hypertext

A technology that enables quick and easy navigation between and within large documents. Hypertext links are pointers to other sections within the same document; other documents; or other resources, such as FTP sites, images, or sounds.

HyperTransport

AMD's high-speed technology for connecting the North Bridge and South Bridge or equivalent chips

on a motherboard. HyperTransport runs at six times the speed of the PCI bus (800MBps versus 133MBps for PCI). The original name was Lightning Data Transport (LDT). Several chipset makers, including AMD and NVIDIA, use HyperTransport.

Hz

An abbreviation for hertza frequency measurement unit used internationally to indicate one cycle per second.

i.Link

Sony's term for IEEE 1394/FireWire port. See also [FireWire](#).

I/O (input/output)

A circuit path that enables independent communication between the processor and external devices.

I/O controller hub

See [ICH](#).

I/O port (input/output port)

Used to communicate to and from another device, such as a printer or disk.

IA-64

Intel's 64-bit processor architecture, first used in the Itanium processor for servers.

IBMBIO.COM

One of the DOS system files required to boot the machine in older versions of PC-DOS (IBM's version of MS-DOS). The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

IBMDOS.COM

One of the DOS system files required to boot the machine in older versions of PC-DOS (IBM's version of MS-DOS). Contains the primary DOS routines. Loaded by **IBMBIO.COM**, it in turn loads **COMMAND.COM**.

IC (integrated circuit)

A complete electronic circuit contained on a single chip. It can consist of only a few or thousands of transistors, capacitors, diodes, or resistors, and it generally is classified according to the complexity of the circuitry and the approximate number of circuits on the chip. SSI (small-scale integration)

equals 210 circuits; MSI (medium-scale integration) equals 10100 circuits. LSI (large-scale integration) equals 1001,000 circuits, and VLSI (very-large-scale integration) equals 1,00010,000 circuits. Finally, ULSI (ultra-large-scale integration) equals more than 10,000 circuits.

ICH (I/O controller hub)

Intel's term for the chip used in its 8xx chipsets to interface with lower-speed devices such as PCI slots, USB ports, ATA drives, and other devices traditionally controlled by the South Bridge chip. ICH chips connect with the memory controller hub (the 8xx chipsets' replacement for the North Bridge) through a high-speed hub interface. Current ICH chips used by Intel 8xxseries chipsets include the ICH2 and ICH4. See also [MCH](#).

IDE (Integrated Drive Electronics)

A hard disk with the disk controller circuitry integrated within it. The first IDE drives were called hard cards. Also refers to the ATA interface standardthe standard for attaching hard disk drives to ISA bus IBM-compatible computers. IDE drives typically operate as though they are standard ST-506/412 drives. See also [ATA](#).

IEEE 802.3

See [10BASE-2](#).

IEEE 802.11 family

A family of wireless network standards commonly known as wireless Ethernet, the most popular of which include 802.11a (54Mbps using 5GHz signaling), 802.11b (11Mbps using 2.4GHz signaling), and 802.11g (54Mbps using 2.4GHz signaling). See also [Wi-Fi](#).

IEEE 1284

A series of standards for parallel ports. IEEE 1284 includes EPP and ECP configurations as well as the older bidirectional and 4-bit compatible parallel port modes. Printer cables that can work with all modes are referred to as IEEE 1284compliant cables. See also [EPP](#) and [ECP](#).

IEEE 1394

See [FireWire](#).

illegal operation

A command sent to Windows or the processor that can't be performed. Illegal operations can be triggered by software bugs or conflicts between programs in memory; although the name is reminiscent of a penalty in football, an illegal operation is hardly ever caused by the computer user. In most cases, you can continue to work and might even be able to restart the program without rebooting.

impedance

The total opposition a circuit offers to the flow of alternating current, measured in ohms.

incremental backup

A backup of all the files that have changed since the last backup.

inductive

A property in which energy can be transferred from one device to another via the magnetic field generated by the device, even though no direct electrical connection is established between the two.

.INF file

A Windows driver and device information file used to install new drivers or services.

ingot

See [boule](#).

initiator

A device attached to the SCSI bus that sends a command to another device (the target) on the SCSI bus. The SCSI host adapter plugged into the system bus is an example of a SCSI initiator.

inkjet printer

A type of printer that sprays one or more colors of ink on the paper; it can produce output with quality approaching that of a laser printer at a lower cost.

input

Data sent to the computer from the keyboard, the telephone, a video camera, another computer, paddles, joysticks, and so on.

InstallShield

A popular program used to create installation and uninstallation routines for Windows-based programs.

instruction

Program step that tells the computer what to do for a single operation.

integrated circuit

See [IC](#).

interface

A communications device or protocol that enables one device to communicate with another. Matches the output of one device to the input of the other device.

interlacing

A method of scanning alternate lines of pixels on a display screen. The odd lines are scanned first from top to bottom and left to right. The electron gun goes back to the top and makes a second pass, scanning the even lines. Interlacing requires two scan passes to construct a single image. Because of this additional scanning, interlaced screens often seem to flicker unless a long-persistence phosphor is used in the display. Interlaced monitors were used with the IBM 8514/A display card but are now obsolete for desktop computers.

interleave ratio

The number of sectors that pass beneath the read/write heads before the "next" numbered sector arrives. When the interleave ratio is 3:1, for example, a sector is read, two pass by, and then the next is read. A proper interleave ratio, laid down during low-level formatting, enables the disk to transfer information without excessive revolutions due to missed sectors. All modern IDE and SCSI drives have a 1:1 interleave ratio.

interleaved memory

The process of alternating access between two banks of memory to overlap accesses, thus speeding up data retrieval. Systems that require only one memory module per bank to operate can work more quickly when two are installed if the system supports interleaved memory.

Inter-Module Bus (IMB)

A proprietary high-speed bus used by the Broadcom ServerWorks chipsets. It runs at various speeds, depending on the chipset.

internal command

In DOS, a command contained in **COMMAND.COM** so that no other file must be loaded to perform the command. DIR and COPY are two examples of internal commands. In Windows, a command contained in **CMD.EXE**.

internal device

A peripheral device installed inside the main system case in either an expansion slot or a drive bay.

internal drive

A disk or tape drive mounted inside one of a computer's disk drive bays (or a hard disk card, which is installed in one of the computer's slots).

Internet

A computer network that joins many government, university, and private computers together over phone lines. The Internet traces its origins to a network set up in 1969 by the Department of Defense. You can connect to the Internet through many online services, such as CompuServe and America Online, or you can connect through local Internet service providers (ISPs). Internet computers use the TCP/IP communications protocol. Several million hosts exist on the Internet; a host is a mainframe, mini, or workstation that directly supports the Internet protocol (the IP in TCP/IP).

Internet Explorer (IE)

Microsoft's line of web browsers for Windows and Macintosh computers. Most websites are optimized to display best on systems running recent versions of IE.

interpreter

A program for a high-level language that translates and executes the program at the same time. The program statements that are interpreted remain in their original source language, the way the programmer wrote them—that is, the program does not need to be compiled before execution. Interpreted programs run more slowly than compiled programs and always must be run with the interpreter loaded in memory.

interrupt

A suspension of a process, such as the execution of a computer program, caused by an event external to that process and performed in such a way that the process can be resumed. An interrupt can be caused by internal or external conditions, such as a signal indicating that a device or program has completed a transfer of data. Hardware interrupts (also called IRQs) are used by devices, whereas software interrupts are used by programs. See also [IRQ](#).

interrupt vector

A pointer in a table that gives the location of a set of instructions the computer should execute when a particular interrupt occurs.

I0. SYS

One of the DOS/Windows 9x system files required to boot the machine. The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

IP address

An identifier for a computer or device on a TCP/IP network. The format of an IP address is a 32-bit numeric address written as four numbers separated by periods, in which each number can be 0-255. The TCP/IP protocol routes messages based on the IP address of the destination.

IPv6

A new version of the IP protocol that expands the range of IP addresses from 32 bits to 128 bits, which relieves the strain on the current universe of IP addresses. IPv6 is backward compatible with IPv4 to allow its gradual adoption.

IPX (internetwork packet exchange)

Novell NetWare's native LAN communications protocol (primarily in versions 4.x and earlier) used to move data between server and/or workstation programs running on different network nodes. IPX packets are encapsulated and carried by the packets used in Ethernet and the similar frames used in Token-Ring networks.

IrDA

An infrared communications standard established by the Infrared Data Association in 1993. IrDA is currently used primarily for data transfer between portable computers or to allow portable computers to print to a printer with an IrDA port.

IRQ (interrupt request)

Physical connections between external hardware devices and the interrupt controllers. When a device such as a floppy controller or a printer needs the attention of the CPU, an IRQ line is used to get the attention of the system to perform a task. On PC and XT IBM-compatible systems, eight IRQ lines are included, numbered IRQ0-IRQ7. On the AT and PS/2 systems, 16 IRQ lines are numbered IRQ0-IRQ15. IRQ lines must be used by only a single adapter in the ISA bus systems, but Micro Channel Architecture (MCA) adapters and most PCI-based systems can share interrupts. IRQ sharing with modern systems requires a system with PCI cards and Windows 95B or above. Windows 2000/XP are better at sharing IRQs than Windows 9x/Me. See also [virtual IRQ](#).

ISA (Industry Standard Architecture)

The bus architecture introduced as an 8-bit bus with the original IBM PC in 1981 and later expanded to 16 bits with the IBM PC/AT in 1984. ISA slots are occasionally found in PC systems today, but the latest chipsets have eliminated them.

ISA bus clock

Clock that normally operates the ISA bus at 8.33MHz.

iSCSI

Short for Internet SCSI, this is an implementation of SCSI that uses Ethernet networks using TCP/IP to transfer data in both directions between a server and a SCSI drive or drive array.

ISDN (Integrated Services Digital Network)

An international telecommunications standard that enables a communications channel to carry digital data simultaneously with voice and video information.

ISO (International Standards Organization)

The ISO, based in Paris, develops standards for international and national data communications. The U.S. representative to the ISO is the American National Standards Institute (ANSI). See also [High Sierra format](#).

ISO 9660

An international standard that defines file systems for CD-ROM discs, independent of the operating system. ISO (International Standards Organization) 9660 has two levels. Level one provides for DOS file system compatibility, whereas level two allows filenames of up to 32 characters. See also [High Sierra format](#).

ISP (Internet service provider)

A company that provides Internet access to computer users. Most ISPs originally provided dialup analog modem service only, but many ISPs now provide various types of broadband support for DSL, cable modem, or fixed wireless Internet devices. Some ISPs, such as America Online (AOL), also provide proprietary content.

Itanium

An Intel eighth-generation processor, codenamed Merced, it is the first 64-bit instruction PC processor from Intel. It features a new Explicitly Parallel Instruction Computing (EPIC) architecture for more performance when running optimized code. Also, it features internal L1/L2 and L3 error correcting code (ECC) caches to improve throughput and reliability. It was designed initially for the server or high-end workstation market. The improved Itanium 2 processor offers faster clock speeds and faster cache memory. See also [L3 cache](#).

ITU (International Telecommunications Union)

Formerly called CCITT. An international committee organized by the United Nations to set international communications recommendations which frequently are adopted as standards and to develop interface, modem, and data network recommendations. The Bell 212A standard for 1,200bps communication in North America, for example, is observed internationally as CCITT V.22. For 2,400bps communication, most U.S. manufacturers observe V.22bis, whereas V.32, V.32bis, V.34, and V.34+ are standards for 9,600bps, 14,400bps, 28,800bps, and 33,600bps, respectively. The V.90 standard recently was defined for 56Kbps modems.

J-lead

J-shaped leads on chip carriers, which can be surface-mounted on a PC board or plugged into a socket that then is mounted on a PC board, usually on .050" centers.

jabber

An error condition on an Ethernet-based network in which a defective network card or outside interference is constantly sending data, preventing the rest of the network from working.

Java

An object-oriented programming language and environment similar to C or C++. Java was developed by Sun Microsystems and is used to create network-based applications.

JavaScript

A scripting language developed by Netscape for web browsers. JavaScript can perform calculations and mouse rollovers, but it doesn't require the web browser to download additional files, as with Java.

Jaz drive

A proprietary type of removable media drive with a magnetic hard disk platter in a rigid plastic case. Developed by Iomega, Jaz drives were discontinued in 2002, but media is still available for both 1GB and 2GB versions of the drive.

JEDEC (Joint Electron Devices Engineering Council)

A group that establishes standards for the electronics industry. JEDEC established the original PC66 SDRAM standard.

Joliet

Microsoft extension of the ISO 9660 standard for recordable/rewritable CDs. Joliet is designed for use with 32-bit Windows versions that support long filenames, but it supports file/folder names up to 128 bytes (128 European or 64 Unicode characters) only. Some very long folder/filenames might need to be truncated when stored on a Joliet-format CD.

joule

The standard unit of electrical energy, it's frequently used to measure the effectiveness of surge suppressors.

joystick

An input device generally used for game software, usually consisting of a central upright stick that controls horizontal and vertical motion and one or more buttons to control discrete events, such as

firing guns. More complex models can resemble flight yokes and steering wheels or incorporate tactile feedback.

JPEG (Joint Photographic Experts Group)

The international consortium of hardware, software, and publishing interests which under the auspices of the ISO has defined a universal standard for digital compression and decompression of still images for use in computer systems. JPEG compresses at about a 20:1 ratio before visible image degradation occurs. A lossy data compression standard that was originally designed for still images but also can compress real-time video (30 frames per second) and animation. Lossy compression permanently discards unnecessary data, resulting in some loss of precision. Files stored in the JPEG format have the extension `.jpg` or `.jpeg`.

JScript

Microsoft's equivalent to JavaScript. See also [JavaScript](#).

jukebox

A type of CD-ROM drive that enables several CD-ROM discs to be in the drive at the same time. The drive itself determines which disc is needed by the system and loads the discs into the reading mechanism as needed.

jumper block

A small, plastic-covered metal clip that slips over two pins protruding from a circuit board. Sometimes also called a shunt. When in place, the jumper block connects the pins electrically and closes the circuit. By doing so, it connects the two terminals of a switch, turning it "on." Jumper blocks are commonly used to configure internal hard drives and motherboard settings.

K6

The popular line of Socket 7 and Super Socket 7 processors developed by AMD. Members included the K6, K6-2, and K6-III.

K56flex

A proprietary standard for 56Kbps modem transmissions developed by Rockwell and implemented in modems from a variety of vendors. Superseded by the official V.90 standard for 56Kbps modems. See also [X2](#), [V.90](#), and [V.92](#).

Kermit

A protocol designed for transferring files between microcomputers and mainframes. Developed by Frank DaCruz and Bill Catchings at Columbia University (and named after the talking frog on *The Muppet Show*), Kermit was widely accepted in the academic world before the advent of the Internet.

kernel

Operating system core component.

key disk

In software copy protection schemes popular during the 1980s, a distribution floppy disk that must be present in a floppy disk drive for an application program to run.

keyboard

The primary input device for most computers, consisting of keys with letters of the alphabet, digits, punctuation, and function control keys.

keyboard macro

A series of keystrokes automatically input when a single key is pressed.

keychain drive

A popular term for small solid-state devices using flash memory that connect to a PC through the USB port. Such devices are recognized as drive letters and have typical capacities ranging from 32MB to 128MB. Most have a fixed capacity, but some have provision for upgradeable memory with SD or other small-form-factor flash memory. Also known as *thumb* drives.

keylock

Physical locking mechanism to prevent internal access to the system unit or peripherals.

kibi

A multiplier indicating 1,024 of some unit. Abbreviated as Ki. See also [*gibi*](#).

kilo

A multiplier indicating one thousand (1,000) of some unit. Abbreviated as k or K. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,024. One kilobit, for example, equals 1,000 bits, whereas one kilobyte equals 1,024 bytes.

kilobyte (KB)

A unit of information storage equal to 1,000 bytes (decimal) or 1,024 bytes (binary). Binary KB are now called kibibytes. See also [*kibi*](#).

kludge

An inelegant but workable solution for a software or hardware problem.

KVM switch

Short for keyboard-video-mouse switch, it's a device that permits a single keyboard, display, and mouse to control two or more PCs or servers.

L1 cache (level one)

A memory cache built into the CPU core of 486 and later generation processors. See also [cache](#) and [disk cache](#).

L2 cache (level two)

A second-level memory cache external to the processor core, usually larger and slower than L1. Normally found on the motherboards of 386, 486, and Pentium systems and inside the processor packages or modules in Pentium Pro and later Intel processors, AMD K6-III processors, and Athlon and Duron processors. Cartridge-based caches used in the Pentium II, early Celeron, Pentium III, and Athlon processors run faster than motherboard cache but at speeds up to only one-half the CPU speed. Modern Socket 370, Socket A, and other socket-based processors contain the L2 cache inside the CPU die, enabling the L2 cache to work at the full speed of the processor. See also [SEC](#), [cache](#), and [disk cache](#).

L3 cache (level three)

A third-level memory cache external to the processor core. The only current Intel-compatible processors to include L3 cache are the Itanium and Itanium 2 processors from Intel. Depending on the model, these contain 2MB or 4MB of L3 cache that runs at full processor speed. If a motherboard provides L2 cache, such as many Super Socket 7 motherboards made for Pentium and Pentium-compatible processors, L2 cache becomes L3 cache if a processor with integrated L3 cache, such as the AMD K6-III, is used. Motherboard-based cache modules run at FSB speeds, which are much slower than on-chip or on-die processor speeds. See also [cache](#) and [disk cache](#).

LAN

Local area network; a network contained within a building. Both home and office networks are considered LANs. Ethernet, Fast Ethernet, Gigabit Ethernet, and Wireless Ethernet are used in office LANs, whereas home LANs might use Ethernet, Fast Ethernet, HomePNA, HomeRF, or Wi-Fi Wireless Ethernet.

landing zone

An unused track on a disk surface on which the read/write heads can land when power is shut off. The place a parking program or a drive with an autopark mechanism parks the heads.

LAPM (link-access procedure for modems)

An error-control protocol incorporated in CCITT Recommendation V.42. Similar to the MNP and HST protocols, it uses cyclic redundancy checking (CRC) and retransmission of corrupted data (ARQ) to ensure data reliability.

laptop computer

A computer system smaller than a briefcase but larger than a notebook that usually has a clamshell design in which the keyboard and display are on separate halves of the system, which are hinged together. These systems normally run on battery power. Many vendors use the terms notebook and laptop computer interchangeably.

large mode

A translation scheme used by the Award BIOS to translate the cylinder, head, and sector specifications of an IDE drive to those usable by an enhanced BIOS. It doesn't produce the same translated values as LBA mode and is not recommended because it is not supported by other BIOS vendors.

large-scale integration

See [LC](#).

laser printer

A type of printer that is a combination of an electrostatic copying machine and a computer printer. The output data from the computer is converted by an interface into a raster feed, similar to the impulses a TV picture tube receives. The impulses cause the laser beam to scan a small drum that carries a positive electrical charge. Where the laser hits, the drum is discharged. A toner, which also carries a positive charge, is then applied to the drum. This toner a fine, black powder sticks to only the areas of the drum that have been discharged electrically. As it rotates, the drum deposits the toner on a negatively charged sheet of paper. Another roller then heats and bonds the toner to the page. See also [LED printer](#).

latency

1) The amount of time required for a disk drive to rotate half a revolution. Represents the average amount of time to locate a specific sector after the heads have arrived at a specific track. Latency is part of the average access time for a drive. 2) The initial setup time required for a memory transfer in DRAM to select the row and column addresses for the memory to be read/written.

LBA (logical block addressing)

A method used with SCSI and IDE drives to translate the cylinder, head, and sector specifications of the drive to those usable by an enhanced BIOS. LBA is used with drives that are larger than 528MB and causes the BIOS to translate the drive's logical parameters to those usable by the system BIOS.

LCC (leadless chip carrier)

A type of integrated circuit package that has input and output pads rather than leads on its perimeter.

LCD (liquid crystal display)

A display that uses liquid crystal sealed between two pieces of polarized glass. The polarity of the liquid crystal is changed by an electric current to vary the amount of light that can pass through. Because LCD displays do not generate light, they depend on the reflection of ambient light or backlighting the screen. The best type of LCD, the active-matrix or thin-film transistor (TFT) LCD, offers fast screen updates and true color capability.

LED (light-emitting diode)

A semiconductor diode that emits light when a current is passed through it.

LED printer

A printer that uses an LED instead of a laser beam to discharge the drum.

legacy port

I/O ports used on systems before the development of the multipurpose USB port. Serial, parallel, keyboard, and PS/2 mouse ports are legacy ports.

letterbox

Refers to how wide-screen movies are displayed on TV or monitor screens with normal aspect ratios of 4:3. Because wide-screen movies have aspect ratios as high as 16:9, the wide-screen image leaves blank areas at the top and bottom of the screen. See also [*aspect ratio*](#).

LGA (land grid array)

A type of chip socket that moves the pins from the processor to the motherboard. The pins (*lands*) connect to pads on the back side of the processor. The first LGA design is Socket 775.

LIF (low insertion force)

A socket that requires only a minimum of force to insert a chip carrier.

light pen

A handheld input device with a light-sensitive probe or stylus connected to the computer's graphics adapter board by a cable. Used for writing or sketching onscreen or as a pointing device for making selections. Unlike mice, it's not widely supported by software applications.

line-interactive UPS

A UPS design that uses an two-way AC/DC inverter to charge the battery and provide power from the battery after AC power fails. It's the simplest type of UPS suitable for server use.

line voltage

The AC voltage available at a standard wall outlet, nominally 110V120V in North America and 220V230V in Europe and Japan.

linear tape-open (LTO)

A family of open standards for tape backups whose first products were introduced in mid-2000. LTO was jointly developed by Seagate, IBM, and Hewlett-Packard. Ultrium format products have capacities of up to 800GB (2:1 compression). The faster but smaller-capacity Accelis format was never manufactured. See also [Ultrium](#).

lithium-ion

A portable system battery type that is longer-lived than either NiCad or NiMH technologies, can't be overcharged, and holds a charge well when not in use. Lithium-ion batteries are also lighter weight than the NiCad and NiMH technologies. Because of these superior features, Li-ion batteries have come to be used in all but the very low end of the portable system market.

local area network (LAN)

The connection of two or more computers, usually via a network adapter card or NIC.

local bus

A generic term used to describe a bus directly attached to a processor that operates at the processor's speed and data-transfer width.

local echo

A modem feature that enables the modem to send copies of keyboard commands and transmitted data to the screen. When the modem is in command mode (not online to another system), the local echo usually is invoked through an ATE1 command, which causes the modem to display the user's typed commands. When the modem is online to another system, the local echo is invoked by an ATFO command, which causes the modem to display the data it transmits to the remote system.

logical drive

A drive as named by a DOS drive specifier, such as C: or D:. Under DOS 3.3 or later, a single physical drive can act as several logical drives, each with its own specifier. A primary partition can contain only one logical drive; an extended partition can contain one or more logical drives. See also [extended partition](#) and [primary partition](#).

logical unit number

See [LUN](#).

lossless compression

A compression technique that preserves all the original information in an image or other data structures. PKZIP and Microsoft CAB files are popular applications of lossless compression.

lossless linking

A technique used by DVD+RW drives to enable the DVD+RW video writing process to pause and continue as data is available. Lossless linking enables DVD+RW video media to be read by standalone DVD video players and DVD-ROM drives.

lossy compression

A compression technique that achieves optimal data reduction by discarding redundant and unnecessary information in an image. MP3, MPEG, and JPEG are popular examples of lossy compression.

lost clusters

Clusters that have been marked accidentally as "unavailable" in the FAT even though they don't belong to any file listed in a directory. See also [cluster](#).

low-level formatting

Formatting that divides tracks into sectors on the platter surfaces. Places sector-identifying information before and after each sector and fills each sector with null data (usually hex F6). Specifies the sector interleave and marks defective tracks by placing invalid checksum figures in each sector on a defective track.

LPT port

Line printer port, a common system abbreviation for a parallel printer port. Common LPT port numbers range from LPT1 to LPT3.

LPX

A semiproprietary motherboard design used in many Low Profile or Slimline case systems. Because no formal standard exists, these typically are not interchangeable between vendors and are often difficult to find replacement parts for or upgrade.

luminance

Measure of brightness usually used in specifying monitor brightness.

LUN (logical unit number)

A number given to a device (a logical unit) attached to a SCSI physical unit and not directly to the SCSI bus. Although as many as eight logical units can be attached to a single physical unit, a single logical unit typically is a built-in part of a single physical unit. A SCSI hard disk, for example, has a built-in SCSI bus adapter that is assigned a physical unit number or SCSI ID, and the controller and drive portions of the hard disk are assigned a LUN (usually 0). See also [PUN](#).

LZW (Lempel Zev Welch)

A lossless compression scheme used in the GIF and TIFF graphic formats, named after its co-creators, Abraham Lempel, Jacob Ziv, and Terry Welch.

MAC address

Short for Media Access Control address, this is a unique hardware number assigned to network hardware, such as NICs and routers. The MAC address assigned to the WAN side of some broadband Internet routers can be changed to equal the MAC address of the NIC previously used to attach to a broadband device, such as a cable modem.

machine address

A hexadecimal (hex) location in memory.

machine language

Hexadecimal program code a computer can understand and execute. It can be output from the assembler or compiler.

macro

A series of commands in an application that can be stored and played back on demand. Many applications from various vendors support Microsoft Visual Basic for Applications as their macro language.

macro virus

A computer virus that uses a scripting language to infect Microsoft Word document templates or email systems.

magnetic domain

A tiny segment of a track just large enough to hold one of the magnetic flux reversals that encode data on a disk surface.

magneto-optical recording

An erasable optical disk recording technique that uses a laser beam to heat pits on the disk surface to the point at which a magnet can make flux changes.

magneto-resistive

A technology originally developed by IBM and commonly used for the read element of a read/write head on a high-density magnetic disk. Based on the principle that the resistance to electricity changes in a material when brought into contact with a magnetic field, in this case, the read element material and the magnetic bit. Such drives use a magneto-resistive read sensor for reading and a standard inductive element for writing. A magneto-resistive read head is more sensitive to magnetic fields than inductive read heads. Giant magneto-resistive heads are an improved version that store more data in the same space.

mainframe

A somewhat vague distinction that identifies any large computer system normally capable of supporting many users and programs simultaneously.

mask

A photographic map of the circuits for a particular layer of a semiconductor chip used in manufacturing the chip.

master boot record (MBR)

On hard disks, a one-sector-long record that contains the master boot program as well as the master partition table containing up to four partition entries. The master boot program reads the master partition table to determine which of the four entries is active (bootable) and then loads the first sector of that partition, called the volume boot record. The master boot program tests the volume boot record for a 55AAh signature at offset 510; if it's present, program execution is transferred to the volume boot sector, which typically contains a program designed to load the operating system files. The MBR is always the first physical sector of the disk, at Cylinder 0, Head 0, Sector 1. Also called master boot sector.

math coprocessor

A processing chip designed to quickly handle complex arithmetic computations involving floating-point arithmetic, offloading these from the main processor. Originally contained in a separate coprocessor chip, starting with the 486 family of processors. Intel now has incorporated the math coprocessor into the main processors in what is called the floating-point unit.

MCA (Micro Channel Architecture)

Developed by IBM for the PS/2 line of computers and introduced on April 2, 1987. Features include a 16- or 32-bit bus width and multiple master control. By allowing several processors to arbitrate for resources on a single bus, the MCA is optimized for multitasking, multiprocessor systems. Offers

switchless configuration of adapters, which eliminates one of the biggest headaches of installing older adapters. MCA systems became obsolete after the development of the PCI bus.

MCGA (multicolor graphics array)

A type of PC video display circuit introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80x25 characters in 16 colors with a character box of 8x16 pixels. Graphics are supported at a maximum resolution of 320x200 pixels in 256 (from a palette of 262,144) colors or 640x480 pixels in two colors. The MCGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz and supports analog color or analog monochrome displays.

MCH (memory controller hub)

Intel's term for the chip used in its 8xx-series chipsets to connect the processor with high-bandwidth devices such as memory, video, and the system bus, replacing the North Bridge chip. MCH chips connect with the I/O controller hub (the 8xx chipsets' replacement for the South Bridge) through a high-speed hub interface. See also [ICH](#).

MCI (media control interface)

A device-independent specification for controlling multimedia devices and files. MCI is a part of the multimedia extensions and offers a standard interface set of device control commands. MCI commands are used for audio recording and playback and animation playback. Device types include CD audio, digital audio tape players, scanners, MIDI sequencers, videotape players or recorders, and audio devices that play digitized waveform files.

MDA (monochrome display adapter; also, MGAmono graphics adapter)

A type of PC video display adapter introduced by IBM on August 12, 1981, that supports text only. Text is supported at a maximum resolution of 80x25 characters in four colors with a character box of 9x14 pixels. Colors, in this case, indicate black, white, bright white, and underlined. Graphics modes are not supported. The MDA outputs a digital signal with a horizontal scanning frequency of 18.432KHz and supports TTL monochrome displays. The IBM MDA card also includes a parallel printer port.

mean time between failure

See [MTBF](#).

mean time to repair

See [MTTR](#).

MEB

Mid-Level Electronics Bay. An SSI form factor originally developed for use with slot-based server processors, now used for four-way and larger designs. Sometimes erroneously referred to as *EEB*

3.5.

mebi

A multiplier indicating 1,048,576 of a unit of measurement.

mebibyte (Mi)

A unit of information storage equal to 1,048,576 bytes (1,024x1,024 equals 1Mi). This value was previously called a binary megabyte. See also [megabyte](#) and [kilobyte](#).

medium

The magnetic coating or plating that covers a disk or tape.

mega

A multiplier indicating one million (1,000,000) of some unit. Abbreviated as m or M. Traditionally, mega has also been defined as 1,048,576 (1,024 kilobytes, where kilobyte equals 1,024) in applications such as memory sizing or disk storage (as defined by many BIOSs and by FDISK and other disk preparation programs). The term mebi is now used for 1,048,576. See also [mebi](#).

megabyte (MB)

A unit of information storage equal to 1,000,000 bytes. Also called a decimal megabyte. The value 1,048,576 bytes has been called a binary megabyte but is now known as a mebibyte. See also [mebibyte](#).

megapixel

A unit of digital camera resolution equal to approximately 1,000,000 pixels. A one-megapixel camera has a resolution of approximately 1,152x864; a two-megapixel camera has a resolution of approximately 1,760x1,168. Finally, a three-megapixel camera has a resolution of approximately 2,160x1,440. One-megapixel or lower-resolution cameras are suitable for 4"x6" or smaller snapshots only, whereas two-megapixel cameras produce excellent 5"x7" enlargements and acceptable 8"x10" enlargements. Three-megapixel or higher-resolution cameras produce excellent 8"x10" and 11"x14" enlargements. The higher the megapixel rating, the more flash memory space is used by each picture and the longer it takes each picture to be recorded to flash memory.

memory

Any component in a computer system that stores information for future use.

memory caching

A service provided by extremely fast memory chips that keeps copies of the most recent memory accesses. When the CPU makes a subsequent access, the value is supplied by the fast memory

rather than by the relatively slow system memory. L1 and L2 caches are memory caches found on most recent processors. See also [L1 cache](#), [L2 cache](#), and [L3 cache](#).

memory scrubbing

A task performed by many servers that repeatedly reads memory contents during idle time and corrects errors when possible. Noncorrectable errors are reported to the server management software so the defective module can be replaced.

Memory Stick

A Sony-developed flash memory device that's about the size of a stick of gum. It is used by digital cameras, camcorders, digital music players, and voice recorders primarily those made by Sony.

memory-resident program

A program that remains in memory after it has been loaded, consuming memory that otherwise might be used by application software.

menu software

Utility software that makes a computer running DOS easier to use by replacing DOS commands with a series of menu selections.

MESI

Short for modified exclusive shared invalid, it's a cache coherency protocol used by Intel processors.

MFM encoding (modified frequency modulation encoding)

A method of encoding data on the surface of a disk. The coding of a bit of data varies by the coding of the preceding bit to preserve clocking information. Used only by floppy drives today because it stores less data than other types of encoding such as RLL. See also [RLL](#).

MHz

An abbreviation for megahertz, a unit of measurement indicating the frequency of one million cycles per second. One hertz (Hz) is equal to one cycle per second. Named after Heinrich R. Hertz, a German physicist who first detected electromagnetic waves in 1883.

MI/MIC (mode indicate/mode indicate common)

Also called forced or manual originate. Provided for installations in which equipment other than the modem does the dialing. In such installations, the modem operates in dumb mode (no auto-dial capability), yet must go off-hook in originate mode to connect with answering modems.

micro (μ)

A prefix indicating one millionth ($1/1,000,000$ or $.000001$) of some unit.

micron

A unit of measurement equaling one millionth of a meter. Often used in measuring the size of circuits in chip manufacturing processes. Current state-of-the-art chip fabrication builds chips with 0.13 to 0.15-micron circuits.

microprocessor

A solid-state central processing unit much like a computer on a chip. An integrated circuit that accepts coded instructions for execution.

microsecond (μ s)

A unit of time equal to one millionth ($1/1,000,000$ or $.000001$) of a second.

MIDI (musical instrument digital interface)

An interface and file format standard for connecting a musical instrument to a microcomputer and storing musical instrument data. Multiple musical instruments can be daisy-chained and played simultaneously with the help of the computer and related software. The various operations of the instruments can be captured, saved, edited, and played back. A MIDI file contains note information, timing (how long a note is held), volume, and instrument type for as many as 16 channels. Sequencer programs are used to control MIDI functions such as recording, playback, and editing. MIDI files store only note instructions and not actual sound data. MIDI files can be played back by virtually all sound cards, but old sound cards might use FM synthesis to imitate the musical instruments called for in the MIDI file. Recent sound cards use stored musical instrument samples for more realistic MIDI playback.

MII

A Socket 7-compatible processor originally developed by Cyrix and now sold by VIA Technologies as the VIA Cyrix MII.

milli (m)

A prefix indicating one thousandth ($1/1,000$ or $.001$) of some unit.

millisecond (ms)

A unit of time equal to one thousandth ($1/1,000$ or $.001$) of a second.

MIME (Multipurpose Internet Mail Extensions)

Allows Internet and email services to exchange binary files and select the proper program to open the file after it's received.

minitower

A type of PC system case that is shorter than a full- or mid-sized tower. Most low-cost computers sold at retail stores use the minitower case combined with a Micro-ATX motherboard.

MIPS (million instructions per second)

Refers to the average number of machine-language instructions a computer can perform or execute in one second. Because various processors can perform different functions in a single instruction, MIPS should be used only as a general measure of performance among various types of computers.

MMX

An Intel processor enhancement that adds 57 new instructions designed to improve multimedia performance. MMX also implies a doubling of the internal L1 processor cache on Pentium MMX processors compared to non-MMX Pentium processors. Later processors also include MMX along with other multimedia instructions.

mnemonic

An abbreviated name for something used in a manner similar to an acronym. Computer processor instructions are often abbreviated with a mnemonic, such as JMP (jump), CLR (clear), STO (store), and INIT (initialize). A mnemonic name for an instruction or an operation makes it easy to remember and convenient to use.

MNP (Microcom Networking Protocol)

Asynchronous error-control and data-compression protocols developed by Microcom, Inc., and now in the public domain. They ensure error-free transmission through error detection (CRC) and retransmission of erred frames. MNP Levels 14 cover error control and have been incorporated into CCITT Recommendation V.42. MNP Level 5 includes data compression but is eclipsed in superiority by V.42bis an international standard that is more efficient. Most high-speed modems connect with MNP Level 5 if V.42bis is unavailable. MNP Level 10 provides error correction for impaired lines and adjusts to the fastest possible speed during connection. MNP Level 10EC is an improved version of MNP Level 10, adding more reliability and support for cellular phone hand-offs.

MO (magneto-optical)

MO drives use both magnetic and optical storage properties. MO technology is erasable and recordable, as opposed to CD-ROM (read-only) and WORM (write-once) drives. MO uses laser and magnetic field technology to record and erase data.

mobile module (MMO)

A type of processor packing from Intel for mobile computers consisting of a Pentium or newer

processor mounted on a small daughterboard along with the processor voltage regulator, system's L2 cache memory, and North Bridge part of the motherboard chipset.

modem (modulator/demodulator)

A device that converts electrical signals from a computer into an audio form transmittable over telephone lines, or vice versa. It modulates, or transforms, digital signals from a computer into the analog form that can be carried successfully on a phone line; it also demodulates signals received from the phone line back to digital signals before passing them to the receiving computer. To avoid confusion with other types of Internet connection devices such as cable modems, modems are often called analog modems or dialup modems.

modulation

The process of modifying some characteristic of a carrier wave or signal so that it varies in step with the changes of another signal, thus carrying the information of the other signal.

module

An assembly that contains a complete circuit or subcircuit.

MOESI

Short for modified owned exclusive shared invalid, it's a cache coherency protocol used by AMD Opteron processors.

monitor

See [*display*](#).

monochrome display adapter

See [*MDA*](#).

MOS (metal-oxide semiconductor)

Refers to the three layers used in forming the gate structure of a field-effect transistor (FET). MOS circuits offer low-power dissipation and enable transistors to be jammed closely together before a critical heat problem arises. PMOS, the oldest type of MOS circuit, is a silicon-gate P-channel MOS process that uses currents made up of positive charges. NMOS is a silicon-gate N-channel MOS process that uses currents made up of negative charges and is at least twice as fast as PMOS. CMOS, complementary MOS, is nearly immune to noise, runs off almost any power supply, and is an extremely low-power circuit technique.

motherboard

The main circuit board in the computer. Also called planar, system board, or backplane.

mouse

An input device invented by Douglas Engelbart of Stanford Research Center in 1963 and popularized by Xerox in the 1970s. A mechanical mouse consists of a roller ball and a tracking mechanism on the underside that relays the mouse's horizontal and vertical position to the computer, allowing precise control of the pointer location onscreen. The top side features two or three buttons and possibly a small wheel used to select or click items onscreen. Old-style optical mice sold in the 1980s used a single optical sensor and a grid-marked pad as an alternative to the roller ball. The latest optical mice use two optical sensors and can be moved across virtually any nonmirrored surface.

MPC

A trademarked abbreviation for Multimedia Personal Computer. The original MPC specification was developed by Tandy Corporation and Microsoft as the minimum platform capable of running multimedia software. In the summer of 1995, the MPC Marketing Council introduced an upgraded MPC 3 standard. The MPC 1 Specification defines the following minimum standard requirements: a 386SX or 486 CPU; 2MB RAM; 30MB hard disk; VGA video display; 8-bit digital audio subsystem; CD-ROM drive; and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 or later. The MPC 2 specification defines the following minimum standard requirements: 25MHz 486SX with 4MB RAM; 160MB hard disk; 16-bit sound card; 65,536-color video display; double-speed CD-ROM drive; and systems software compatible with the APIs of Microsoft Windows version 3.1 or later. The MPC 3 Specification defines the following minimum standard requirements: 75MHz Pentium with 8MB RAM; 540MB hard disk; 16-bit sound card; 65,536-color video display; quad-speed CD-ROM drive; OM-1compliant MPEG-1 video, and systems software compatible with the APIs of Microsoft Windows version 3.1 and DOS 6.0 or later. Virtually all computers sold since 1995 exceed MPC 3 standards.

MPEG (Motion Picture Experts Group)

A working ISO committee that has defined standards for lossy digital compression and decompression of motion video/audio for use in computer systems. The MPEG-1 standard delivers decompression data at 1.2Mbps1.5Mbps, enabling CD players to play full-motion color movies at 30 frames per second. MPEG-1 compresses at about a 50:1 ratio before image degradation occurs, but compression ratios as high as 200:1 are attainable. MPEG-2 extends to the higher data rates (2Mbps15Mbps) necessary for signals delivered from remote sources (such as broadcast, cable, or satellite). MPEG-2 is designed to support a range of picture aspect ratios, including 4:3 and 16:9. MPEG compression produces about a 50% volume reduction in file size. MP3 (the audio layer portion of the MPEG-1 standard) provides a wide range of compression ratios and file sizes for digital music storage, making it the de facto standard for exchanging digital music through sites such as Napster and its many rivals. See also [lossy compression](#).

MPR

The Swedish government standard for maximum video terminal radiation. The current version is called MPR II, but most monitors also comply with the newer and more restrictive TCO standards. See also [TCO](#).

MSDOS. SYS

One of the DOS/Windows 9x system files required to boot the machine. Contains the primary DOS routines. Loaded by **IO.SYS**, it in turn loads **COMMAND.COM**.

Mt. Rainier

An emerging standard for CD-RW and DVD+RW drives that provides for native operating system support of CD-RW and rewriteable DVD media. Drives and operating systems that support the Mt. Rainier standard (www.mt-rainier.org) can read or write Mt. Rainierformatted CD-R/RW or DVD+R/RW media without the need for proprietary packet-reading software such as Roxio's UDF Volume Reader for DirectCD-formatted media (www.roxio.com).

MTBF (mean time between failure)

A statistically derived measure of the probable time a device will continue to operate before a hardware failure occurs, usually given in hours. Because no standard technique exists for measuring MTBF, a device from one manufacturer can be significantly more or significantly less reliable than a device with the same MTBF rating from another manufacturer.

MTTR (mean time to repair)

A measure of the probable time it will take a technician to service or repair a specific device, usually given in hours.

Multichannel Multipoint Distribution Service (MMDS)

The most common form of so-called "wireless cable TV," MMDS is also used for two-way wireless Internet service. One of the leading MMDS technology manufacturers is Navini Networks (www.navini.com).

multicolor graphics array

See [MCGA](#).

multimedia

The integration of sound, graphic images, animation, motion video, and text in one environment on a computer. It is a set of hardware and software technologies that is rapidly changing and enhancing the computing environment.

multisession

A term used in CD-ROM recording to describe a recording event. Multisession capabilities allow data recording on the disk at various times in several recording sessions. Kodak's Photo CD is an example of multisession CD-R technology. See also [session \(single or multisession\)](#).

multitask

To run several programs simultaneously.

multithread

To concurrently process more than one message by an application program. OS/2 and 32-bit versions of Windows are examples of multithreaded operating systems. Each program can start two or more threads, which carry out various interrelated tasks with less overhead than two separate programs would require.

multiuser system

A system in which several computer terminals share the same central processing unit (CPU).

nano (n)

A prefix indicating one billionth ($1/1,000,000,000$ or .000000001) of some unit.

nanosecond (ns)

A unit of time equal to one billionth ($1/1,000,000,000$ or .000000001) of a second.

NetBEUI (NetBIOS Extended User Interface)

A network protocol used primarily by Windows NT and Windows 9x and most suitable for small peer-to-peer networks. NetBEUI is not supported by Microsoft in Windows XP and above but can still be manually installed for use in troubleshooting computers.

NetBIOS (Network Basic Input/Output System)

A commonly used network protocol originally developed by IBM and Sytek for PC local area networks. NetBIOS provides session and transport services (Layers 4 and 5 of the OSI model).

NetWare

Novell's server-based network for large businesses. NetWare 5 and NetWare 6 are designed to work well with IP-based networks.

network

A system in which several independent computers are linked to share data and peripherals, such as hard disks and printers.

network attached storage (NAS)

A hard disk-based storage device or array that plugs into the network and has its own IP address.

network interface card (NIC)

An adapter that connects a PC to a network.

Network Layer

In the OSI reference model, the layer that switches and routes the packets as necessary to get them to their destinations. This layer is responsible for addressing and delivering message packets. See also [OSI](#).

NiCad

The oldest of the three battery technologies used in portable systems, nickel cadmium batteries are rarely used in portable systems today because of their shorter life and sensitivity to improper charging and discharging. See also [NiMH](#) and [lithium-ion](#).

NiMH

A battery technology used in portable systems. Nickel metal-hydride batteries have approximately a 30% longer life than NiCads, are less sensitive to the memory effect caused by improper charging and discharging, and do not use the environmentally dangerous substances found in NiCads. Newer lithium-ion (Li-ion) batteries are far superior. NiMH batteries can sometimes be used in place of NiCads.

NLX

A new low-profile motherboard form factor standard that is basically an improved version of the semiproprietary LPX design. It's designed to accommodate larger processor and memory form factors and incorporate newer bus technologies, such as AGP and USB. Besides design improvements, it is fully standardized, which means you should be able to replace one NLX board with another from a different manufacturersomething that was not normally possible with LPX.

node

A device on a network. Also any junction point at which two or more items meet.

noise

Any unwanted disturbance in an electrical or mechanical system.

noninterlaced monitor

A desirable monitor design in which the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the entire screen in one pass. Virtually all CRTs sold recently for desktop use are noninterlaced.

nonvolatile memory (NVRAM)

Random-access memory whose data is retained when power is turned off. ROM/EPROM/EEPROM (flash) memory are examples of nonvolatile memory. Sometimes NVRAM is retained without any power whatsoever, as in EEPROM or flash memory devices. In other cases, the memory is maintained by a small battery. NVRAM that is battery maintained is sometimes also called CMOS memory (although CMOS RAM technically is volatile). CMOS NVRAM is used in IBM-compatible systems to store configuration information. True NVRAM often is used in intelligent modems to store a user-defined default configuration loaded into normal modem RAM at power-up.

nonvolatile RAM disk

A RAM disk powered by a battery supply so that it continues to hold its data during a power outage.

North Bridge

The Intel term for the main portion of the motherboard chipset that incorporates the interface between the processor and the rest of the motherboard. The North Bridge contains the cache, main memory, and AGP controllers, as well as the interface between the high-speed (normally 66MHz or 100MHz) processor bus and the 33MHz PCI (peripheral component interconnect) or 66MHz AGP (accelerated graphics port) buses. The functional equivalent of the North Bridge on the latest 8xx-series chipsets from Intel is the MCH. See also [chipset](#), [ICH](#), [MCH](#), and [South Bridge](#).

notebook computer

A very small personal computer approximately the size of a notebook.

NTSC

The National Television Standards Committee, which governs the standard for television and video playback and recording in the United States. The NTSC was originally organized in 1941 when TV broadcasting first began on a wide scale in black and white, and the format was revised in 1953 for color. The NTSC format has 525 scan lines, a field frequency of 60Hz, a broadcast bandwidth of 4MHz, a line frequency of 15.75KHz, a frame frequency of 1/30 of a second, and a color subcarrier frequency of 3.58MHz. It is an interlaced signal, which means it scans every other line each time the screen is refreshed. The signal is generated as a composite of red, green, and blue signals for color and includes an FM frequency for audio and a signal for stereo. See also [PAL](#) and [SECAM](#), which are incompatible systems used in Europe. NTSC is also called composite video.

null modem

A serial cable wired so that two data terminal equipment (DTE) devices, such as personal computers, or two data communication equipment (DCE) devices, such as modems or mice, can be connected. Also sometimes called a modem-eliminator or a LapLink cable. To make a null-modem cable with DB-25 connectors, you wire these pins together: 1-1, 2-3, 3-2, 4-5, 5-4, 6-8-20, 20-8-6, and 7-7.

numeric coprocessor

See [math coprocessor](#).

NVRAM (nonvolatile random access memory)

Memory that retains data without power. Flash memory and battery-backed CMOS RAM are examples of NVRAM.

object hierarchy

Occurs in a graphical program when two or more objects are linked and one object's movement is dependent on the other object. This is known as a parent-child hierarchy. In an example using a human figure, the fingers would be child objects to the hand, which is a child object to the arm, which is a child to the shoulder, and so on. Object hierarchy provides much control for an animator in moving complex figures.

OC (optical carrier) rates

Various data rates for optical fiber used in Internet backbones, based on the OC-1 rate of 51.84Mbps. Multiply the OC rate by 51.84Mbps to derive the data rate. For example, OC-12 is 622.08Mbps (51.84x12).

Occam's Razor

Also spelled Ockham's Razor; popular name for the principle that the simplest explanation is usually the correct one a very useful principle in computer troubleshooting.

OCR (optical character recognition)

An information-processing technology that converts human-readable text into computer data. Usually a scanner is used to read the text on a page, and OCR software converts the images to characters. Advanced OCR programs, such as OmniPage, can also match fonts, re-create page layouts, and scan graphics into machine-readable form.

ODI (Open Data-link Interface)

A device driver standard from Novell that enables multiple protocols to run on the same network adapter card. ODI adds functionality to Novell's NetWare and network computing environments by supporting multiple protocols and drivers.

OEM (original equipment manufacturer)

Any manufacturer who sells its product to a reseller. Usually refers to the original manufacturer of a particular device or component. Most HP hard disks, for example, are made by Seagate Technologies, who is considered the OEM. OEM products often differ in features from retail products and can have very short warranty periods if purchased separately from their intended use.

OLE (object linking and embedding)

An enhancement to the original Dynamic Data Exchange (DDE) protocol that enables the user to embed or link data created in one application to a document created in another application and subsequently edit that data directly from the final document.

online fallback

A feature that enables high-speed error-control modems to monitor line quality and fall back to the next lower speed if line quality degrades. Some modems fall forward as line quality improves.

open architecture

A system design in which the specifications are made public to encourage third-party vendors to develop add-on products. The PC is a true open architecture system, but the Macintosh is proprietary.

operating system (OS)

A collection of programs for operating the computer. Operating systems perform housekeeping tasks, such as input and output between the computer and peripherals and accepting and interpreting information from the keyboard. Windows XP and MacOS X are examples of popular OSs.

Opteron

An AMD single-core and dual-core processor built for workstation and server tasks. Opteron supports AMD64 64-bit extensions. It can be scaled to eight-way operation and beyond, and it uses Socket 940. Dual-core versions of Opteron can be installed in existing systems built for single-core processors after a BIOS update. See also [AMD64](#) and [Socket 940](#).

optical disk

A disk that encodes data as a series of reflective pits that are read (and sometimes written) by a laser beam.

Orange Book

The standards for recordable (CD-R) and rewritable (CD-RW) compact discs.

originate mode

A state in which the modem transmits at the predefined low frequency of the communications channel and receives at the high frequency. The transmit/receive frequencies are the reverse of the called modem, which is in answer mode. See also [answer mode](#).

OS/2

An operating system originally developed through a joint effort by IBM and Microsoft Corporation and later by IBM alone. Originally released in 1987, OS/2 is a 32-bit operating system designed to run on computers using the Intel 386 or later microprocessors. The OS/2 Workplace Shell, an integral part of the system, is a graphical interface similar to Microsoft Windows and the Apple Macintosh system. OS/2 Warp 4 is the most recent one and is used primarily as a server or in back-office functions today.

OSI (Open Systems Interconnection)

A reference model developed by the International Organization for Standardization (ISO) in the 1980s, the OSI model splits a computer's networking stack into seven discrete layers. Each layer provides specific services to the layers above and below it. From the top down, the Application Layer is responsible for program-to-program communication; the Presentation Layer manages data representation conversions. Next, the Session Layer is responsible for establishing and maintaining communications channels, and the Transport Layer is responsible for the integrity of data transmission. The Network Layer routes data from one node to another, the Data Link Layer is responsible for physically passing data from one node to another, and finally, the Physical Layer is responsible for moving data on and off the network media.

output

Information processed by the computer or the act of sending that information to a mass storage device, such as a video display, printer, or modem.

overclocking

The process of running a processor or video card at a speed faster than the officially marked speed by using a higher clock multiplier, faster bus speed, or faster core clock speed. Not recommended or endorsed by processor or video card manufacturers. See also [clock multiplier](#).

OverDrive

An Intel trademark name for its line of upgrade processors for 486, Pentium, and Pentium Pro systems. Although Intel no longer sells OverDrive processors, similar products are available from Evergreen Technologies and PowerLeap Products, Inc., for these processors plus Pentium II, Pentium III, Pentium 4, and Celeron-based systems.

overlay

Part of a program loaded into memory only when it is required.

overrun

A situation in which data moves from one device more quickly than a second device can accept it.

overscanning

A technique used in consumer display products that extends the deflection of a CRT's electron beam

beyond the physical boundaries of the screen to ensure that images always fill the display area.

overwrite

To write data on top of existing data, thus erasing the existing data.

package

A device that includes a chip mounted on a carrier and sealed.

packet

A message sent over a network that contains data and a destination address.

packet writing

A recording technique that sends data to a CD-R or CD-RW disc in multiple blocks, enabling normal writing processes in Windows Explorer to be used instead of a CD-mastering program. Compatible packet-reading software, such as Roxio's UDF Reader for DirectCD, must be used on systems that don't have a CD-R or CD-RW drive to enable the media to be read. See also [*Mt. Rainier*](#).

pairing

Combining processor instructions for optimal execution on superscalar processors.

PAL

1) Phase Alternating Line system. Invented in 1961, a system of TV broadcasting used in England and other European countries (except France). PAL's image format is 4:3, 625 lines, 50Hz, and 4MHz video bandwidth with a total 8MHz of video channel width. With its 625-line picture delivered at 25 frames per second, PAL provides a better image and an improved color transmission over the NTSC system used in North America. As a consequence, PAL and NTSC video tapes aren't interchangeable. 2) Programmable array logic, a type of chip that has logic gates specified by a device programmer.

palmtop computer

A computer system smaller than a notebook that is designed so it can be held in one hand while being operated by the other. Many are now called PDAs or personal digital assistants.

parallel

A method of transferring data characters in which the bits travel down parallel electrical paths simultaneously—for example, eight paths for 8-bit characters. Data is stored in computers in parallel form but can be converted to serial form for certain operations.

parity

A method of error checking in which an extra bit is sent to the receiving device to indicate whether an even or odd number of binary 1 bits was transmitted. The receiving unit compares the received information with this bit and can obtain a reasonable judgment about the validity of the character. The same type of parity (even or odd) must be used by two communicating computers, or both may omit parity. When parity is used, a parity bit is added to each transmitted character. The bit's value is 0 or 1, to make the total number of 1s in the character even or odd, depending on which type of parity is used. Parity checking isn't widely supported on recent systems, but memory with parity bits can be used as ECC memory on systems with ECC-compatible chipsets. See also [ECC](#).

park program

A program that executes a seek to the highest cylinder or just past the highest cylinder of a drive so the potential of data loss is minimized if the drive is moved. Park programs are not interchangeable between drives and are no longer required on most drives 40MB and above because these drives self-park their heads for safety.

partition

A section of a hard disk devoted to a particular operating system. Most hard disks have only one partition, devoted to DOS. A hard disk can have as many as four partitions, each occupied by a different operating system. DOS v3.3 or later can occupy two of these four partitions. A boot manager enables you to select the partition occupied by the operating system you want to start if you have multiple operating systems installed in different partitions. See also [boot manager](#).

Pascal

A high-level programming language named for the French mathematician Blaise Pascal (1623-1662). Developed in the early 1970s by Niklaus Wirth for teaching programming and designed to support the concepts of structured programming.

passive heatsink

A heatsink that does not include a fan. Passive heatsinks used on processors are usually larger than active heatsinks and rely on case fans to dissipate heat. Many North Bridge or memory control hubs on recent motherboards also use passive heatsinks.

passive matrix

Another name for dual-scan, display-type LCDs.

PC Card (PCMCIA Personal Computer Memory Card International Association)

A credit card-sized expansion adapter for notebook and laptop PCs. PC Card is the official PCMCIA trademark; however, both PC Card and PCMCIA card are used to refer to these standards. PCMCIA cards are removable modules that can hold numerous types of devices, including memory, modems, fax/modems, radio transceivers, network adapters, solid state disks, hard disks, and flash memory adapters.

PCI (Peripheral Component Interconnect)

A standard bus specification initially developed by Intel in 1992 that bypasses the standard ISA I/O bus and uses the system bus to increase the bus clock speed and take full advantage of the CPU's data path. The most common form of PCI is 32 bits wide running at 33MHz, but 66MHz and 64-bit wide versions of PCI are frequently used on servers.

PCI Express

A high-speed serial I/O interconnect standard being developed by the PCI-SIG (www.pcisig.com) as an eventual replacement for the original PCI standard. The initial version of PCI Express supports 0.8V signaling at 2.5GHz.

PCI-X (Peripheral Component Interconnect Extended)

A faster 64-bit version of PCI with speeds up to 133MHz. PCI-X is backward-compatible with PCI but also supports fault-tolerant features such as automatic reinitializing and disabling of faulty add-on cards.

PCL (Printer Control Language)

Developed by Hewlett-Packard in 1984 as a language for the HP LaserJet printer. PCL is now the de facto industry standard for PC printing. PCL defines a standard set of commands, enabling applications to communicate with HP or HP-compatible printers and is supported by virtually all printer manufacturers. Various levels of PCL are supported by HP and other brands of laser and inkjet printers.

PCM (pulse code modulation)

A technique for digitizing analog signals by sampling the signal and converting each sample into a binary number. Also stands for powertrain control module, which is what the computer in most modern automobiles is called.

PDA (personal digital assistant)

A handheld, palm-sized computer that functions primarily as a personal organizer and can be combined with a cellular phone or pager. Leading examples include the Palm series, Windowsbased PalmPCs, and the Handspring (which also runs the Palm OS).

PDF (portable document format)

Files with this extension can be read with the Adobe Acrobat Reader. See also [Acrobat](#).

pedestal

A server chassis that resembles a tower chassis but is wider, taller, and deeper to permit the use of

larger motherboards. Some pedestal server chassis include wheels, and some can be converted to a rack-mount form factor.

peer-to-peer

A type of network in which any computer can act as both a server (by providing access to its resources to other computers) and a client (by accessing shared resources from other computers).

pel

See [pixel](#).

Pentium

An Intel microprocessor with 32-bit registers, a 64-bit data bus, and a 32-bit address bus. The Pentium has a built-in L1 cache segmented into a separate 8KB cache for code and another 8KB cache for data. The Pentium includes an FPU or math coprocessor. It is backward compatible with the 486 and can operate in real, protected virtual, and virtual real modes. The MMX Pentium has a 16KB cache for code, has a 16KB cache for data, and adds the MMX instruction set.

Pentium 4

The first Intel seventh-generation processor, it's based on a new 32-bit microarchitecture that operates at higher clock speeds because of hyper pipelined technology, a rapid execution engine, a 400MHz system bus (later boosted to 533MHz and 800MHz), and an execution trace cache. The system bus runs at four times the processor bus speed. The floating-point and multimedia units have been improved by making the registers 128 bits wide and adding a separate register for data movement. Finally, SSE2 adds 144 new instructions for double-precision floating-point, SIMD integer, and memory management. The original Socket 423 version (Willamette) was later replaced by Socket 478 (Northwood) and finally by Socket 775 (Prescott) running at up to 3.6GHz. 800MHz system bus versions also support HT Technology.

Pentium 4 Extreme Edition

A high-speed version of the Pentium 4 that includes 2MB of L3 cache. The original versions ran at 3.46GHz and were made in Socket 478 and Socket 775. Later versions boosted the system bus from 800MHz to 1066MHz, used the Prescott core, and ran at 3.73MHz. It has been replaced by the Pentium Extreme Edition.

Pentium D

An Intel seventh-generation processor (code named Smithfield) that includes two Pentium 4 Prescott processor cores in the same processor die. The Pentium D fits into Socket 775 but uses different chipsets from the Pentium 4. The Pentium D includes EM64T architecture. See also [EM64T](#) and [AMD64](#).

Pentium Extreme Edition

A seventh-generation EM64T-compatible dual-core processor based on the Pentium D, but with HT Technology enabled. Dual-processor-enabled operating systems treat this chip as having four logical processors. Requires a different chipset from the Pentium D. See also [Pentium D](#), [EM64T](#), and [AMD64](#).

Pentium II

An Intel sixth-generation processor similar to the Pentium Pro but with MMX capabilities and SEC cartridge packaging technology. Includes L2 cache running at half-core speed.

Pentium III

An Intel sixth-generation processor similar to the Pentium II but with SSE (Streaming SIMD Extensions) added. Later PIII models (code-named Coppermine) include on-die L2 cache running at full core speed. It's available in both cartridge (Slot 1) and chip package (Socket 370) versions.

Pentium Pro

An Intel sixth-generation (P6) processor with 32-bit registers, a 64-bit data bus, and a 36-bit address bus. The Pentium Pro has the same segmented Level 1 cache as the Pentium but also includes a 256KB, 512KB, or 1MB of L2 cache on a separate die inside the processor package. The Pentium Pro includes an FPU or math coprocessor. It is backward compatible with the Pentium and can operate in real, protected, and virtual real modes. The Pentium Pro fits into Socket 8.

peripheral

Any piece of equipment used in computer systems that is an attachment to the computer. Disk drives, terminals, and printers are all examples of peripherals.

persistence

In a monitor, the quality of the phosphor chemical that indicates how long the glow caused by the electrons striking the phosphor will remain onscreen.

petabyte (P)

A measure of disk capacity equaling 1,000,000,000,000,000 bytes.

PGA

1) Pin grid array. A chip package that has a large number of pins on the bottom designed for socket mounting. 2) Professional graphics adapter. A limited-production, high-resolution graphics card for XT and AT systems from IBM.

phosphor

A layer of electroluminescent material applied to the inside face of a cathode-ray tube (CRT). When

bombarded by electrons, the material fluoresces, and after the bombardment stops it phosphoresces.

phosphorescence

The emission of light from a substance after the source of excitation has been removed.

Photo CD

A technology developed by Eastman Kodak and Philips that stores photographic images on a CD-R recordable compact disc. Images stored on the Photo CD can have resolutions as high as 2,048x3,072 pixels. Up to 100 true-color images (24-bit color) can be stored on one disc. Photo CD images are created by scanning film and digitally recording the images on compact discs. The digitized images are indexed (given a 4-digit code), and thumbnails of each image on the disc are shown on the front of the case along with its index number. Multisession capability enables several rolls of film to be added to a single disc on different occasions.

photolithography

The photographic process used in electronic chip manufacturing that creates transistors and circuit and signal pathways in semiconductors by depositing different layers of various materials on the chip.

photoresist

A chemical used to coat a silicon wafer in the semiconductor manufacturing process that makes the silicon sensitive to light for photolithography.

physical drive

A single disk drive. DOS defines logical drives, which are given a specifier, such as C: or D:. A single physical drive can be divided into multiple logical drives. Conversely, special software can span a single logical drive across two physical drives.

Physical Layer

See [*OSI*](#).

physical unit number

See [*PUN*](#).

PICMG

The PCI Industrial Computers Manufacturers Group is a trade association that develops standards for single-board and industrial computers. Its standards include AdvancedTCA, CompactPCI, and others. See also [*AdvancedTCA*](#) and [*CompactPCI*](#).

Picture CD

A simplified version of Photo CD that stores scanned images from a single roll of film on a CD-R disc. Images on Picture CDs, unlike those on Photo CDs, are stored in the industry-standard JPEG file format and can be opened with most photo-editing programs.

PIF (program information file)

A file that contains information about a non-Windows application specifying optimum settings for running the program under Windows 3.x. These are called property sheets in 32-bit Windows.

pin

1) The lead on a connector, chip, module, or device. 2) Personal identification number. A personal password used for identification purposes.

pin compatible

Chips having the same pinout functions. For example, a VIA C3 processor is pin compatible with an Intel Celeron (Socket 370 version).

pinout

A listing of which pins have which functions on a chip, socket, slot, or other connector.

PIO mode (programmed input/output mode)

The standard data transfer modes used by IDE drives that use the processor's registers for data transfer. This is in contrast with DMA modes, which transfer data directly between main memory and the device. The slowest PIO mode is 0, and the fastest PIO mode is mode 4 (16.66MBps). Faster modes use Ultra DMA transfers. See also [Ultra DMA](#).

pipeline

A path for instructions or data to follow.

pixel

A mnemonic term meaning picture element. Any of the tiny elements that form a picture on a video display screen. Also called a *pel*.

pixel shader

A small program that controls the appearance of individual pixels in a 3D image. Most recent mid-range and high-end GPUs such as NVIDIA's GeForce 3 and GeForce 4 Ti series and the ATI 8xxx and

9xxx series have built-in pixel shaders. See also [GPU](#), [hardware shader](#), and [vertex shader](#).

PKZIP

The original ZIP-format compression/decompression program developed by the late Phil Katz. His company, PKWARE, continues to develop PKZIP for popular operating systems, including Windows.

planar board

A term equivalent to motherboard, used by IBM in some of its literature.

plasma display

A display technology that uses plasma (electrically charged gas) to illuminate each pixel. Plasma displays are much thinner than conventional CRT displays but are much more expensive than CRTs or LCD displays. Several vendors now sell HDTV plasma displays that can also be connected to computers with VGA or DVI video connectors.

plated media

Hard disk platters plated with a form of thin metal film medium on which data is recorded.

platter

A disk contained in a hard disk drive. Most drives have two or more platters, each with data recorded on both sides.

PLCC (plastic leaded-chip carrier)

A chip-carrier package with J-leads around the perimeter of the package.

Plug and Play (PnP)

A hardware and software specification developed by Intel that enables a PnP system and PnP adapter cards to automatically configure themselves. PnP cards are free from switches and jumpers and are configured via the PnP BIOS in the host system, or via supplied programs for non-PnP systems. PnP also allows the system to detect and configure external devices, such as monitors, modems, and devices attached to USB or IEEE-1394 ports. Windows 9x, Me, 2000, and XP all support PnP devices.

polling

A communications technique that determines when a device is ready to send data. The system continually interrogates polled devices in a round-robin sequence. If a device has data to send, it sends back an acknowledgment and the transmission begins. Contrasts with interrupt-driven communications, in which the device generates a signal to interrupt the system when it has data to send. Polling enables two devices that would normally have an IRQ conflict to coexist because the

IRQ is not used for flow control.

port

Plug or socket that enables an external device, such as a printer, to be attached to the adapter card in the computer. Also a logical address used by a microprocessor for communication between it and various devices.

port address

One of a system of addresses used by the computer to access devices such as disk drives or printer ports. You might need to specify an unused port address when installing any adapter boards in a system unit.

port replicator

For mobile computers, a device that plugs into the laptop and provides all the ports for connecting external devices. The advantage of using a port replicator is that the external devices can be left connected to the replicator and the mobile computer connected to them all at once by connecting to the replicator, rather than connecting to each individual device. A port replicator differs from a docking station in that the latter can provide additional drive bays and expansion slots not found in port replicators. Traditionally, port replicators have plugged into a proprietary bus on the rear of a portable computer, but so-called universal models might attach to the PC Card (PCMCIA) slot or to a USB port.

portable computer

A computer system smaller than a transportable system but larger than a laptop system. Very few systems in this form factor are sold today, but companies such as Dolch still produce them. Most portable systems conform to the lunchbox style popularized by Compaq or the briefcase style popularized by IBM, each with a fold-down (removable) keyboard and built-in display. These systems characteristically run on AC power and not on batteries, include several expansion slots, and can be as powerful as full desktop systems.

POS (Programmable Option Select)

The Micro Channel Architecture's POS eliminates switches and jumpers from the system board and adapters by replacing them with programmable registers. Automatic configuration routines store the POS data in a battery-powered CMOS memory for system configuration and operations. The configuration utilities rely on adapter description files (ADF) that contain the setup data for each card.

POST (power on self test)

A series of tests run by the computer at power-on. Most computers scan and test many of their circuits and sound a beep from the internal speaker if this initial test indicates proper system performance.

PostScript

A page-description language developed primarily by John Warnock of Adobe Systems for converting and moving data to the laser-printed page. Instead of using the standard method of transmitting graphics or character information to a printer and telling it where to place dots one by one on a page, PostScript provides a way for the laser printer to interpret mathematically a full page of shapes and curves. Adobe Acrobat converts PostScript output files into files that can be read by users with varying operating systems. See also [Acrobat](#).

POTS (plain old telephone service)

Standard analog telephone service.

power factor conversion (PFC)

An expression of how efficient a power supply or UPS is at providing power. A device that provides 100% of its rated output has a PFC of 1.0. In practice, high-quality power supplies and UPS units have PFCs in the 90%-97% range (.90-.97 PFC).

power management

Systems used initially in mobile computers (and now also used in desktop systems) to decrease power consumption by turning off or slowing down devices during periods of inactivity. See also [APM](#).

power supply

An electrical/electronic circuit that supplies all operating voltage and current to the computer system.

PPGA (plastic pin grid array)

A chip-packaging form factor used by Intel as an alternative to traditional ceramic packaging.

PPP (Point-to-Point Protocol)

A protocol that enables a computer to use the Internet with a standard telephone line and high-speed modem. PPP has largely replaced the Serial Line Internet Protocol (SLIP) because it supports line sharing and error detection.

precompensation

A data write modification required by some older drives on the inner cylinders to compensate for the higher density of data on the (smaller) inner cylinders.

Presentation Layer

See [OSI](#).

primary partition

An ordinary, single-volume bootable partition. See also [extended partition](#).

printer

A device that records information visually on paper or other material.

processor

See [microprocessor](#).

processor speed

The clock rate at which a microprocessor processes data. A typical Pentium 4 processor, for example, operates at 2GHz (2 billion cycles per second).

program

A set of instructions or steps telling the computer how to handle a problem or task.

PROM (programmable read-only memory)

A type of memory chip that can be programmed to store information permanently; information that can't be erased. Also referred to as OTP for one-time programmable.

proprietary

Anything invented by one company and that uses components available from only that one company. Especially applies to cases in which the inventing company goes to lengths to hide the specifications of the new invention or to prevent other manufacturers from making similar or compatible items. The opposite of standard or open architecture. Computers with nonstandard components that are available from only the original manufacturer, such as Apple Macintosh systems, are known as proprietary.

protected mode

A mode available in all Intel and compatible processors except the first-generation 8086 and 8088. In this mode, memory addressing is extended beyond the 1MB limits of the 8088 and real mode and restricted protection levels can be set to trap software crashes and control the system.

protocol

A system of rules and procedures governing communications between two or more devices. Protocols vary, but communicating devices must follow the same protocol to exchange data. The

data format, readiness to receive or send, error detection, and error correction are some of the operations that can be defined in protocols.

proxy server

A computer that acts as a gateway between the computers on a network and the Internet and also provides page caching and optional content filtering and firewall services to the network. Some home network software solutions for Internet sharing, such as WinProxy, use a proxy server.

PS/2 mouse

A mouse designed to plug into a dedicated mouse port (a round, 6-pin DIN connector) on the motherboard, rather than plugging into a serial port. The name comes from the fact that this port was first introduced on the IBM PS/2 systems.

PUN (physical unit number)

A term used to describe a device attached directly to the SCSI bus. Also known as a SCSI ID. As many as eight SCSI devices can be attached to a single SCSI bus, and each must have a unique PUN or ID assigned from 7 to 0. Normally, the SCSI host adapter is assigned the highest-priority ID, which is 7. A bootable hard disk is assigned an ID of 0, and other nonbootable drives are assigned higher priorities.

QAM (quadrature amplitude modulation)

A modulation technique used by high-speed modems that combines both phase and amplitude modulation. This technique enables multiple bits to be encoded in a single time interval.

QDR (quad data rate)

A high-speed SDRAM technology (www.qdrsram.com) that uses separate input and output ports with a DDR interface to enable four pieces of data to be processed at the same time. See also [DDR](#).

QIC (Quarter-Inch Committee)

An industry association that sets hardware and software standards for tape-backup units that use quarter-inchwide tapes. QIC, QIC-Wide, Travan, and Travan NS drives are all based on QIC standards.

Quantum

Formerly a major maker of hard disk drives and now a major maker of attached network storage devices. Quantum-brand disk drives are now sold and supported by Maxtor.

QWERTY keyboard

The standard typewriter or computer keyboard, with the characters Q, W, E, R, T, and Y on the top

row of alpha keys. Because of the haphazard placement of characters, this keyboard can hinder fast typing.

RAID (redundant array of independent or inexpensive disks)

A storage unit that employs two or more drives in combination for fault tolerance and greater performance, used mostly in file server applications. Originally used only with SCSI drives and host adapters, many motherboards now feature ATA/IDE or SATA RAID implementations.

rails

Plastic or metal strips attached to the sides of disk drives mounted in IBM ATs and compatibles so that the drives can slide into place. These rails fit into channels in the side of each disk drive bay position and might be held in position with screws or snap into place.

RAM (random-access memory)

All memory accessible at any instant (randomly) by a microprocessor.

RAM disk

A "phantom disk drive" in which a section of system memory (RAM) is set aside to hold data, just as though it were a number of disk sectors. To an operating system, a RAM disk looks and functions like any other drive.

RAMBUS Dynamic RAM

See [*RDRAM*](#).

RAMDAC (random-access memory digital-to-analog converter)

A special type of DAC found on video cards. RAMDACs use a trio of DACs one each for red, green, and yellow to convert image data into a picture. RAMDACs were formerly separate chips but are now integrated into the 3D accelerator chips on most recent video cards.

random-access file

A file in which all data elements (or records) are of equal length and written in the file end to end, without delimiting characters between. Any element (or record) in the file can be found directly by calculating the record's offset in the file.

random-access memory

See [*RAM*](#).

raster

A pattern of horizontal scanning lines normally on a computer monitor. An electromagnetic field causes the beam of the monitor's tube to illuminate the correct dots to produce the required characters.

raster graphics

A technique for representing a picture image as a matrix of dots. It is the digital counterpart of the analog method used in TV. Several raster graphics standards exist, including PCX, TIFF, BMP, JPEG, and GIF.

RCA jack

Also called a phono connector. A plug and socket for a two-wire coaxial cable used to connect audio and video components. The plug is a 1/8" thick prong that sticks out 5/16" from the middle of a cylinder.

RDRAM (Rambus DRAM)

A high-speed dynamic RAM technology developed by Rambus, Inc., which is supported by Intel's 1999 and later motherboard chipsets. RDRAM transfers data at 1GBps or faster, which is significantly faster than SDRAM and other technologies and which is capable of keeping up with future-generation high-speed processors. Memory modules with RDRAM chips are called RIMMs (Rambus inline memory modules). Rambus licenses its technology to other semiconductor companies, who manufacture the chips and RIMMs. RDRAMs are used by some of Intel's mid-range and high-end chipsets for the Pentium III and Pentium 4 desktop processors and their server counterparts.

read-only file

A file whose attribute setting in the file's directory entry tells DOS not to allow software to write into or over the file.

read-only memory

See [ROM](#).

read/write head

A tiny magnet that reads and writes data on a disk track.

real mode

A mode available in all Intel 8086-compatible processors that enables compatibility with the original 8086. In this mode, memory addressing is limited to 1MB.

real-time

The actual time in which a program or an event takes place. In computing, real-time refers to an operating mode under which data is received and processed and the results returned so quickly that the process appears instantaneous to the user. The term also is used to describe the process of simultaneous digitization and compression of audio and video information.

reboot

The process of restarting a computer and reloading the operating system.

Red Book

More commonly known as Compact Disc-Digital Audio (CD-DA), one of four compact disc standards. Red Book got its name from the color of the manual used to describe the CD-Audio specifications. The Red Book audio standard requires that digital audio be sampled at a 44.1KHz sample rate using 16 bits for each sample. This is the standard used by audio CDs and many CD-ROMs.

redundant power supply (RPS)

A power supply with two or more modules, one of which is in service at a time. If the primary module fails, another automatically takes its place. An RPS might be designed into a server or could be retrofitted later.

refresh cycle

A cycle in which the computer accesses all memory locations stored by DRAM chips so that the information remains intact. DRAM chips must be accessed several times per second; otherwise, the information fades.

refresh rate

Another term for the vertical scan frequency of monitors.

register

Storage area in memory having a specified storage capacity such as a bit, byte, or computer word and intended for a special purpose.

Registry

The system configuration files used by Windows 9x, Windows Me, Windows NT, Windows 2000, and Windows XP to store settings about installed hardware and drivers, user preferences, installed software, and other settings required to keep Windows running properly. Replaces the **WIN.INI** and **SYSTEM.INI** files from Windows 3.x. The Registry structure varies between Windows versions.

remote digital loopback

A test that checks the phone link and a remote modem's transmitter and receiver. Data entered from the keyboard is transmitted from the initiating modem, received by the remote modem's receiver, looped through its transmitter, and returned to the local screen for verification.

remote echo

A copy of the data received by the remote system, returned to the sending system, and displayed onscreen. A function of the remote system.

rendering

Generating a 3D image that incorporates the simulation of lighting effects, such as shadows and reflection.

resolution

1) A reference to the size of the pixels used in graphics. In medium-resolution graphics, pixels are large. In high-resolution graphics, pixels are small. 2) A measure of the number of horizontal and vertical pixels that can be displayed by a video adapter and monitor.

REV

A proprietary hard-diskbased removable-media drive made by Iomega. REV has a native/2.6:1 compressed capacity of 35/90GB per cartridge. REV can be used for backup or primary storage. An autoloader is also available. See also [autoloader](#).

reverse engineering

The act of duplicating a hardware or software component by studying the functions of the component and designing a different one that has the same functions.

RFI (radio frequency interference)

A high-frequency signal radiated by improperly shielded conductors, particularly when signal path lengths are comparable to or longer than the signal wavelengths. The FCC now regulates RFI in computer equipment sold in the U.S. under FCC Regulations, Part 15, Subpart J.

RGB (red green blue)

A type of computer color display output signal comprised of separately controllable red, green, and blue signals; as opposed to composite video, in which signals are combined prior to output. RGB monitors offer much higher resolution and sharper pictures than composite monitors.

ribbon cable

Flat cable with wires running in parallel, such as those used for internal IDE or SCSI.

Rich Text Format (RTF)

A universal file format suitable for exchanging formatted text files between different word processing and page layout programs.

RIMM (Rambus inline memory module)

A type of memory module made using RDRAM chips. See also [RDRAM](#).

RISC (reduced instruction set computer)

Differentiated from CISC, the complex instruction set computer. RISC processors have simple instruction sets requiring only one or a few execution cycles. These simple instructions can be used more effectively than CISC systems with appropriately designed software, resulting in faster operations. See also [CISC](#).

RJ-11

The standard two-wire connector type used for single-line telephone connections.

RJ-14

The standard four-wire connector type used for two-line telephone connections.

RJ-45

A standard connector type used in networking with twisted-pair cabling. Resembles an RJ-11/14 telephone jack, but RJ-45 is larger with more wires.

RLL (run-length limited)

A type of encoding that derives its name from the fact that the techniques used limit the distance (run length) between magnetic flux reversals on the disk platter. Several types of RLL encoding techniques exist, although only two are commonly used. (1,7) RLL encoding increases storage capacity by about 30% over MFM encoding and is most popular in the very highest capacity drives due to a better window margin, whereas (2,7) RLL encoding increases storage capacity by 50% over MFM encoding and is used in the majority of RLL implementations. Most IDE, ESDI, and SCSI hard disks use one of these forms of RLL encoding.

RMA number (return-merchandise authorization number)

A number given to you by a vendor when you arrange to return an item for repairs. Used to track the item and the repair.

ROM (read-only memory)

A type of memory that has values permanently or semipermanently burned in. These locations are used to hold important programs or data that must be available to the computer when the power initially is turned on.

ROM BIOS (read-only memory basic input/output system)

A BIOS encoded in a form of read-only memory for protection.

root directory

The main directory of any hard or floppy disk. It has a fixed size and location for a particular disk volume and can't be resized dynamically the way subdirectories can.

router

A device that is used to connect various networks, intelligently routing information between them. It is used to internetwork similar and dissimilar networks and can select the most expedient route based on traffic load, line speeds, costs, and network failures. Routers use forwarding tables to determine which packets should be forwarded between the connected networks. A cable or DSL modem is an example of a simple router that connects the Internet to your own network. Many routers include firewall capability to block suspect packets from being transmitted between networks.

routine

Set of frequently used instructions. It can be considered as a subdivision of a program with two or more instructions that are related functionally.

RS-232

An interface introduced in August 1969 by the Electronic Industries Association. The RS-232 interface standard provides an electrical description for connecting peripheral devices to computers. Originally, RS-232 (serial) ports on computers used a 25-pin interface, but starting with the IBM AT, most use a 9-pin interface.

RTC (real-time clock)

A battery-powered clock included on the motherboard of 286-class and newer computers. The contents of the RTC are read at startup time to provide the time display in the operating system's clock. It's often part of the NVRAM chip.

S/PDIF (Sony Philips Digital Interface)

Provides digital I/O on high-end sound cards and multimedia-capable video cards. Might use either an RCA jack or optical jack; some devices support both types of S/PDIF connectors.

S-Video (Y/C)

Type of video signal used in the Hi8 and S-VHS videotape formats in which the luminance and chrominance (Y/C) components are kept separate, providing greater control and quality of each image. S-video transmits luminance and color portions separately, thus avoiding the NTSC encoding process and its inevitable loss of picture quality.

SATA (Serial ATA)

A high-speed serial interface designed to replace the current parallel ATA and UltraATA drive interface standards. Serial ATA 1.0 uses a seven-wire data/ground cable and supports direct point-to-point connections to host adapters at initial speeds of up to 150MBps, which is faster than UltraATA-133. SATA 3GB/sec hardware is now available. See also [Ultra DMA](#).

scan codes

The hexadecimal codes actually sent by the keyboard to the motherboard when a key is pressed.

scan lines

The parallel lines across a video screen, along which the scanning spot travels in painting the video information that makes up a monitor picture. NTSC systems use 525 scan lines to a screen; PAL systems use 625.

ScanDisk

The default Windows 9x/Me drive-testing program; might be referred to as error checking in the Drive properties screen. Windows NT, Windows 2000, and Windows XP use CHKDSK to test drives.

scanner

A device that reads an image and converts it into computer data.

scanning frequency

A monitor measurement that specifies how often the image is refreshed. See also [vertical scan frequency](#).

scratch disk

A disk that contains no useful information and can be used as a test disk. IBM has a routine on the Advanced Diagnostics disks that creates a specially formatted scratch disk to be used for testing floppy drives.

SCSI (small computer system interface)

A standard originally developed by Shugart Associates (then called SASI for Shugart Associates System Interface) and later approved by ANSI in 1986. SCSI-2 (now called SPI-2) was approved in 1994, and Ultra3 SCSI (now called SPI-3) was approved in 2000. Ultra4 SCSI (now called SPI-4) was

approved in 2002. 8-bit (narrow) versions of SCSI typically use a 50-pin connector and permit multiple devices (up to 8 including the host) to be connected in daisy-chain fashion. Some low-cost narrow SCSI devices might use a 25-pin connector. Wide and Ultra Wide versions of SCSI use a 68-pin connector and can support up to 16 devices including the host. An 80-pin connector is used on hot-swap SCSI drives used in RAID arrays.

SDLC (Synchronous Data Link Control)

A protocol developed by IBM for software applications and communicating devices operation in IBM's Systems Network Architecture (SNA). Defines operations at the link level of communications for example, the format of data frames exchanged between modems over a phone line.

SDRAM (synchronous DRAM)

RAM that runs at the same speed as the main system bus.

SEC (single edge contact)

An Intel processor packaging design in which the processor and optional L2 cache chips are mounted on a small circuit board (much like an oversized memory SIMM), which might be sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1 or Slot 2, which looks similar to an adapter card slot. Several variations to the SEC cartridge form factor exist: The single edge contact cartridge (SECC) has a cover and a thermal plate; the single edge contact cartridge 2 (SECC2) has a cover, but no thermal plate; and the single edge processor package (SEPP, which is used only with Celeron processors) has no cover or thermal plate. In implementations with no thermal plate, the heatsink is attached directly to the processor package or die.

SECAM

Sequential Couleur A Mémoire (sequential color with memory), the French color TV system also adopted in Russia. The basis of operation is the sequential recording of primary colors in alternate lines. The image format is 4:3, 625 lines, 50Hz, and 6MHz video bandwidth with a total 8MHz of video channel width.

SECC (single edge contact cartridge)

See [SEC](#).

SECC2 (single edge contact cartridge 2)

See [SEC](#).

sector

A section of one track defined with identification markings and an identification number. Most sectors hold 512 bytes of data.

security software

Utility software that uses a system of passwords and other devices to restrict an individual's access to subdirectories and files.

seek time

The amount of time required for a disk drive to move the heads across one-third of the total number of cylinders. Represents the average time it takes to move the heads from one cylinder to another randomly selected cylinder. Seek time is a part of the average access time for a drive.

self-extracting file

An archive file that contains its own extraction program. Open it in a file manager, such as Windows Explorer, to uncompress the files it contains. Because all types of files, including trojans, can be distributed as .exe files (the extension also used by self-extracting files), consider using a program such as WinZip to examine the contents of an .exe file before you open it.

semiconductor

A substance, such as germanium or silicon, whose conductivity is poor at low temperatures but is improved by minute additions of certain substances or by the application of heat, light, or voltage. Depending on the temperature and pressure, a semiconductor can control a flow of electricity. Semiconductors are the basis of modern electronic-circuit technology.

SEPP (single edge processor package)

See [SEC](#).

sequencer

A software program that controls MIDI file messages and keeps track of music timing. Because MIDI files store note instructions instead of actual sounds, a sequencer is needed to play, record, and edit MIDI sounds. Sequencer programs enable recording and playback of MIDI files by storing the instrument, note pitch (frequency), duration (in real-time) that each note is held, and loudness (amplitude) of each musical or sound-effect note.

sequential file

A file in which varying-length data elements are recorded end to end, with delimiting characters placed between each element. To find a particular element, you must read the whole file up to that element.

serial

The transfer of data characters one bit at a time, sequentially, using a single electrical path.

Serial ATA

See [SATA](#).

Serial Attached SCSI (SAS)

A high-speed serial implementation of SCSI adopted in 2003, SAS combines backward compatibility with SATA drives, a current performance of 300MBps, and future improvements to data rates up to 1200MBps.

serial mouse

A mouse designed to connect to a computer's serial port.

serial port

An I/O connector used to connect to serial devices. See also [RS-232](#).

server

A computer in a network that enables resources such as files and printers to be shared by multiple users.

Server System Infrastructure (SSI)

A series of power supply, motherboard, and chassis standards developed by Intel for servers.

ServerWorks

A major developer of server chipsets for use with Pentium III Xeon and Xeon/Xeon MP processors. Now owned by Broadcom.

servo

The mechanism in a drive that enables the head positioner to adjust continuously so that it is precisely placed above a given cylinder in the drive.

servo data

Magnetic markings written on disk platters to guide the read/write heads in drives that use voice-coil actuators.

session (single or multisession)

A term used in CD-ROM recording to describe a recording event. In a single session, data is recorded on a CD-ROM and an index is created. If additional space is left on the disc, another session can be used to record additional files along with another index. Some older CD-ROM drives do not expect additional recording sessions and therefore are incapable of reading the additional session data on the disc. The advent of Kodak's Photo CD propelled the desire for multisession CD-ROM XA (extended architecture) drives.

Session Layer

See [*OSI*](#).

settling time

The time required for read/write heads to stop vibrating after they have been moved to a new track.

shadow mask

A thin screen full of holes that adheres to the inside of a color CRT. The electron beam is aimed through the holes in the mask onto the phosphor dots. See also [*aperture grille*](#).

shadow RAM

A copy of a system's slower-access ROM BIOS placed in faster-access RAM, usually during the startup or boot procedure. This setup enables the system to access BIOS code without the penalty of additional wait states required by the slower ROM chips. Also called shadow ROM or ROM shadowing.

shell

The generic name of any user interface software. **COMMAND.COM** is the standard shell for DOS; 32-bit Windows uses the Windows Explorer as a graphical shell and either **COMMAND.COM** (Windows 9x/Me) or **CMD.EXE** (Windows NT/2000/XP) as the command-line shell.

shielded twisted-pair (STP)

Unshielded twisted-pair (UTP) network cabling with a metal sheath or braid around it to reduce interference, usually used in Token-Ring networks.

shock rating

A rating (usually expressed in G force units) of how much shock a disk drive can sustain without damage. Usually two specifications exist for a drive powered on or off.

signal-to-noise (S/N) ratio

The strength of a video or an audio signal in relation to interference (noise). The higher the S/N ratio, the better the quality of the signal. The latest high-end sound cards have an S/N ratio of

100:1.

silicon

The base material for computer chips. An element, silicon (symbol Si) is contained in the majority of rock and sand on earth and is the second most abundant element on the planet next to oxygen.

SIMD (single instruction multiple data)

The term used to describe the MMX and SSE instructions added to the Intel processors. These instructions can process matrixes consisting of multiple data elements with only a single instruction, enabling more efficient processing of graphics and sound data.

SIMM (single inline memory module)

An array of memory chips on a small PC board with a single row of I/O contacts. SIMMs commonly have 30 or 72 connectors.

single-ended

An electrical signaling method in which a single line is referenced by a ground path common to other signals. In a single-ended bus intended for moderately long distances, commonly one ground line exists between groups of signal lines to provide some resistance to signal crosstalk. Single-ended signals require only one driver or receiver pin per signal, plus one ground pin per group of signals. Single-ended signals are vulnerable to common mode noise and crosstalk but are much less expensive than differential signaling methods.

SIP (single inline package)

A DIP-like package with only one row of leads.

skinny dip

Twenty-four and twenty-eight position DIP devices with .300" row-to-row centerlines.

sleep

See [*suspend*](#).

SLIP (Serial Line Internet Protocol)

An Internet protocol that is used to run the Internet Protocol (IP) over serial lines, such as telephone circuits. IP enables a packet to traverse multiple networks on the way to its final destination. Largely replaced by PPP. See also [*PPP*](#).

slot

A physical connector on a motherboard to hold an expansion card, SIMMs and DIMMs, or a processor card in place and make contact with the electrical connections.

Slot 1

The motherboard connector designed by Intel to accept its SEC cartridge processor design used by the Pentium II and early Celeron and Pentium III processors.

Slot 2

A motherboard connector for Pentium II and Pentium III Xeon processors intended mainly for file server applications. Slot 2 systems support up to four-way symmetric multiprocessing.

SMART (self-monitoring analysis and reporting technology)

An industry standard for advance reporting of imminent hard drive failure. When this feature is enabled in the BIOS and a SMART-compliant hard drive is installed, detected problems can be reported to the computer. This enables the user to replace a drive before it fails. Programs such as Norton System Works and Norton Utilities are compatible with these status messages.

SMBIOS

A BIOS that incorporates system management functions and reporting compatibility with the Desktop Management Interface (DMI).

SMPTE time code

An 80-bit standardized edit time code adopted by SMPTE, the Society of Motion Picture and Television Engineers. The SMPTE time code is a standard used to identify individual video frames in the video-editing process. SMPTE time code controls such functions as play, record, rewind, and forward of video tapes. SMPTE time code displays video in terms of hours, minutes, seconds, and frames for accurate video editing.

snow

A flurry of bright dots that can appear anywhere onscreen on a monitor.

SO-J (small outline J-lead)

A small DIP package with J-shaped leads for surface mounting or socketing.

socket

A receptacle, usually on a motherboard although sometimes also found on expansion cards, into which processors or chips can be plugged.

Socket 18

The Intel specifications for eight different sockets to accept various Intel processors in the 486, Pentium, and Pentium Pro families.

Socket 370

A 370-pin socket used by socketed versions of the Celeron and Pentium III and the VIA C3 processors.

Socket 423

The socket used by the initial versions of the Pentium 4.

Socket 462

See [Socket A](#).

Socket 478

A 478-pin socket used by the Northwood versions of the Pentium 4.

Socket 603

A 603-pin socket used by Intel Xeon processors based on the Pentium 4 design.

Socket 604

A 604-pin socket used by Intel Xeon processors based on the Pentium 4 design. It is backward compatible with Socket 603 processors.

Socket 754

A 754-pin socket used by the AMD Athlon 64 and some versions of the Sempron.

Socket 775

A 775-land socket used by the latest Intel Pentium 4 processors as well as the Pentium 4 Extreme Edition, Pentium D, and Pentium Extreme Edition.

Socket 939

A 939-pin socket used by recent versions of the Athlon 64 FX and all Athlon 64 X2 processors.

Socket 940

A 940-pin socket used by the AMD Opteron processor and early versions of the Athlon 64 FX processor.

Socket A

A 462-pin socket used by socketed versions of the AMD Athlon; all AMD Athlon MP, Athlon XP, Duron; and most versions of the AMD Sempron.

Socket T

Early name for Socket 775. See also [Socket 775](#).

SODIMM (small outline dual inline memory module)

An industry-standard 144-pin memory module designed for use primarily in laptop and portable computers.

soft error

An error in reading or writing data that occurs sporadically, usually because of a transient problem, such as a power fluctuation.

software

A series of instructions loaded in the computer's memory that instructs the computer in how to accomplish a problem or task.

sound card

An adapter card with sound-generating capabilities.

South Bridge

The Intel term for the lower-speed component in the chipset that has always been a single individual chip; it has been replaced in the 8xx-series chipsets by the ICH. The South Bridge connects to the 33MHz PCI bus and contains the IDE interface ports and the interface to the 8MHz ISA bus (when present). It also typically contains the USB interface and even the CMOS RAM and real-time clock functions. The South Bridge contains all the components that make up the ISA bus, including the interrupt and DMA controllers. See also [chipset](#), [ICH](#), [MCH](#), and [North Bridge](#).

SPI (SCSI parallel interface)

Alternative name for common SCSI standards. See also [SCSI](#).

spindle

The central post on which a disk drive's platters are mounted.

spindle count

In notebook and laptop computers with interchangeable drives, spindle count refers to how many drives can be installed and used at the same time.

splitter

Used in DSL and cable modem service to separate Internet signals from those used by the existing telephone (DSL) or cable TV service.

SRAM (static random access memory)

A form of high-speed memory. SRAM chips do not require a refresh cycle like DRAM chips and can be made to operate at very high access speeds. SRAM chips are very expensive because they normally require six transistors per bit. This also makes the chips larger than conventional DRAM chips. SRAM is volatile, meaning it will lose data with no power. SRAMs are often used for cache memory.

SSE (streaming SIMD extensions)

The name given by Intel for the 70 new MMX-type instructions added to the Pentium III processor when it was introduced. See also [MMX](#) and [SIMD](#).

ST-506/412

A hard disk interface invented by Seagate Technology and introduced in 1980 with the ST-506 5MB hard drive. IDE drives emulate this disk interface.

stack

An area of memory storage for temporary values that normally are read in the reverse order from which they are written. Also called last-in, first-out (LIFO).

stackable hub or switch

A hub or switch that can be connected to another hub or switch to increase its capacity. The uplink port on the existing hub or switch is used to connect the new hub or switch.

stair-stepping

Jagged raster representation of diagonals or curves; corrected by antialiasing.

standby

Defines an optional operating state of minimal power reduction with the shortest recovery time.

standby UPS

A UPS that quickly switches into operation during a power outage.

standoffs

In a motherboard and case design, small nonconductive spacers (usually plastic or nylon) used to keep the underside of the motherboard from contacting the metallic case, therefore preventing short circuits of the motherboard.

start/stop bits

The signaling bits attached to a character before and after the character is transmitted during asynchronous transmission.

starting cluster

The number of the first cluster occupied by a file. Listed in the directory entry of every file.

stepper motor actuator

An assembly that moves disk drive read/write heads across platters by a sequence of small partial turns of a stepper motor. Once common on low-cost hard disk drives of 40MB or less, stepper motor actuators are now confined to floppy disk drives.

stepping

The code used to identify the revision of a processor. New masks are introduced to build each successive stepping, incorporating any changes necessary to fix known bugs in prior steppings.

storage

Device or medium on or in which data can be entered or held and retrieved at a later time. Synonymous with memory.

streaming

In tape backup, a condition in which data is transferred from the hard disk as quickly as the tape drive can record the data so the drive does not start and stop or waste tape.

string

A sequence of characters.

subdirectory

A directory listed in another directory. Subdirectories themselves exist as files.

subroutine

A segment of a program that can be executed by a single call. Also called program module.

Super DLT (SDLT)

An enhanced version of the DLT tape standard that supports faster data transfer and native/2:1 compressed capacities up to 300/600GB.

superscalar execution

The capability of a processor to execute more than one instruction at a time.

surface mount

Chip carriers and sockets designed to mount to the surface of a PC board.

surge protector

A device in the power line that feeds the computer and provides protection against voltage spikes and other transients.

suspend

Refers to a level of power management in which substantial power reduction is achieved by the display or other components. The components can have a longer recovery time from this state than from the standby state.

SVGA (Super VGA)

Refers to a video adapter or monitor capable of 800x600 resolution.

SWEDAC (Swedish Board for Technical Accreditation)

Regulatory agency establishing standards such as MPR1 and MPR2, which specify maximum values for both alternating electric fields and magnetic fields and provide monitor manufacturers with guidelines in creating low-emission monitors.

switch

Also called a switching hub, it's a type of hub that reads the destination address of each packet and then forwards the packet to only the correct port, minimizing traffic on other parts of the network. Unlike a regular hub, which wastes network bandwidth by copying packets to all ports, a switch forwards packets to only their intended recipients, immediately reducing network traffic jams and improving overall efficiency for the entire network. Many switches also support full-duplex service, effectively doubling the speed of full-duplex network cards attached to the switch. See also [hub](#).

SXGA (Super XGA)

Refers to a video adapter or monitor capable of 1280x1024 or greater resolution.

synchronous communication

A form of communication in which blocks of data are sent at strictly timed intervals. Because the timing is uniform, no start or stop bits are required. Compare with asynchronous communication. Some mainframes support only synchronous communication unless a synchronous adapter and appropriate software have been installed. See also [asynchronous communication](#).

system crash

A situation in which the computer freezes up and refuses to proceed without rebooting. Usually caused by faulty software, it's unlike a hard disk crash no permanent physical damage occurs.

system files

Files with the system attribute. Usually, the hidden files that are used to boot the operating system. The MS-DOS and Windows 9x system files include **IO.SYS** and **MSDOS.SYS**; the IBM DOS system files are **IBMBIO.COM** and **IBMDOS.COM**.

System Management Mode (SMM)

Circuitry integrated into Intel processors that operates independently to control the processor's power use based on its activity level. It enables the user to specify time intervals after which the CPU will be powered down partially or fully and also supports the suspend/resume feature that enables instant power-on and power-off.

tape drive

Any data storage drive that uses tape as the storage medium.

tape library

An array of tape drives that can be partitioned into multiple logical libraries. Tape libraries incorporate autoloaders. See also [autoloader](#).

target

A device attached to a SCSI bus that receives and processes commands sent from another device (the initiator) on the SCSI bus. A SCSI hard disk is an example of a target.

T13

The T13 Technical Committee (www.t13.org) is responsible for developing ATA and SATA standards.

TCM (Trellis-coded modulation)

An error-detection and correction technique employed by high-speed modems to enable higher-speed transmissions that are more resistant to line impairments.

TCO

1) Refers to the Swedish Confederation of Professional Employees, which has set stringent standards for devices that emit radiation. See also [MPR](#). 2) Total cost of ownership. The cost of using a computer. It includes the cost of the hardware, software, and upgrades as well as the cost of the in-house staff and consultants who provide training and technical support.

TCP (tape carrier package)

A method of packaging processors for use in portable systems that reduces the size, power consumed, and heat generated by the chip. A processor in the TCP form factor is essentially a raw die encased in an oversized piece of polyamide film. The film is laminated with copper foil that is etched to form the leads that will connect the processor to the motherboard.

TCP port number

Logical port numbers used by TCP to communicate between computers for example, web browsing (<http://>) uses TCP port 80. POP3 email uses TCP port 110. Some firewalls require you to manually configure open TCP port numbers to allow certain processes and programs to work.

TCP/IP (Transmission Control Protocol/Internet Protocol)

A set of protocols developed by the U.S. Department of Defense (DoD) to link dissimilar computers across many types of networks. This is the primary protocol used by the Internet.

TEB

Thin Electronics Bay is an SSI-developed standard for rack-mounted servers.

temporary backup

A second copy of a work file, usually having the extension BAK. Created by application software so you easily can return to a previous version of your work.

temporary file

A file temporarily (and usually invisibly) created by a program for its own use.

tera

A multiplier indicating one trillion (1,000,000,000,000) of some unit. Abbreviated as t or T. A binary tera (now called a tebi) is 1,099,511,627,776.

terabyte (T)

A unit of information storage equal to 1,000,000,000 bytes.

terminal

A device whose keyboard and display are used for sending and receiving data over a communications link. Differs from a microcomputer in that it has no internal processing capabilities. Used to enter data into or retrieve processed data from a system or network.

terminal mode

An operational mode required for microcomputers to transmit data. In terminal mode, the computer acts as though it were a standard terminal, such as a teletypewriter, rather than a data processor. Keyboard entries go directly to the modem, whether the entry is a modem command or data to be transmitted over the phone lines. Received data is output directly to the screen. The more popular communications software products control terminal mode and enable more complex operations, including file transmission and saving received files.

terminator

Hardware or circuits that must be attached to or enabled at both ends of an electrical bus. Functions to prevent the reflection or echoing of signals that reach the ends of the bus and to ensure that the correct impedance load is placed on the driver circuits on the bus. Most commonly used with the SCSI bus and Thin Ethernet.

TFT (thin film transistor)

The highest quality and brightest LCD color display type. A method for packaging one-four transistors per pixel within a flexible material that is the same size and shape as the LCD display, which enables the transistors for each pixel to lie directly behind the liquid crystal cells they control.

thick Ethernet

See [10BASE-5](#).

thin Ethernet

See [10BASE-2](#).

thin-film media

Hard disk platters that have a thin film (usually three-millionths of an inch) of medium deposited on the aluminum substrate through a sputtering or plating process.

Thinnet

See [10BASE-2](#).

through-hole

Chip carriers and sockets equipped with leads that extend through holes in a PC board.

throughput

The amount of user data transmitted per second without the overhead of protocol information, such as start and stop bits or frame headers and trailers.

thumb drive

See [keychain drive](#).

TIFF (tagged image file format)

A way of storing and exchanging digital image data. Developed by Aldus Corporation, Microsoft Corporation, and major scanner vendors to help link scanned images with the popular desktop publishing applications. Supports three main types of image data: black-and-white data, halftones or dithered data, and grayscale data. Compressed TIFF files are stored using lossless compression.

time code

A frame-by-frame address code time reference recorded on the spare track of a videotape or inserted in the vertical blanking interval. The time code is an eight-digit number encoding time in hours, minutes, seconds, and video frames.

Token-Ring

A type of local area network in which the workstations relay a packet of data called a token in a logical ring configuration. When a station wants to transmit, it takes possession of the token, attaches its data, and then frees the token after the data has made a complete circuit of the

electrical ring. Transmits at speeds of 16Mbps. Because of the token-passing scheme, access to the network is controlled, unlike the slower 10BASE-X Ethernet system in which collisions of data can occur, which wastes time. The Token-Ring network uses shielded twisted-pair wiring, which is cheaper than the coaxial cable used by 10BASE-2 and 10BASE-5 Ethernet and ARCnet.

toner

The ultrafine, colored, plastic powder used in laser printers, LED printers, and photocopiers to produce the image on paper.

tower

A personal computer that normally sits on the floor and is mounted vertically rather than horizontally.

TPI (tracks per inch)

Used as a measurement of magnetic track density. Standard 5 1/4" 360KB floppy disks have a density of 48TPI, and the 1.2MB disks have a 96TPI density. All 3 1/2" disks have a 135.4667TPI density, and hard disks can have densities greater than 3,000TPI.

track

One of the many concentric circles that holds data on a disk surface. Consists of a single line of magnetic flux changes and is divided into some number of 512-byte sectors.

track density

Expressed as tracks per inch (TPI); defines how many tracks are recorded in 1" of space measured radially from the center of the disk. Sometimes also called radial density.

track-to-track seek time

The time required for read/write heads to move between adjacent tracks.

transistor

A semiconductor device invented in 1947 at Bell Labs (released in 1948) that is used to amplify a signal or open and close a circuit. In digital computers, it functions as an electronic switch. It is reduced to microscopic size in modern digital integrated circuits containing 100 million or more individual transistors.

Transport Layer

In the OSI reference model, when more than one packet is in process at any time, such as when a large file must be split into multiple packets for transmission, this is the layer that controls the sequencing of the message components and regulates inbound traffic flow. See also [OSI](#).

transportable computer

A computer system larger than a portable system and similar in size and shape to a portable sewing machine. Most transportables conform to a design similar to the original Compaq portable, with a built-in CRT display. These systems are characteristically very heavy and run on only AC power. Because of advances primarily in LCD and plasma-display technology, these systems are obsolete and have been replaced by portable systems.

troubleshooting

The task of determining the cause of a problem.

true-color images

Also called 24-bit color images because each pixel is represented by 24 bits of data, allowing for 16.7 million colors. The number of colors possible is based on the number of bits used to represent the color. If 8 bits are used, 256 possible color values (2^8) exist. To obtain 16.7 million colors, each of the primary colors (red, green, and blue) is represented by 8 bits per pixel, which enables 256 possible shades for each of the primary red, green, and blue colors or $256 \times 256 \times 256 = 16.7$ million total colors.

TrueType

An Apple/Microsoft-developed scalable font technology designed to provide a high-performance alternative to PostScript Type 1 fonts. TrueType fonts are supported by both Windows and MacOS, but a particular TrueType font must either be made in both MacOS and Windows versions or support the cross-platform OpenType font format to be used on both platforms.

TSR (terminate-and-stay-resident)

A program that remains in memory after being loaded. Because they remain in memory, TSR programs can be reactivated by a predefined keystroke sequence or other operation while another program is active. Usually called resident programs. TSR programs are often loaded from the **AUTOEXEC. BAT** file used at startup by DOS and Windows 9x.

TTL (transistor-to-transistor logic)

Digital signals often are called TTL signals. A TTL display is a monitor that accepts digital input at standardized signal voltage levels.

TWAIN

Imaging standard used to interface scanners and digital cameras to applications such as Photoshop and other image editors. TWAIN enables the user to scan or download pictures without exiting the image-editing program.

TweakUI

An unsupported software utility provided by Microsoft for 32-bit Windows users. TweakUI allows users to change the user interface and adjust Registry settings without manual Registry editing.

twisted pair

A type of wire in which two small, insulated copper wires are wrapped or twisted around each other to minimize interference from other wires in the cable. Two types of twisted-pair cables are available: unshielded and shielded. Unshielded twisted-pair (UTP) wiring commonly is used in telephone cables and 10BASE-T, 100BASE-TX, and 1000BASE-T networking and provides little protection against interference. Shielded twisted-pair (STP) wiring is used in some networks or any application in which immunity from electrical interference is more important. Twisted-pair wire is much easier to work with than coaxial cable and is cheaper as well.

two-way server

A server with two separate processors. A server running a dual-core processor offers performance close to, but not quite matching, the performance of a two-way server.

typematic

The keyboard repeatedly sending the keypress code to the motherboard for a key that is held down. The delay before the code begins to repeat and the speed at which it repeats are user adjustable through **MODE** commands in DOS or the Windows Control Panel.

UART (Universal Asynchronous Receiver Transmitter)

A chip device that controls the RS-232 serial port in a PC-compatible system. Originally developed by National Semiconductor, several UART versions are in PC-compatible systems: The 8250B is used in PC- and XT-class systems, and the 16450 and 16550 series are used in AT-class systems. The 16650 and higher UARTs are used for specialized high-speed serial communication cards.

UDF (Universal Disk Format)

The disk format used by packet-writing software, such as Adaptec DirectCD. See also [Mt. Rainier](#) and [packet writing](#).

Ultra DMA (UDMA or Ultra ATA)

A protocol for transferring data to an ATA interface hard drive. The Ultra DMA/33 protocol transfers data in burst mode at a rate of 33MBps, whereas the even faster Ultra DMA/66 protocol transfers at 66MBps. Ultra DMA/66 also requires the use of a special 80-conductor cable for signal integrity. This cable also is recommended for Ultra DMA/33 and is backward compatible with standard ATA/IDE cables. The fastest UDMA modes are Ultra DMA/100 (supported by most recent chipsets) and Ultra DMA/133 (introduced by Maxtor in 2001).

UltraXGA (UXGA)

A screen resolution of 1,600x1,200.

Ultrium

The high-capacity implementation of the Linear Tape Open (LTO) standard. LTO-3 Ultrium is the highest-capacity version currently available, with native/2:1 compressed capacity of 400/800GB.

UMB (upper memory block)

A block of unused memory in the upper memory area (UMA), which is the 384KB region between 640KB and 1MB of memory space in the PC. BIOS chips and memory buffers on add-on cards must be configured to use empty areas of the UMB; otherwise, they will not work.

unformatted capacity

The total number of bytes of data that can fit on a disk. The formatted capacity is lower because space is lost defining the boundaries between sectors. For example, some vendors have referred to the high-density 1.44MB floppy disk as a 2.0MB disk (2.0MB is the unformatted capacity). However, because most media is preformatted today, this issue is fading away.

Unicode

A worldwide standard for displaying, interchanging, and processing all types of language texts, including both those based on letters (such as Western European languages) and pictographs (such as Chinese, Japanese, and Korean).

uninterruptible power supply (UPS)

A device that supplies power to the computer from batteries so power will not stop, even momentarily, during a power outage. The batteries are recharged constantly from a wall socket.

Universal Asynchronous Receiver Transmitter

See [UART](#).

unzipping

The process of extracting one or more files from a PKZIP or WinZip-compatible archive file.

UPC (universal product code)

A 10-digit computer-readable bar code used in labeling retail products. The code in the form of vertical bars includes a five-digit manufacturer identification number and a five-digit product code number.

update

To modify information already contained in a file or program with current information.

upper memory area (UMA)

The 384KB of memory between 640KB and 1MB. See also [UMB](#).

URL (uniform resource locator)

The primary naming scheme used to identify a particular site or file on the World Wide Web. URLs combine information about the protocol being used, the address of the site where the resource is located, the subdirectory location at the site, and the name of the particular file (or page) in question.

USB (universal serial bus)

USB version 1.1 is a 12Mbps (1.5MBps) interface over a simple four-wire connection. The bus supports up to 127 devices and uses a tiered star topology built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes. USB 2.0, also called High-Speed USB, runs at 480Mbps and handles multiple devices better than USB 1.1.

utility

A program that carries out routine procedures to make computer use easier.

UTP (unshielded twisted pair)

A type of wire often used indoors to connect telephones or computer devices. Comes with two or four wires twisted inside a flexible plastic sheath or conduit and uses modular plugs and phone jacks.

V.21

An ITU standard for modem communications at 300bps. Modems made in the U.S. or Canada follow the Bell 103 standard but can be set to answer V.21 calls from overseas. The actual transmission rate is 300 baud and employs frequency shift keying (FSK) modulation, which encodes a single bit per baud.

V.22

An ITU standard for modem communications at 1,200bps, with an optional fallback to 600bps. V.22 is partially compatible with the Bell 212A standard observed in the U.S. and Canada. The actual transmission rate is 600 baud, using differential-phase shift keying (DPSK) to encode as much as 2 bits per baud.

V.22bis

An ITU standard for modem communications at 2,400bps. Includes an automatic link-negotiation fallback to 1,200bps and compatibility with Bell 212A/V.22 modems. The actual transmission rate is 600 baud, using quadrature amplitude modulation (QAM) to encode as much as 4 bits per baud.

V.23

An ITU standard for modem communications at 1,200bps or 600bps with a 75bps back channel. Used in the United Kingdom for some videotext systems.

V.25

An ITU standard for modem communications that specifies an answer tone different from the Bell answer tone used in the U.S. and Canada. Most intelligent modems can be set with an ATB0 command so they use the V.25 2,100Hz tone when answering overseas calls.

V.32

An ITU standard for modem communications at 9,600bps and 4,800bps. V.32 modems fall back to 4,800bps when line quality is impaired and fall forward again to 9,600bps when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and optional trellis-coded modulation (TCM) to encode as much as 4 data bits per baud.

V.32bis

An ITU standard that extends the standard V.32 connection range and supports 4,800bps; 7,200bps; 9,600bps; 12,000bps; and 14,400bps transmission rates. V.32bis modems fall back to the next lower speed when line quality is impaired, fall back further as necessary, and fall forward to the next higher speed when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and trellis-coded modulation (TCM) to encode as much as 6 data bits per baud.

V.32terbo

A proprietary standard proposed by several modem manufacturers that will be cheaper to implement than the standard V.32 fast protocol but that will support transmission speeds of up to only 18,800bps. Because it is not an industry standard, it is not likely to have widespread industry support.

V.34

An ITU standard that extends the standard V.32bis connection range, supporting 28,800bps transmission rates as well as all the functions and rates of V.32bis. This was called V.32fast or V. fast while under development.

V.34+

An ITU standard that extends the standard V.34 connection range, supporting 33,600bps transmission rates as well as all the functions and rates of V.34.

V.42

An ITU standard for modem communications that defines a two-stage process of detection and negotiation for LAPM error control. Also supports MNP error-control protocol, Levels 14.

V.42bis

An extension of CCITT V.42 that defines a specific data-compression scheme for use with V.42 and MNP error control.

V.44

ITU-T designation for a faster data-compression scheme than V.42bis. V.44 can compress data up to 6:1. V.44 is included on most V.92-compliant modems. See also [V.92](#).

V.90

ITU-T designation for defining the standard for 56Kbps communication. Supersedes the proprietary X2 schemes from U.S. Robotics (3Com) and K56flex from Rockwell.

V.92

ITU-T designation for an improved version of the V.90 protocol. V.92 allows faster uploading (up to 48Kbps), faster connections, and optional modem-on-hold (enabling you to take calls while online). Most V.92 modems also support V.44 compression. See also [V.44](#).

V-Link

A VIA Technologies high-speed (266MBps) bus between the North Bridge and South Bridge chips in VIA chipsets, such as the P4X266 (for Pentium 4) and KT266/266A (for Athlon/Duron). V-Link is twice as fast as the PCI bus and provides a dedicated pathway for data transfer.

vaccine

A type of program used to locate and eradicate virus code from infected programs or systems.

vacuum tube

A device used to amplify or control electronic signals, it contains two major components: a cathode (a filament used to generate electrons) and an anode (a plate that captures electron current after it flows through one or more grids). Largely replaced by the transistor and integrated circuit in most small electronics applications, vacuum tubes in the form of CRTs are still used to make conventional monitors. The Aopen AX4B-533 Tube motherboard uses vacuum tubes for higher-quality integrated sound. See also [CRT](#).

VCPI (virtual control program interface)

A 386 and later processor memory management standard created by Phar Lap software in conjunction with other software developers. VCPI provides an interface between applications using DOS extenders and 386 memory managers.

vertex

The corner of a triangle in 3D graphics. The plural of vertex is vertices. See also [vertex shader](#).

vertex shader

A graphics processing function built in to recent 3D graphics chips that manipulates vertices by adding color, shading, and texture effects. Recent GPUs such as the NVIDIA GeForce 3 and GeForce Ti and the ATI Radeon series incorporate vertex shaders. See also [GPU](#), [hardware shader](#), and [pixel shader](#).

vertical blanking interval (VBI)

The top and bottom lines in the video field, in which frame numbers, picture stops, chapter stops, white flags, closed captions, and more can be encoded. These lines do not appear on the display screen but maintain image stability and enhance image access.

vertical scan frequency

The rate at which the electron gun in a monitor scans or refreshes the entire screen each second.

very large scale integration

See [IC](#).

VESA (Video Electronics Standards Association)

Founded in the late 1980s by NEC Home Electronics and eight other leading video board manufacturers with the main goal to standardize the electrical, timing, and programming issues surrounding 800x600 resolution video displays, commonly known as Super VGA. VESA has also developed the Video Local Bus (VL-Bus) standard for connecting high-speed adapters directly to the local processor bus. The most recent VESA standards involve digital flat-panel displays and display identification.

VFAT (virtual file allocation table)

A file system used in Windows for Workgroups and Windows 9x. VFAT provides 32-bit protected mode access for file manipulation and supports long filenames (LFNs) up to 255 characters in Windows 95 and later. VFAT can also read disks prepared with the standard DOS 16-bit FAT. VFAT was called 32-bit file access in Windows for Workgroups. VFAT is not the same as FAT32.

VGA (video graphics array)

A type of PC video display circuit (and adapter) first introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80x25 characters in 16 colors with a character box of 9x16 pixels. Graphics are supported at a maximum resolution of 320x200 pixels in 256 (from a palette of 262,144) colors or 640x480 pixels in 16 colors. The VGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz and supports analog color or analog monochrome displays. Also refers generically to any adapter or display capable of 640x480 resolution.

VHS (Video Home System)

A popular consumer videotape format developed by Matsushita and JVC.

VIA Technologies

A popular vendor of chipsets for AMD Athlon and Intel Pentium 4based systems; it's also the maker of the VIA C3 processor.

video

A system of recording and transmitting primarily visual information by translating moving or still images into electrical signals. The term *video* properly refers to only the picture, but as a generic term, *video* usually embraces audio and other signals that are part of a complete program. Video now includes not only broadcast television but many nonbroadcast applications, such as corporate communications, marketing, home entertainment, games, teletext, security, and even the visual display units of computer-based technology.

Video 8 or 8mm Video

Video format based on the 8mm videotapes popularized by Sony for camcorders.

video adapter

An expansion card or chipset built into a motherboard that provides the capability to display text and graphics onscreen. If the adapter is part of an expansion card, it also includes the physical connector for the monitor cable. If the chipset is on the motherboard, the video connector is on the motherboard as well.

video graphics array

See [VGA](#).

video-on-CD or video CD

A full-motion digital video format using MPEG video compression and incorporating a variety of VCR-like control capabilities. See also [White Book](#).

virtual disk

A RAM disk or "phantom disk drive" in which a section of system memory (usually RAM) is set aside to hold data, just as though it were several disk sectors. To DOS, a virtual disk looks and functions like any other "real" drive.

virtual IRQ

PCI IRQs higher than 15 (the end of the standard IRQ listing). Windows XP Service Pack 1 and later and Windows 2003 Server assign PCI devices that share hardware IRQs virtual IRQ numbers in Device Manager. See also [IRQ](#).

virtual memory

A technique by which operating systems such as 32-bit Windows versions load more programs and data into memory than they can hold. Parts of the programs and data are kept on disk and constantly swapped back and forth into system memory. The applications' software programs are unaware of this setup and act as though a large amount of memory is available.

virtual real mode

A mode available in all Intel 80386-compatible processors. In this mode, memory addressing is limited to 4,096MB, restricted protection levels can be set to trap software crashes and control the system, and individual real-mode compatible sessions can be set up and maintained separately from one another.

virtual tape library

A disk-based backup device that emulates a tape library. See also [tape library](#).

virus

A type of resident program designed to replicate itself. Usually at some later time when the virus is running, it causes an undesirable action to take place.

VL-Bus (VESA Local Bus)

A standard 32-bit expansion slot bus specification used in 486 PCs, the VL-Bus connector was an extension of the ISA slot; any VL-Bus slot is also an ISA slot. Replaced by the PCI bus, the VL-Bus slot was used on only a very few early Pentium systems.

VMM (Virtual Memory Manager)

A facility in Windows enhanced mode that manages the task of swapping data in and out of 386 and later processor virtual real-mode memory space for multiple non-Windows applications running in virtual real mode.

vmstat

A command-line Linux program that can be used to view server performance and look for bottlenecks.

voice-coil actuator

A device that moves read/write heads across hard disk platters by magnetic interaction between coils of wire and a magnet. Functions somewhat like an audio speaker, from which the name originated. The standard actuator type on hard drives.

volatile memory

Memory that does not hold data without power. Both Dynamic RAM (the main RAM in a computer) and Static RAM (used for cache memory) are considered volatile memory. See also [*nonvolatile memory*](#).

voltage reduction technology

An Intel processor technology that enables a processor to draw the standard voltage from the motherboard but run the internal processor core at a lower voltage.

voltage regulator

A device that smoothes out voltage irregularities in the power fed to the computer.

volume

A portion of a disk signified by a single drive specifier. Under DOS v3.3 and later, a single hard disk can be partitioned into several volumes, each with its own logical drive specifier (C:, D:, E:, and so on).

volume label

An identifier or name of up to 11 characters that names a disk.

VPN (virtual private network)

A private network operated within a public network. To maintain privacy, VPNs use access control and encryption.

VRAM (video random-access memory)

VRAM chips are modified DRAMs on video boards that enable simultaneous access by the host system's processor and the processor on the video board. A large amount of information therefore

can be transferred quickly between the video board and system processor. Sometimes also called dual-ported RAM. It has been replaced by SDRAM, SGRAM, and DDR SDRAM on recent high-performance video cards.

VxD (virtual device driver)

A special type of Windows driver. VxDs run at the most privileged CPU mode (ring 0) and enable low-level interaction with the hardware and internal Windows functions.

W3C (World Wide Web Consortium)

Sets standards for HTML, XML, and the Web.

wafer

A thin, circular piece of silicon either 8" (200mm) or 12" (300mm) in diameter from which processors, memory, and other semiconductor electronics are manufactured.

wait states

One or more pause cycles added during certain system operations that require the processor to wait until memory or some other system component can respond. Adding wait states enables a high-speed processor to synchronize with lower-cost, slower components. A system that runs with "zero wait states" requires none of these cycles because of the use of faster memory or other components in the system. The widespread use of L1 and L2 memory caches has made the issue of wait states largely irrelevant. See also [L1 cache](#) and [L2 cache](#).

warm boot

Rebooting a system by means of a software command rather than turning the power off and back on. See also [cold boot](#).

wave table synthesis

A method of creating synthetic sound on a sound card that uses actual musical instrument sounds sampled and stored on ROM (or RAM) on the sound card or in system RAM. The sound card then modifies this sample to create any note necessary for that instrument. Produces much better sound quality than FM synthesis.

webcam

An inexpensive (usually under \$100) video camera that plugs into a USB or an IEEE 1394/FireWire port for use with video chat, websites, or email programs.

Whetstone

A benchmark program developed in 1976 and designed to simulate arithmetic-intensive programs

used in scientific computing. Remains completely CPU-bound and performs no I/O or system calls. Originally written in ALGOL, although the C and Pascal versions became more popular by the late 1980s. The speed at which a system performs floating-point operations often is measured in units of Whetstones.

White Book

A standard specification developed by Philips and JVC in 1993 for storing MPEG standard video on CDs. An extension of the Red Book standard for digital audio, Yellow Book standard for CD-ROM, Green Book standard for CD-I, and Orange Book standard for CD write-once.

Whitney technology

A term referring to a magnetic disk design that usually has oxide or thin film media, thin film read/write heads, low floating-height sliders, and low-mass actuator arms that together allow higher bit densities than the older Winchester technology. Whitney technology first was introduced with the IBM 3370 disk drive, circa 1979.

Wi-Fi

Name for IEEE 802.11compliant network hardware that also meets the interoperability standards of the Wireless Ethernet Compatibility Alliance (WECA). Despite the presence of Wi-Fi approval for various brands of hardware, achieving the simplest setup and operation is still easier if you purchase Wi-Fi wireless NICs and access points that support the same standard (802.11a, b, or g) from the same vendor. See also [802.11](#).

wide area network (WAN)

A LAN that extends beyond the boundaries of a single building.

Winchester drive

Any ordinary, nonremovable (or fixed) hard disk drive. The name originates from a particular IBM drive in the 1960s that had 30MB of fixed and 30MB of removable storage. This 30-30 drive matched the caliber figure for a popular series of rifles made by Winchester, so the slang term *Winchester* was applied to any fixed-platter hard disk.

Winchester technology

The term *Winchester* is loosely applied to mean any disk with a fixed or nonremovable recording medium. More precisely, the term applies to a ferrite read/write head and slider design with oxide media that was first employed in the IBM 3340 disk drive, circa 1973. Virtually all drives today actually use developments of Whitney technology.

Wintel

The common name given to computers running Microsoft Windows using Intel (or compatible) processors. A slang term for the PC standard.

wire frames

The most common technique used to construct a 3D object for animation. A wire frame is given coordinates of length, height, and width. Wire frames are then filled with textures, colors, and movement. Transforming a wire frame into a textured object is called rendering.

word length

The number of bits in a data character without parity, start, or stop bits.

workstation

1) A somewhat vague term describing any high-performance, single-user computer that usually has been adapted for specialized graphics, computer-aided design, computer-aided engineering, or scientific applications. 2) A computer connected to a server.

World Wide Web (WWW)

Also called the Web. A graphical information system based on hypertext that enables a user to easily access documents located on the Internet.

WORM (write-once, read-many or multiple)

An optical mass-storage device capable of storing many megabytes of information but that can be written to only once on any given area of the disk. A WORM disk typically holds more than 200MB of data. Because a WORM drive can't write over an old version of a file, new copies of files are made and stored on other parts of the disk whenever a file is revised. WORM disks are used to store information when a history of older versions must be maintained. Recording on a WORM disk is performed by a laser writer that burns pits in a thin metallic film (usually tellurium) embedded in the disk. This burning process is called ablation. WORM drives are frequently used for archiving data. WORM drives have been replaced by CD-R drives, which have a capacity of 650MB700MB but have similar characteristics.

write precompensation

A modification applied to write data by a controller to partially alleviate the problem of bit shift, which causes adjacent 1s written on magnetic media to read as though they were farther apart. When adjacent 1s are sensed by the controller, precompensation is used to write them more closely together on the disk, thus enabling them to be read in the proper bit cell window. Drives with built-in controllers typically handle precompensation automatically. Precompensation usually is required for the inner cylinders of now-obsolete oxide media drives.

write protect

Preventing a removable disk or Sony Memory Stick from being overwritten by means of covering a notch or repositioning a sliding switch, depending on the type of media.

X2

A proprietary modem standard developed by U.S. Robotics (since acquired by 3Com) that enables modems to receive data at up to 56Kbps. This has been superseded by the V.90 standard. See also [V.90](#) and [V.92](#).

x86

A generic term referring to Intel and Intel-compatible PC microprocessors. Although the Pentium family processors do not have a numeric designation because of trademark law limitations on trademarking numbers, they are later generations of this family.

Xeon

Intel's family name for its server processors derived from the Pentium II, Pentium III, and Pentium 4 desktop processors. The Pentium II Xeon and Pentium III Xeon use Slot 2, whereas Xeon (the Pentium 4 version does not have a numerical designation) uses the Socket 603 or Socket 604. All Xeon processors have larger caches and memory addressing schemes than their desktop counterparts. Some Xeon processors support EM64T 64-bit extensions, and a dual-core version of Xeon with EM64T support was introduced in the first quarter of 2006.

Xeon MP

A version of the Intel Xeon made especially for four-way and larger server implementations. Some versions of the Xeon MP support EM64T 64-bit extensions, and a dual-core version with EM64T support was introduced in the first quarter of 2006.

XGA (extended graphics array)

A type of PC video display circuit (and adapter) first introduced by IBM on October 30, 1990, that supports text and graphics. Text is supported at a maximum resolution of 132x60 characters in 16 colors with a character box of 8x6 pixels. Graphics are supported at a maximum resolution of 1024x768 pixels in 256 (from a palette of 262,144) colors or 640x480 pixels in 65,536 colors. The XGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz or 35.52KHz and supports analog color or analog monochrome displays. Also used to refer generically to any adapter or display capable of 1024x768 resolution.

XML (Extensible Markup Language)

A standard for creating and sharing data and data formats over the Internet and other networks. XML, like HTML, uses markup tags to control the page, but XML tags control both appearance and the uses of the data and can be extended with new tags created by any XML user. See also [W3C](#).

XMM (extended memory manager)

A driver that controls access to extended memory on 286 and later processor systems. HIMEM.SYS is an example of an XMM that comes with DOS and Windows 9x.

XModem

A file-transfer protocol with error checking developed by Ward Christensen in the mid-1970s and placed in the public domain. Designed to transfer files between machines running the CP/M operating system and using 300bps or 1,200bps modems. Until the late 1980s, because of its simplicity and public-domain status, XModem remained the most widely used microcomputer file-transfer protocol. In standard XModem, the transmitted blocks are 128 bytes. 1KB-XModem is an extension to XModem that increases the block size to 1,024 bytes. Many newer file-transfer protocols that are much faster and more accurate than XModem have been developed, such as YModem and ZModem.

XMS (extended memory specification)

A Microsoft-developed standard that provides a way for real-mode applications to access extended memory in a controlled fashion. The XMS standard is available from Microsoft.

XON/XOFF

Standard ASCII control characters used to tell an intelligent device to stop or resume transmitting data. In most systems, pressing Ctrl+S sends the XOFF character. Most devices understand Ctrl+Q as XON; others interpret the pressing of any key after Ctrl+S as XON.

Y-connector

A Y-shaped splitter cable that divides a source input into two output signals.

Y-mouse

A family of adapters from P.I. Engineering that enables a single mouse port to drive two devices. P. I. Engineering also makes the Y-see adapter for dual monitors and the Y-key adapter for dual keyboards.

Yellow Book

The standard used by CD-ROM. Multimedia applications most commonly use the Yellow Book standard, which specifies how digital information is to be stored on the CD-ROM and read by a computer. Extended architecture (XA) is currently an extension of the Yellow Book that enables the combination of various data types (audio and video, for example) onto one track in a CD-ROM. Without XA, a CD-ROM can access only one data type at a time. Many CD-ROM drives are now XA capable.

Yellow Book standards

See [CD-ROM](#).

YModem

A file-transfer protocol first released as part of Chuck Forsberg's YAM (yet another modem) program. An extension to XModem designed to overcome some of the limitations of the original. Enables information about the transmitted file, such as the filename and length, to be sent along with the file data and increases the size of a block from 128 bytes to 1,024 bytes. YModem-batch adds the capability to transmit batches, or groups, of files without operator interruption. YModemG is a variation that sends the entire file before waiting for an acknowledgment. If the receiving side detects an error midstream, the transfer is aborted. YModemG is designed for use with modems that have built-in error-correcting capabilities.

Z-buffering

A 3D graphics technique used to determine which objects in a 3D scene will be visible to the user and which will be blocked by other objects. Z-buffering displays only the visible pixels in each object.

zero wait states

See [wait states](#).

ZIF (zero insertion force)

Sockets that require no force for the insertion of a chip carrier. Usually accomplished through movable contacts, ZIF sockets are used by 486, Pentium, Pentium Pro, and other socketed processors (including the latest Pentium 4 and AMD Athlon and Duron models).

ZIP (zigzag inline package)

A DIP package that has all leads on one edge in a zigzag pattern and mounts in a vertical plane.

Zip drive

An external drive manufactured by Iomega that supports 100MB, 250MB or 750MB magnetic media on a 3 1/2" removable drive.

Zip file

A file created using PKZIP, WinZip, or a compatible archiving program.

zipping

The process of creating a PKZIP or WinZip-compatible archive file. See also [unzipping](#).

ZModem

A file-transfer protocol commissioned by Telnet and placed in the public domain. Like YModem, it was designed by Chuck Forsberg and developed as an extension to XModem to overcome the inherent latency when using Send/Ack-based protocols, such as XModem and YModem. It is a streaming, sliding-window protocol.

zoned recording

In hard drives, one way to increase the capacity of a hard drive is to format more sectors on the outer cylinders than on the inner ones. Zoned recording splits the cylinders into groups called zones, with each successive zone having more and more sectors per track, moving out from the inner radius of the disk. All the cylinders in a particular zone have the same number of sectors per track.

zoomed video

A direct video bus connection between the PC-Card adapter and a mobile system's VGA controller, enabling high-speed video displays for videoconferencing applications and MPEG decoders.

Appendix B. Key Vendor Contact Information

Use this vendor quick reference chart to locate primary contact information for vendors mentioned in this book. Be sure to refer to the full vendor database included on the disc accompanying this book. This database contains more detailed contact information and descriptions of services.

Appendix C. Troubleshooting Index

This special index is designed to help you find solutions to problems *fast*. Whether your system is beeping at startup, you're getting the dreaded blue screen of death, or you can't hear your rocket launcher blasts in your latest Unreal Tournament Deathmatch, this index will help you find solutions, quickly and relatively painlessly.

[Pages 1424 - 1440]

Problem		Details About Solution		
Technology	Symptom	Cause	Solution	Page
ATA drive	Can't detect drive with BIOS setup program.	Power cable might be loose or missing.	Reattach power cable.	827
ATA drive	Can't detect drive with BIOS setup program.	Missing or reversed ATA data cable.	Reattach ATA data cable and verify pin 1 to pin 1 at both ends of cable.	821
ATA drive	Can't detect either drive on cable with BIOS setup program.	Both drives might be cabled as master or slave.	Change one drive to master and the other drive to slave.	564, 819
ATA drive	Drive doesn't perform reliably.	IDE cable might be longer than 18".	Switch to 18" cable.	821
ATA drive	Need to install an ATA drive on a system with only Serial ATA connectors.	Serial ATA uses a physically different connector from ATA/IDE.	Use an ATA/IDE drive-to-Serial ATA adapter.	573
ATA drive	Need to install an ATA drive more than 18" from the host adapter.	Ultra-ATA has an 18" limit for reliable performance.	Use a Serial ATA host adapter and drive, or a Serial ATA host adapter and ATA/Serial ATA adapter; Serial ATA cables can be 1 meter long.	569
Audio	Your sound card doesn't sound quite right.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393
Audio	Sound card can't be detected.	Settings already in use by other cards.	Install sound card first.	400

Audio	Can hear music and sounds in Windows but not DOS.	Incorrect settings for Sound Blaster compatibility.	Install emulation settings or run DOS emulation program.	941
Audio	DOS game can't detect sound card correctly.	Inadequate Sound Blaster compliance or missing DOS drivers.	Verify DOS drivers are installed and manually select best emulation.	951
Audio	Game port on sound card conflicts with other game port in system.	Game port uses only a single I/O address range.	Disable sound card's game port or remove other game port from system.	969
Audio	Can't hear any sounds at all.	Various causes, including incorrect connections, mixer setup, power, and so on.	See checklist.	969
Audio	Can hear sound through just one speaker.	Various causes, including incorrect or defective speaker jack/plug, mixer controls, and others.	See checklist.	970
Audio	Volume is low.	Various causes, including mixer controls, volume controls on speakers or sound cards.	See checklist.	971
Audio	Scratchy sound.	Various causes, including interference, ISA sound card, wrong expansion slot.	See checklist.	972
Audio	Computer won't start after installing sound card.	Card might not be installed in slot properly, or Windows IOS might be corrupted.	See checklist.	972
Audio	Speaker or microphone won't work.	Incorrect jacks.	Use correct jack for each device.	976
Audio	Can't use onboard audio.	Audio might be disabled in BIOS.	Enable audio.	451
Audio speakers	Can hear sound through some speakers but not others (4.1 surround and higher audio configurations).	Various causes, including incorrect or defective speaker jack/plug, mixer controls, and others.	See checklist.	971
Audio	Can't use onboard audio.	Audio header cables might be disconnected.	Connect audio header cables to motherboard.	1230

Battery for CMOS/ RTC	System can't maintain correct time when turned off.	Battery is about to fail.	Replace battery.	1216
BIOS	Calendar-related and leap-year bugs.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
BIOS	Can't install Flash BIOS update.	BIOS is write- protected.	Disable write- protection.	434
BIOS	BIOS update fails.	BIOS is corrupted.	Enable Flash Recovery feature and restart update process.	437
CD-ROM, DVD	Can't boot from CD- ROM drive.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
CD-ROM, DVD	Can't boot from CD- ROM drive.	CD-ROM not listed first in Boot order.	Adjust boot device priority.	460
DirecWAY	Download speeds drop drastically after downloading one or two large files.	DirecPC has enabled FAP (Fair Access Policy) slowdowns on your service.	Download less at one time; take breaks between big downloads, or switch to another service.	1068
DSL	Can't use DSL service after self-install.	Service might not be set up by provider; microfilter might not be installed as needed.	Make sure provider has activated DSL service; make sure all conventional phones and telephony equipment has a microfilter.	1063
DSL	Slower-than-expected service.	Line might be poor quality; RWIN or other Windows Registry settings might not be optimized.	Ask installer to test line; adjust Windows Registry with tools available from DSL Reports.	1066
File transfer	Can't connect two computers with standard parallel cable.	Standard parallel is designed for PC-to- device, not PC-to-PC, connections.	Use a LapLink- compatible parallel cable.	1007
Floppy disk	Can't write data to floppy disk; data can be read.	Floppy disk write protection is enabled in BIOS.	Disable floppy disk write protection.	454
Floppy drive	Disk left in floppy drive prevents system bootup.	Floppy drive has higher boot priority than hard drive.	Adjust boot priority in system BIOS.	460

Floppy drive	Contents of all floppy disks viewed appear to be duplicates of the first disk, although the contents of each disk are different.	Changeline support (which detects disk changes) has failed; this problem is also called the "phantom directory."	Verify BIOS setup for drive is correct and that DC jumper (if any) has been set.	685
Floppy drive	Disks placed on top of a TV or monitor have data errors when read.	Magnetic fields generated by the picture tube can corrupt data.	Store disks away from magnetic fields.	688
Floppy drive	Disk access light stays on continuously after system is started.	One end of floppy cable is reversed.	Change reversed end of floppy cable, verifying pin 1 to pin 1.	851
Hard disk	Can't access full capacity of hard drive over 8.4GB.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
Hard disk	Can't access full capacity of hard drive over 8.4GB.	BIOS is out-of-date, and BIOS upgrade is not available.	Install an add-on BIOS card with EDD support.	592
Hard disk	Can't use UDMA drives at full speed.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
Hard disk	Can't use UDMA drives at full speed.	Chipset drivers not installed.	Install drivers provided with motherboard.	1261
Hard disk	IDE drive not ready errors during startup.	Drive not spinning up fast enough at startup.	Enable or increase hard disk predelay time.	452
Hard disk	Can't use drive capacity beyond 528MB.	LBA mode not enabled in BIOS.	Enable LBA mode.	452
Hard drive	UDMA/66 or UDMA/100 drive runs at UDMA/33 on systems that support UDMA/66 or UDMA/100.	Incorrect cable might be in use.	Use 80-wire UDMA cable in place of normal 40-wire IDE cable.	556
Hard drive	Can't read contents of IDE drive over 528MB after moving it to a new system.	Drive geometry or translation not set correctly on new system.	Set correct Cyl-Hd-Sectors setting for drive and LBA or Ext CHS translation.	579
Hard drive	BIOS recognizes full capacity of drive over 8.4GB, but operating system will not.	Some operating systems aren't designed to use drives over 8.4GB.	Upgrade or patch your operating system to achieve compliance.	592

Hard drive	Windows 98 FDISK misidentifies the capacity of a drive over 64GB.	FDISK incorrectly reads the disk capacity.	Download an updated version of FDISK from Microsoft's website.	658
Hard drive	Immediately back up your data and replace your hard disk drive. A failure may be imminent. error message is seen.	The drive uses SMART to predict back up failures, and the SMART system has detected a serious problem with the drive.	Follow the onscreen instructions to back up your drive.	665
Hard drive	Hard drive letters above C: are pushed higher when second drive is installed.	New drive was prepared with a primary partition, which takes precedence over drive letters in the first drive's extended partition.	Prepare additional drives with an extended partition.	832
Hard drive	New hard disk letters conflict with removable media drives not connected to system in Windows 2000/XP.	Windows 2000/XP doesn't change existing removable-media or optical drive letters when drives are present.	Use Disk Management to adjust existing and new drive letters as necessary.	835
Hard drive	Invalid Drive Specification error.	Drive has not been partitioned or high-level formatted, or wrong OS is being used to view drive.	Verify drive is empty with recent Windows versions before running FDISK and FORMAT .	843
Hard drive	Invalid Media Type error.	Drive has not been FDISKed, or drive's format is corrupt.	View drive with FDISK's #4 option, and create new partitions as necessary.	843
IDE drives (see ATA drives)				
Internet	Can't share Internet connection.	Problems with host or client configuration.	See checklist.	1093
IRQ	Conflicts between PCI devices.	PCI IRQ steering not enabled.	Enable PCI IRQ steering.	384
IRQ	Conflicts between PCI devices in Windows 98/Me.	PCI IRQ steering not enabled.	Enable PCI IRQ steering.	384
IRQ	Conflicts between PCI devices.	Devices use slots that share same IRQ.	Move one device to a different slot.	384

IRQ	Conflicts between COM ports.	IRQs shared between COM1 and 3; between COM2 and 4.	Disable unused COM port or change IRQ if possible.	388
ISA cards	ISA cards have hardware conflicts with PCI cards.	Resources not reserved for ISA cards.	Reserve resources for ISA cards.	458
Keyboard	Num Lock stays off when starting system.	Num Lock shut off in BIOS.	Turn on Num Lock in BIOS.	447
Keyboard	Intermittent keyboard failures.	Keyboard cable or keyboard jack might be defective.	Test keyboard cable or jack with digital multimeter.	1029
Keyboard	Keys are sticking.	Keyboard might have spilled drink or trapped debris under keys.	Remove keytops and clean under keys, or wash out keyboard.	1031
Keyboard	USB keyboard works in Windows but not in DOS or BIOS setup.	USB Legacy mode is not enabled in BIOS or not present.	Connect a standard keyboard (or a keyboard/USB adapter) and enable USB Legacy mode.	1027
Keyboard	Standard keys on keyboard work, but not multimedia or Internet keys.	The keyboard driver is not installed or is defective.	Install the latest driver for your keyboard.	1029
Keyboard	Wireless keyboard doesn't work at some angles relative to the computer.	IR sensors in keyboard and on computer are losing line-of-sight.	Reposition IR sensor connected to computer to maintain line-of-sight.	1048
Keyboard	Wireless keyboard doesn't work at long distances (such as with a Media Center PC and big-screen display).	Conventional wireless devices have a 6-foot range.	Use Bluetooth-enabled keyboard to have a range of up to 30 feet.	1048
Keyboard	Wireless keyboard stops working after you moved the computer.	The receiver might be disconnected from the USB or keyboard port.	Reconnect the receiver and re-synchronize the keyboard and receiver.	1052
LAN	Can't use onboard LAN.	LAN might be disabled in BIOS.	Enable LAN device.	451
Modem	Internal modem locks up system when trying to make a connection.	Modem might be set to same IRQ as the serial port the mouse is attached to.	Disable the unused COM port on the system, and set the modem to use that COM port number.	1001

Modem	Modem works correctly with Internet access, but computer-to-computer terminal emulation produces garbage screens.	Incorrect bps, word length, stop bit, or terminal emulation settings compared to remote system's requirements.	Determine correct values for remote system and set up HyperTerminal or other connection program accordingly.	1076
Modem	56Kbps modem connects at 33.6Kbps or less.	Some telephone lines can't provide greater than 33.6Kbps service.	Switch to a broadband service, or use modem bonding to achieve higher speeds.	1082
Modem	Modem drops calls unexpectedly.	You might have call-waiting enabled, which interrupts the modem carrier signal.	Disable call-waiting (ask phone company for details), or upgrade to modems with call-waiting support.	1088
Modem	Can't dial with analog (dialup) modem.	Various causes.	See checklist.	1094
Modem	System locks up after installing internal modem.	IRQ conflicts with other ports or devices.	Use Windows Device Manager to find conflicts and resolve them.	393
Modem	Computer can't detect external modem.	Wrong cable, port problems, or power problems.	Check cable, port setup, and power.	1095
Motherboard	Damage to motherboard from heatsink clips on socketed processors.	Clips slip and scratch motherboard surface.	Attach plastic tape on motherboard before installing heatsink.	1271
Mouse	Mouse doesn't work.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393
Mouse	Can't use PS/2 mouse.	PS/2 mouse port might be disabled.	Enable PS/2 mouse port.	462
Mouse	Mouse doesn't work when attached via adapter to a different port type.	Mouse might not be hybrid type (designed for various ports).	Use adapters only with hybrid mice; use adapter packaged with mouse.	1039
Mouse	Mouse pointer jerks onscreen.	Mouse ball or rollers are dirty.	Clean mouse mechanism.	1040
Mouse	Mouse works for basic operations, but extra buttons or scroll doesn't work.	Incorrect or outdated mouse driver is being used.	Download and install correct mouse driver from vendor site.	1033

Mouse	Mouse works in Windows, but not when booted to DOS.	DOS driver must be loaded from AUTOEXEC.BAT or CONFIG.SYS .	Install DOS mouse driver, and reference it in startup file(s).	1042
Mouse	Wireless mouse doesn't work at some angles relative to the computer.	IR sensors in mouse and on computer are losing line-of-sight.	Reposition IR sensor connected to the computer to maintain line-of-sight.	1048
Mouse	Wireless mouse doesn't work at long distances (such as with a Media Center PC and big-screen display).	Conventional wireless devices have a range of 6 feet.	Use Bluetooth-enabled mouse to have a range of up to 30 feet.	1048
Mouse	Wireless mouse stops working after you move the computer.	The receiver might be disconnected from the USB or mouse port.	Reconnect the receiver and resynchronize the mouse and receiver.	1051
Network	System locks up after installing network card.	IRQ conflicts with other ports or devices.	Use Windows Device Manager to find conflicts and resolve them.	393
Network	Network adapter doesn't work.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393
Network	Can't connect to other computers on network after installing a new custom-built cable.	Cable might not match prevailing wiring standard on network.	Check wiring of other cables to see which wiring standard is used; build new cable to match.	1115
Network	Distant computer works with 10BASE-T network but not with Fast Ethernet.	Computer might be too far from hub or switch because Fast Ethernet has shorter maximum distance.	Install repeater, or use new switch/hub as repeater.	1118
Network	Can't connect to other users on network, although card diagnostics check out.	Might not have correct network software components installed.	See checklist.	1138
Network	Duplicate computer ID error with Windows 9x/Me.	More than one computer has the same name or IP address on the network.	Adjust computer name or IP address with the Network properties sheet.	1141

Network	Users can't see all the computers on the network with Windows 9x/Me.	Multiple workgroup names are in use.	Adjust workgroup name (must match for all on network) with Network properties.	1141
Network	Duplicate computer ID error with Windows 2000 or Windows XP.	More than one computer has the same name or IP address on the network.	Adjust computer name with the System properties sheet; configure IP address with Network Connections.	1141
Network	Users can't see all the computers on the network with Windows2000/XP.	Multiple workgroup names are in use.	Adjust workgroup name (must match for all on network) with System properties.	1141
Network	Users can't share printers or folders with others.	File/Print sharing might not be installed; folders or printers might not be set to shared.	Install File/Print sharing, and then set shared folders and printers.	1141
Network	Network changes made, but don't work.	Most Windows systems must be rebooted to put network changes into effect.	Reboot system and then try network operations.	1141
Network	One user can't access network, but others can.	User might not have logged on to network.	Log off system and log on; provide name and password when prompted.	1141
Network	One user can't access network, but others can.	Loose cables at computer, hub, switch, or wiring closet.	Check all cable connections.	1141
Network	One user can't access network, but others can.	Password cache might be corrupt or have outdated passwords.	Log on to resources again and give new password when prompted.	1141
Network	Can't access Internet or other TCP/IP-based resources.	Wrong TCP/IP settings.	Open Network properties sheet and adjust TCP/IP settings as needed for your network.	1142
Network	IP Address Conflict error.	Duplicate IP addresses on two or more machines.	Open Network properties sheet and enter correct, unique IP addresses for each system.	1142

Network	IP Address Conflict error.	Duplicate IP addresses on two or more machines.	Open Network properties sheet and enable DHCP to permit automatic IP addressing.	1142
Network	Need to create a NetBEUI network using Windows XP.	Can't select NetBEUI as an option.	Install NetBEUI manually from the Windows XP CD-ROM.	1138
Optical drives	Drive slows down when reading CD with a small paper label attached to the label side.	Drive can't run at full speed due to uneven weight distribution and must slow down.	Use full-size labels that cover the entire CD's top surface, or use a marker instead of small labels.	772
Optical drives	CD-ROM drive can't read multiple-session disc.	Drive is not compatible with Orange Book multisession standard (XA standard).	Replace drive with new CD-ROM, CD-RW, or DVD drive.	791
Optical drives	Can't read CD-R or CD-RW disc on a CD-ROM drive, but only on a CD-R/CD-RW drive.	CD probably was created with packet-writing software and not closed before being removed.	Return CD-R or CD-RW disc to original system and close session.	757
Optical drives	CD-ROM disc can be read by 32-bit Windows but not by DOS.	CD was created using the UDF (packet-writing) standard.	Use standard mastering software instead of packet-writing to create CDs for use with DOS.	764
Optical drives	Drive runs very slowly or has read errors.	CD lens might be dirty or dusty.	Use a CD lens cleaner, or install a drive with a self-cleaning lens.	783, 811
Optical drives	Can't read CD-RW media on an older drive.	Drives that aren't MultiRead compliant can't read CD-RW media (usually slower than 24x speed).	Replace drive with a MultiRead-compatible CD-ROM or DVD drive or a CD-RW drive.	791
Optical drives	Can't read CD-RW media on MultiRead CD-ROM drive.	Compatible UDF reader might not be installed.	Install UDF reader from CD-RW disc or by downloading reader from software vendor.	811
Optical drives	Can't write to a 10x or faster CD-RW disc in a 4x CD-RW drive.	10x and faster media meets the High-Speed or Ultra-Speed ReWritable standard; not supported by 2x and 4x CD-RW drives.	Use 2x or 4x media for interchange between 10x or faster and 2x/4x CD-RW drives.	789

Optical drives	Can't write to CD-RW or DVD-RW 1x media.	Media might not be formatted.	Format media with UDF packet-writing software before use.	811
Optical drives	Can't write to CD-RW or DVD-RW 1x media.	Media formatted with different UDF program.	Use same UDF packet-writing software to format media and write to media.	811
Optical drives	Can't write to CD-RW or DVD-RW 1x media.	Media might not be correctly identified.	Eject and reinsert media to force redetection.	812
Optical drives	Can't write to CD-RW or DVD-RW 1x media.	UDF packet-writing software might not support drive.	Contact software vendor for an update.	812
Optical drives	Can't write to CD-RW or DVD-RW 1x media.	Disc might have been formatted with Windows XP's own CD-writing software.	Erase media with Windows XP's CD-writing software and reformat with preferred UDF solution.	812
Optical drives	Can't write to CD-RW or DVD-RW 1x media.	Drive firmware might be out-of-date.	Update firmware.	813
Optical drives	Can't read CD-RW media in a CD-ROM drive.	Media might be damaged.	Reinsert media in original drive; repair media if necessary with UDF packet-writing software utilities.	813
Optical drives	CD-RW or rewriteable DVD drive writes to some types of media more slowly than others.	Drive firmware might not be fully compatible with media type in use.	Download and install the latest firmware for the drive.	813
Optical drives	DVD-RW drive is not compatible with 4x DVD-RW media.	Drive firmware was designed before 4x media was introduced.	Download and install the latest firmware for drive and use only 2x media until update is installed.	813
Optical drives	Cannot install new drive firmware.	Drive is being controlled by other software.	Disable CD-writing software before performing firmware update.	815
Optical drives	Can't read CD-RW media in a DVD.	Drives that aren't MultiRead2 compliant can't read CD-RW or DVD-RAM media.	Replace drive with a MultiRead2 drive.	791

Optical drives	Can't burn a CD-R disc while performing other tasks.	Multitasking operations are causing buffer underruns.	Run only CD-mastering software, slow down burn speed, or upgrade to a drive with buffer underrun protection.	793
Optical drives	Can boot from bootable CD, but can't read contents of CD.	Bootable CD must have CD-ROM driver files and CONFIG.SYS and AUTOEXEC.BAT references to them.	Make sure bootable disk used for creating bootable CD can access CD-ROM.	813
Optical drives	Can't read CD or CD-R discs in a CD-ROM or DVD drive.	Media might not be compatible.	Try different-colored media.	811
Optical drives	Can't read CD-R discs in a CD-ROM or DVD drive.	Media might be written with packet-with packet-x software such as DirectCD.	Reinsert media into original drive, eject media, and select Close to Read on Any Drive.	811
Optical drives	Can't read DVD-RW disc in DVD-ROM drive or DVD player.	DVD-RW media might not be finalized.	Reinsert media into original drive and finalize it before ejecting it.	811
Optical drives	Can't read DVD+RW disc in DVD-ROM drive or DVD player.	DVD+RW media might need to be set to compatibility mode.	Reinsert media into original drive and reset media to compatibility mode.	806
Optical drives	Can't read rewriteable DVD disc in DVD-ROM drive or DVD player.	Disc contains less than 521MB of data.	Add more data to disc beyond 521MB.	811
Optical drives	Can't create writeable DVD.	Incorrect media.	Use +R media in DVD +RW drives; use -R media in DVD-RW drives; either type works in dual-mode drives.	812
Optical drives	Can't create writeable DVD.	Wrong type of project selected in CD/DVD mastering software.	Select DVD project in mastering software.	812
Optical drives	Can't create writeable DVD.	Wrong drive selected.	Select correct drive.	812
Optical drives	Can't create writeable DVD.	Media might be bad.	Try different media.	812
Optical drives	Can't create writeable DVD.	Software might not support recorder.	Get a software update.	812

Optical drives	ATAPI drive runs very slowly, but no read errors.	Wrong cache size.	Adjust cache size in Performance tab of System Properties.	812
Optical drives	ATAPI drive runs very slowly, but no read errors.	CD-ROM drive on same cable as ATA hard drive.	Move CD-ROM drive to secondary ATA cable.	812
Optical drives	ATAPI drive runs very slowly, but no read errors.	UDMA or busmastering drivers might not be installed or enabled.	Install and enable latest UDMA or busmastering drivers.	812
Optical drives	ATAPI drive runs very slowly, but no read errors.	Drive might be using MS-DOS Compatibility Mode (BIOS-based) access.	Reinstall drive to use 32-bit Windows drivers.	812
Optical drives	Can't boot from bootable CD.	System might not support bootable CD.	Verify CD-ROM listed as bootable device and listed first in boot.	813
Optical drives	Can't boot from bootable CD.	Wrong disc format (Joliet or other).	Must use ISO 9660 CD format.	813
Optical	Can't hear music through sound card speakers.	Analog or digital audio cables aren't connected between drive and audio jacks on sound card or motherboard with integrated sound.	Reattach cables to drive and sound card or motherboard; check mixer settings.	942
Parallel port	Can't use onboard parallel port.	Port might be disabled in BIOS.	Enable port.	451
Parallel port	Conflict between onboard parallel port and other device.	IRQ or I/O port address conflicts with other device.	Adjust IRQ or I/O port address in use, or disable port.	451
Parallel port	Can't use ECP mode.	DMA channel conflicts with another device.	Use alternate DMA channel, or use EPP mode instead.	451
Password	Can't access setup or start system because system prompts for password.	Setup and/or power-on passwords are enabled in BIOS.	Clear password settings.	445
Password	Can't access setup or start system because system prompts for password.	Setup and/or power-on passwords are enabled in BIOS.	Clear password settings.	458

Password	Can't access setup or start system because system prompts for password.	Setup and/or power-on passwords are enabled in BIOS.	Clear CMOS if password settings can't be cleared separately.	458
PCI	IRQ conflicts between PCI cards.	IRQs might be shared between slots.	Move conflicting cards to another PCI slot.	447
PCI	IRQ conflicts between PCI cards.	Auto PCI IRQ Priority might not work for all cards.	Set PCI IRQ priority manually.	447
PnP	Can't install new PnP cards.	PnP/PCI configuration data might be corrupted.	Clear PnP/PCI configuration data and restart system.	447
PnP	Problems with PnP cards and configuration.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
Power management	System can't use power management features.	Power management disabled.	Enable power management.	459
Power management	Can't control power management through Windows.	ACPI power management disabled.	Enable ACPI power management.	459
Power management	Can't use ACPI power management.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
Power management	System locks up or hardware malfunctions when power management is used.	Some older peripherals are not compatible with power management.	Disable APM power management in the system BIOS; disable ACPI power management with Windows' Power properties sheet.	1202
Power supply	System reboots (cold boots with memory check) spontaneously.	Power Good voltage level out of limits.	Check power supply with DMM; replace power supply if defective.	1206
Power supply	Dell power supply fails and replacement has different-colored wires for connectors.	Dell changed to a non-standard version of ATX for systems built September 1998-2000; standard power supplies will not work and will fry!	Buy a Dell-brand or Dell-compatible power supply, or replace motherboard and power supply with standard models.	1182
Power supply	System won't start; power is going to system.	Voltage slider on power supply might be set to wrong voltage.	Set power supply to correct voltage level for local current.	1190

Power supply	Power supply fails after additional components are added to system.	New components require more 5V power than old power supply can provide.	Replace failed unit with a 300-watt or larger unit.	1196
Power supply	Hard disk or fan won't turn.	Defective or overloaded power supply.	Replace failed unit with a 300-watt or larger unit.	1202
Power supply	Electrical shocks on case.	Defective or overloaded power supply.	Replace failed unit with a 300-watt or larger unit.	1202
Power protection	Surge suppressor indicates ground fault.	Outlet lacks ground, or it might use a three-prong-to-two-prong adapter.	Use outlet tester to verify proper wiring in outlets used for computers.	1323
Printer	Parallel printer prints very slowly.	Printer might be attached to non-IEEE or non-ECP parallel port.	Set port to use mode recommended for printer and switch to IEEE-1284 cable if necessary.	1003
Printer	Your printer prints gibberish.	Hardware resource conflict if correct driver used.	Use Windows Device Manager to find conflicts and resolve them.	393
Processor	Can't overclock multiplier.	Multiplier locked on recent AMD, Intel CPUs.	Adjust bus speed instead.	462
Processor	Can't use FC-PGA processor in PGA-370 socket.	Change in voltages and pinout.	Upgrade motherboard or use third-party PGA/FC-PGA adapter.	93
Processor	Can't use PGA or FC-PGA processor in Slot 1.	Wrong form factor.	Use slot-key adapter.	93
Processor	Poor heat transfer from processor to heatsink.	Gaps between processor and heatsink faceplate.	Attach thermal interface pad or grease to processor before attaching heatsink.	1271
Processor	Pentium miscalculates floating-point math.	Errata 23 in Pentium processor.	Have Intel replace affected processor, or use updated processor.	130
Processor	Improper CPU identification during POST.	Old BIOS.	Update BIOS from manufacturer.	213

Processor	Improper CPU identification during POST.	Board is not configured properly.	Check manual, and set board accordingly with proper bus and multiplier settings.	213
Processor	Can't install newer processors.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
Processor	System won't start after new processor is installed.	Processor not properly installed.	Reseat or remove and reinstall processor and heatsink.	213
Processor	System won't start after new processor is installed.	BIOS doesn't support new processor.	Update BIOS from system or motherboard manufacturer.	213
Processor	System won't start after new processor is installed.	Motherboard can't use a new processor.	Verify motherboard support.	213
Processor	System doesn't recognize Athlon 64 X2 as a dual-core processor.	A BIOS upgrade is necessary for dual-core support on some systems.	Update system BIOS with a BIOS version that's dual-core compatible.	429
RAID	ATA or SATA drives cannot be configured as a RAID array.	RAID function in BIOS might be disabled.	Enable RAID function.	451
RAM	RAM test not detecting any problems and is finishing too quickly.	L1 and L2 memory caches might be enabled.	Disable memory caches before testing memory.	462
RAM	Soft (random) errors occur after adjusting memory timing in BIOS setup.	Refresh rate set incorrectly in BIOS.	Autoconfigure memory timing in BIOS.	448
RAM	Can't determine exact location of bad memory.	Bad memory could be located in any module installed.	Isolate memory defect to find bad module and replace it.	530
RAM	Can't insert 168-pin DIMM into the motherboard.	DIMM might be wrong voltage or type for motherboard.	PCs use unbuffered 3.3V DIMMs; others will not fit.	501
RAM	RIMM-based system won't boot up with some RIMM sockets empty.	All RIMM sockets must have memory or continuity module installed.	Install continuity modules into a RIMM socket without memory.	507
RAM	Can't determine speed or type of memory module.	Some memory modules aren't labeled.	Look up memory chip characteristics to determine module speed and type.	509

RAM	Single 72-pin SIMM not recognized on P5-class system.	Memory must be added in banks of 64 bits on P5-class systems; 72-pin SIMM has 32 bits.	Add pair of identical SIMMs as supported by motherboard.	512
RAM	System won't boot after installing new memory.	Memory might be too slow for system.	Install new memory as fast or faster than previous memory.	513
RAM	System locks up; mixed metals (gold/tin) used in sockets and modules.	Corroded memory sockets result from mixing tin sockets/gold memory or vice versa.	Remove memory, clean sockets, and use memory with same metal as sockets.	498
RAM	Soft (random) memory errors.	Power glitches or noise on the line.	Replace power supply if it tests out-of-spec, or install power conditioning equipment.	514
RAM	Soft (random) memory errors.	Incorrect type or speed.	Use memory that matches recommended type and meets or exceeds recommended speed.	514
RAM	Soft (random) memory errors.	RF (Radio Frequency) interference.	Move causes of RF away from system.	514
RAM	Soft (random) memory errors.	ESD (electrostatic discharge).	Use antistatic spray on screen and keyboard and install antistatic mats near system.	522
RAM	Memory parity interrupt error message.	Parity checking has detected an error in RAM.	Shut down the system and restart it; remove and reinstall memory.	516
RAM	Out of memory error after upgrading system with AGP card beyond 512MB of RAM.	Windows 9x/Me can't handle memory addresses beyond 512MB along with AGP aperture addresses.	Use no more than 512MB of RAM with Windows 9x/Me and AGP video.	899
Removable-media drive	Can't boot from SuperDisk LS-120 drive.	BIOS is out-of-date.	Upgrade Flash BIOS.	429

Removable-media drive	Can't boot from LS-120 SuperDisk or Zip drive.	ARMD-FDD (ATAPI Removable DeviceFloppy), Zip, or LS-120 drive listed after hard drive in boot order.	Adjust boot priority in system BIOS.	460
Removable-media drive	Zip 750 reads and writes to Zip 250 media very slowly.	Drive must adjust read/write speed to use older media.	Use Zip 750 media for full-speed performance.	691
Removable-media drive	Zip 250 reads and writes to Zip 100 media very slowly.	Drive must adjust read/write speed to use older media.	Use Zip 250 media for full-speed performance.	691
Serial ATA drive	System has no Serial ATA ports.	Most systems need a Serial ATA card to enable Serial ATA support.	Install a Serial ATA card into a PCI slot.	825
Serial ATA	Drives are not recognized by system.	Some systems have disabled Serial ATA ports.	Enable onboard Serial ATA ports.	451
Serial port	Can't use onboard serial port.	Port might be disabled in BIOS.	Enable port.	451
Serial port	Conflict between onboard serial port and other device.	IRQ or I/O port address conflicts with other device.	Adjust IRQ or I/O port address in use, or disable port.	451
Serial port	COM3 and above work in Windows, but not DOS.	DOS can use only COM1 and COM2 due to BIOS limitations.	Use only COM1 or COM2 for DOS applications.	999
Startup	System won't start; no error messages onscreen.	Various fatal errors.	Install POST card; restart system to determine error codes and diagnose problem.	466
Startup	System won't start; various error messages indicating system can't boot.	Hard disk might not be connected to system, partitioned, formatted, or set up correctly in BIOS.	Check drive cabling, drive partitions, and BIOS configuration.	467
Startup	Problems during POST.	Various causes.	Use checklist.	1347
Startup	System beeps several times several times on; doesn't start properly.	Serious or fatal hardware errors.	Count beeps and pattern; determine BIOS used and look up beep code to determine problem.	1293

Startup	System displays error message when turned on; doesn't start properly.	Serious hardware error.	Look up error code in Technical Reference on CD.	1293
Startup	System doesn't start properly; might not beep or display error codes.	Serious or fatal hardware errors.	Install POST diagnostics card and restart system; look up I/O port POST checkpoint code.	1293
Startup	Newly-assembled system won't start.	Various problems.	See checklist.	1257
Startup	System can't boot from hard drive.	Configuration problem with system or drive.	See checklist.	1305
Startup	Missing Operating System error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	1354
Startup	NO ROM BASIC - SYSTEM HALTED error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	468
Startup	No boot device available strike F1 to retry boot, F2 for setup utility error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	468
Startup	Invalid drive specification error.	No partition on disk.	Use FDISK, Disk Management, or equivalent to partition drive.	843
Startup	Invalid Media Type error.	No valid format on drive.	Use FORMAT or Norton Disk Doctor.	843
System	Problems with adapter cards.	Various causes.	See checklist.	1348
System	System unstable when overclocking.	Incorrect voltage to processor.	Use motherboard that allows fine adjustments to processor voltage.	56
System	System is dead, no beeps, no cursor, no fan.	Power cord failure.	Plug in or replace power cord.	213
System	System is dead, no beeps, no cursor, no fan.	Power supply failure.	Replace power supply with known-good one.	213

System	System is dead, no beeps, no cursor, no fan.	Motherboard failure.	Replace motherboard with known-good one.	213
System	System is dead, no beeps, no cursor, no fan.	Memory failure.	Remove all memory except bank 1 and retest; swap bank 1 if no boot.	213
System	System is dead, no beeps, or locks up before POST begins.	All components either not installed or incorrectly installed.	Check all peripherals, especially memory and graphics adapter. Reseat all boards and socketed components.	213
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Improperly seated or failing graphics adapter.	Reseat or replace graphics adapter. Use known-good spare for testing.	213
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Poor heat dissipation.	Check CPU heatsink/fan; replace if necessary; use one with higher capacity.	213
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Improper voltage settings.	Set motherboard for proper core processor voltage.	213
System	System powers up, fan is running, but no beep or cursor.	Processor not properly installed.	Reseat or remove and reinstall processor and heatsink.	213
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during POST.	Wrong motherboard bus speed.	Set motherboard for proper speed.	213
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Wrong CPU clock multiplier.	Set motherboard for proper clock multiplier.	213
System	Device transfers data inaccurately.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393

System	System frequently locks up.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393
System	System locks up after running for a time.	Overheating.	Check case and processor fans.	1327
System	System locks up when office equipment such as copiers or microwave ovens nearby are operated.	Corrupted power.	Plug computer into a separate circuit from such devices.	1341
System	POST reports system errors.	Various problems.	See checklist.	1347
System	Some software doesn't run correctly.	Various problems.	See checklist.	1348
System	Hardware and software bugs.	BIOS is out-of-date.	Upgrade Flash BIOS.	429
System	Memory address conflict between devices.	Two devices are using the same upper memory block.	Move one device to a nonconflicting UMB address.	545
System	Intermittent lockups, memory and drive glitches.	Improperly wired outlets might be providing bad power.	Use an outlet tester to check ground and polarity.	1323
System	Intermittent lockups, memory and drive glitches.	Other devices on circuit could be causing problems, such as AC units, coffee makers, and so on.	Move computers to their own circuit.	1341
System	Problems after system startup with hardware.	Various causes.	Use checklist.	1347
Tape drives	Can't run tape backup or restore; bad block errors during restore.	Defective tape cartridge, dirty heads, defective cabling, or incorrect software settings.	Replace cartridge, clean heads, check cabling, and rerun confidence test with blank cartridge.	719
USB	Can't use USB ports on system.	USB ports might be disabled, or your system has the wrong Windows version.	Enable USB ports in BIOS, and verify you are using Windows 98, Me, 2000, or XP.	986
USB	USB ports available in BIOS but not visible on system.	USB header cables not installed on motherboard.	Install USB header cables.	986

USB	USB game controller doesn't work with some older games.	USB game controller might not perfectly emulate gameport-based controllers.	Check with software vendor for patches or workarounds.	1048
USB	Can't use USB keyboard and mouse outside of Windows.	USB Legacy support is disabled in BIOS.	Enable USB Legacy support.	456
USB	Can't use USB devices.	USB is disabled or not assigned an IRQ.	Enable USB; assign IRQ to USB.	456
USB	Bus-powered peripherals aren't recognized unless they are removed and reattached.	Power supply might be failing.	Test power supply and replace if voltage levels don't meet specifications.	1202
USB	USB 2.0 ports aren't supporting USB 2.0 devices at top speed.	USB 2.0 ports might not be configured correctly.	Enable USB 2.0 support in system BIOS and install correct drivers.	987
USB	USB keychain drive is not recognized by Windows 98 but is recognized by later versions.	Windows 98 does not have built-in support for USB keychain drives.	Install the correct driver on the Windows 98 system.	697
USB	USB peripherals work when plugged into the computer but not when plugged into a hub.	External hubs that are bus-powered might not provide enough power for some devices.	Use the Power dialog box on the USB hub properties sheet in Device Manager to see the power requirements for a device and the power available.	981
Video	Onscreen icons too small at high resolutions.	High resolutions use more dots onscreen, so each dot takes less screen area and fixed-size icons are smaller.	If you use Windows 98, 2000, or XP, enable Large Icons.	868
Video	Garbage appears on your video screen.	Video, DirectX, or mouse driver problems.	Adjust Hardware Acceleration slider.	901
Video	Can't use AGP card as primary video.	PCI video is set as primary video.	Switch primary video to AGP card.	445
Video	Color depth drops below desired setting when resolution is increased.	Video card doesn't have enough RAM to display the resolution at the same color depth.	Upgrade to a video card with more RAM, or decide whether high resolution or higher color depth is more important.	895

Video	CRT display is steady at lower resolutions but flickers at higher resolutions.	Higher refresh rates are needed at higher resolutions to avoid flicker.	Adjust display adapter properties to higher refresh rate if supported by monitor.	876
Video	Monitor picture is distorted.	Incorrect geometry adjustments; can vary with resolution.	Use digital picture controls to lock in desired picture quality.	879
Video	Windows can't display more than 256 colors.	Windows might have incorrectly identified the video card chipset.	Manually select the correct chipset with the Advanced option on the Display properties' Adapter section.	895
Video	Mouse pointer problems are visible onscreen.	Buggy video or mouse driver.	Upgrade video and mouse driver software; adjust acceleration one notch down.	901
Video	Frequent screen lockups or invalid page fault errors.	Buggy video driver.	Upgrade video driver or adjust acceleration to None.	901
Video	System chooses wrong adapter as primary in a multiple-monitor configuration.	BIOS controls which PCI slot (or AGP) is for primary video.	Adjust BIOS options for primary video, or change slots if both adapters are PCI.	904
Video	Secondary monitor not available on Display Properties Settings tab.	Various causes.	See checklist.	937
Video	Display works in Safe or VGA mode with Windows XP, but is corrupted in other modes.	A Display, DirectX, or mouse driver might be defective.	Update all drivers.	901
Video	3D acceleration isn't working, but normal business applications work okay.	DirectX drivers might be defective.	Update DirectX.	901
Video	Problems with video capture devices.	Various causes.	See checklist.	934
Video	Monitor picture too dull, bright, dark, or out of focus.	Monitor controls need to be adjusted.	Adjust front, side, or rear controls as needed; focus controls might require a long screwdriver.	934

Video	No picture.	Monitor might be in power-saving mode (flashing or yellow LED), have incorrect contrast or brightness settings (green LED), be receiving no picture data; or be disconnected from power.	Activate system; adjust contrast and brightness; check data and power cables.	936
Video	Jittery picture quality (LCD).	Display not correctly adjusted, or cables might be loose.	Use display-adjustment software to correct problem; check cables.	936
Video	Jittery picture quality (CRT).	Might be caused by incorrect refresh rate settings, loose cable, interference, or bad power supply.	Reduce vertical refresh rate; check cables; eliminate sources of interference; tap on monitor (temporary fix only).	936
Video	Picture displayed in DOS, not Windows.	Wrong video driver or overclocked video card.	Start system in Safe mode, verify correct video driver, or use default setup for video card clock speed.	937
Video	Can't replace built-in video card with add-on video card.	Card might be in wrong slot or not compatible with system, or system might require manual disabling or onboard video.	Check manual for correct procedure for disabling built-in video, or try a different slot.	937
Video	NVIDIA SLI mode isn't working.	Various causes: MIO bridge not installed; SLI driver disabled; incorrect combination of video cards.	See checklist.	937
Video	ATI CrossFire mode isn't working.	Various causes: DMS-to-DVI cable not connected; incorrect combination of video cards; mode disabled.	See checklist.	937
Windows	Virus warning triggered when trying to upgrade Windows.	Virus warning feature enabled in system BIOS.	Disable virus warning or boot sector write-protect feature.	462

Windows	Operating system will not boot.	Poor heat dissipation.	Check CPU fan; replace if necessary; might need higher-capacity heatsink.	213
Windows	Operating system will not boot.	Improper voltage settings.	Set motherboard for proper core processor voltage.	213
Windows	Operating system will not boot.	Wrong motherboard bus speed.	Set motherboard for proper speed.	213
Windows	Operating system will not boot.	Wrong CPU clock multiplier.	Jumper motherboard for proper clock multiplier.	213
Windows	Operating system will not boot.	Applications will not install or run.	Improper drivers or incompatible hardware; update drivers and check for compatibility issues.	213
Windows	The PC starts in Safe mode (Windows 9x, Windows Me).	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	393
Windows	Problems with operating system or applications.	Various causes.	See checklist.	1348
Wireless input	IR-based wireless mouse or keyboard isn't working.	Direct line-of-sight access to IR receiver might be blocked; batteries might have failed.	Check line-of-sight and move obstacles away from receiver; check and replace batteries as needed.	1052
Wireless input	RF-based wireless mouse or keyboard isn't working.	Batteries might have failed, or interference from other devices might be present.	Check and replace batteries if needed; use different frequencies for nearby RF-based devices.	1052
Wireless network	Wi-Fi 5GHz band device can't connect to other Wi-Fi devices.	Wi-Fi 5GHz is the same as IEEE 802.11a, which is not compatible with other Wi-Fi standards.	Use dual-band devices to connect to all Wi-Fi networks.	1105
Wireless network	Can't connect to network at long distances.	Wireless signals degrade with distance and obstacles.	Add a more powerful antenna to the router or access point.	1106
Wireless network	Can't connect to network at long distances.	Wireless signals degrade with distance and obstacles.	Add a repeater or signal booster to your wireless network.	1106

Wireless network	Some stations can't connect to network.	All stations and router must be set up with same SSID and encryption.	Check SSID, encryption type, and encryption key on router and clients.	1127

A

a-Si (hydrogenated amorphous silicon)

ABC (Atanasoff-Berry Computer)

AC (alternating current)

ACL (access control list)

ACPI (Advanced Configuration and Power Interface)

ACR (advanced communications riser)

ADC (analog-to-digital converter)

ADF (adapter description files)

ADPCM (adaptive differential pulse code modulation)

ADR (advanced digital recording)

ADSL (asymmetric DSL)

AFC (antiferromagnetically coupled)

AGC (automatic gain control)

AGP (Accelerated Graphics Port)

AHA (accelerated hub architecture)

AHRA (Audio Home Recording Act)

AIT (advanced intelligent tape)

ALDC (advanced lossless data compression)

ALi (Acer Laboratories, Inc.)

AMD (Advanced Micro Devices)

AMI (American Megatrends, Inc.)

AMR (anisotropic magneto-resistant)

AMR (audio modem riser)

ANSI (American National Standards Institute)

APA (all points addressable)

API (application programming interface)

APIC (advanced programmable interrupt controller)

APM (Advanced Power Management)

APS (analog protection system)

ARCnet (Attached Resource Computer Network)

ARLL (advanced run length limited)

ARQ (automatic repeat request)

ASCII (American Standard Code for Information Interchange)

ASME (American Society of Mechanical Engineers)

ASPI (Advanced SCSI Programming Interface)

AT (Advanced Technology)

ATA (AT Attachment)

ATAPI (AT Attachment Packet Interface)

ATF (auto tracking following)

ATM (asynchronous transfer mode)

ATX (advanced technology extended)

AVI (audio video interleave)

AWG (American Wire Gauge)

B

BASIC (beginner's all-purpose symbolic instruction code)

BBSs (bulletin board systems)

BBUL (bumpless build-up layer)

BEDO RAM (burst extended data out RAM)

BF (bus frequency)

BGA (ball grid array)

BiCMOS (bipolar complementary metal-oxide semiconductor)

BIOS (basic input/output system)

BLER (block error rate)

BMP (bitmap)

BNC (Bayonet-Neill-Concelman)

BOOTP (bootstrap protocol)

bps (bits per second)

BRI (basic rate interface)

BSOD (blue screen of death)

BSRAMs (Burst Static RAMs)

BTB (branch target buffer)

BTX (Balanced Technology Extended)

BURN-Proof (Buffer Under-RuN error Proof)

C

CAB (cabinet file)

CAI (computer-aided [or assisted] instruction)

CAL (computer-aided learning)

CAM (common access method)

CAM ATA (Common Access Method AT Attachment)

CAP (carrierless amplitude/phase)

CAS (column address strobe)

CAT (category)

CATV (community access television)

CAV (constant angular velocity)

CBI (computer-based instruction)

CBL (computer-based learning)

CBT (computer-based training)

CCITT (Comite Consultatif International Telephonique et Telegraphique)

CCS (common command set)

CD (compact disc)

CD-DA (compact disc digital audio)

CD+G (Compact Disc+Graphics)

CD-I (Compact Disc-Interactive)

CD+MIDI (Compact Disc+Musical Instrument Digital Interface)

CD-MO (compact disc magneto-optical)

CD-R (compact disc-recordable)

CD-ROM (compact disc read-only memory)

CD-ROM XA (compact disc-read-only memory extended architecture)

CD-RW (compact disc-rewritable)

CD-WO (compact disc-write once)

CDMA (code-division multiple access)

CDSL (consumer DSL)

CEB (Compact Electronics Bay)

CERN (Conseil Européen pour la Recherche Nucléaire, or European Organisation for Nuclear Research)

CF (compact flash)

CFCs (chlorofluorocarbons)

CGA (color graphics adapter)

CHAP (Challenge-Handshake Authentication Protocol)

CHS (cylinder head sector)

CIF (common image format)

CIRC (cross-interleave Reed-Solomon code)

CISC (complex instruction set computer)

CLKMUL (clock multiplier)

CLV (constant linear velocity)

CMOS (complementary metal-oxide semiconductor)

CMYK (cyan magenta yellow black)

CNR (Communications and Networking Riser)

COBOL (Common Business-Oriented Language)

COC (chip on ceramic)

CODEC (coder-decoder)

CP/M (Control Program for Microcomputers, originally Control Program/Monitor)

cps (characters per second)

CPU (central processing unit)

CRC (cyclical redundancy checking)

CRT (cathode-ray tube)

CS (cable select)

CS (central switch)

CSA (Canadian Standards Agency)

CSEL (cable select)

CSMA/CD (carrier sense multiple access/collision detect)

CSS (contact start stop)

CSS (content scramble system)

CTFT (color thin film transistor)

D

DAC (digital-to-analog converter)

DAE (digital audio extraction)

DASD (direct access storage device)

DASP (drive action/slave present)

DAT (digital audio tape)

db (decibel)

DBB (dynamic bass boost)

DBR (DOS boot record)

DC (direct current)

DCC (direct cable connection)

DCE (data communications equipment)

DD (double density)

DDE (dynamic data exchange)

DDMA (Distributed DMA)

DDoS (distributed denial of service)

DDR SDRAM (double data rate SDRAM)

DDR2 SDRAM (double data rate 2 SDRAM)

DDS (digital data storage)

DDWG (Digital Display Working Group)

DFP (digital flat panel)

DFT (drive fitness test)

DHCP (Dynamic Host Configuration Protocol)

DHTML (Dynamic Hypertext Markup Language)

DIB (dual independent bus)

DIMM (dual inline memory module)

DIN (Deutsches Institut fu[um]r Normung e.V.)

DIP (dual inline package)

DIVX (Digital Video Express)

DLC (Data Link Control)

DLL (Dynamic Link Library)

DLT (digital linear tape)

DMA (direct memory access)

DMI (Desktop Management Interface)

DMI (Direct Media Interface)

DMM (digital multimeter)

DMT (discrete multitone)

DNS (domain name system or service)

DOCSIS (data over cable service interface specifications)

DoS (denial of service)

DOS (disk operating system)

DPMI (DOS protected mode interface)

DPMS (display power-management signaling)

DRAM (dynamic RAM)

DSK (Dvorak simplified keyboard)

DSL (digital subscriber line)

DSLAM (DSL access multiplier)

DSM (digital storage media)

DSP (digital signal processor)

DSTN (Double-layer SuperTwist Nematic) LCD

DTE (data terminal [or terminating] equipment)

DVD (digital versatile disc)

DVD-A (DVD-audio)

DVD-R (DVD-recordable)

DVD-R DL (DVD-recordable dual-layer)

DVD-RW (DVD phase change rewritable)

DVI (Digital Video Interactive)

DVI (Digital Video Interface)

E

E2000 (Energy 2000)

EAX (environmental audio extensions)

EBCDIC (Extended Binary Coded Decimal Interchange Code)

ECC (error correcting [or correction] code)

ECP (enhanced capabilities port)

ED (extra-high density)

EDD (enhanced disk drive)

EDO RAM (extended data out RAM)

EEB (entry-level electronics bay)

EEPROM (electronically erasable programmable ROM)

EFM (eight to fourteen modulation) data encoding

EFS (encrypted file system)

EGA (enhanced graphics adapter)

EIA (Electronic Industries Association)

EIDE (Enhanced IDE)

EISA (Extended Industry Standard Architecture)

ELF (extremely low frequency)

EMM (expanded memory manager)

EMI (electromagnetic interference)

EMS (Expanded Memory Specification)

ENIAC (Electrical Numerical Integrator and Calculator)

e-PCI-X (embedded PCI-X)

EPIC (explicitly parallel instruction computing)

EPP (Enhanced Parallel Port)

EPROM (erasable programmable ROM)

ESCD (extended system configuration data)

ESD (electrostatic discharge)

ESDI (Enhanced Small Device Interface)

F

FAP (Fair Access Policy)

FAQ (frequently asked questions)

FAT (file allocation table)

FC-PGA (flip-chip pin grid array)

FCC (Federal Communications Commission)

FDDI (Fiber Distributed Data Interface)

FDIV (floating-point divide)

FIC (flex interconnect cable)

FIFO (first in first out)

FM (frequency modulation)

FORTTRAN (formula translator)

FPM DRAM (Fast Page Mode DRAM)

FPT (forced perfect termination)

FPU (floating point unit)

FSB (front-side bus)

FSK (frequency-shift keying)

FST (flat square tube)

FTP (file transfer protocol)

FUD (fear, uncertainty, and doubt)

FWH (firmware hub)

G

GB (gigabyte)

GHz (gigahertz)

GiB (gigabinary bytes)

GIF (Graphics Interchange Format)

GMCH (graphics memory controller hub)

GMR (giant magnetoresistive)

GPA (graphics performance accelerator)

GPU (graphics processing unit)

GUI (graphical user interface)

H

HAN (home area network)

HD (high-density)

HD-ROM (high-density read-only memory)

HDA (head disk assembly)

HDD (hard disk drive)

HDLC (High-Level Data Link Control)

HDTV (high-definition television)

HER (hard error rate)

HFC (hybrid fiber/coax)

HFS (hierarchical file system)

HID (human interface device)

HLF (high-level formatting)

HMA (high memory area)

HP (Hewlett-Packard)

HPA (host protected area)

HPFS (high performance file system)

HPT (high-pressure tin)

HRTF (head-related transfer function)

HST (High-Speed Technology)

HT (hyper-threading)

HTML (Hypertext Markup Language)

HTTP (Hypertext Transfer Protocol)

HVD (high voltage differential)

Hz (Hertz)

I/O (input/output)

IC (integrated circuit)

ICH (I/O controller hub)

iCOMP (Intel Comparative Microprocessor Performance)

ICS (Internet Connection Sharing)

IDE (Integrated Drive Electronics)

IE (Internet Explorer)

IEC (International Electrotechnical Commission)

IED (ID error detection)

IEEE (Institute of Electrical and Electronic Engineers)

IMA (Interactive Multimedia Association)

IMAPI (image mastering application program interface)

IMB (Inter-Module Bus)

IML (initial microcode load)

INCITS (InterNational Committee on Information Technology Standards)

IOS (input/output supervisor)

IP (Internet Protocol)

IPL (initial program load)

IPS (in-plane switching)

IPv6 (Internet Protocol version 6)

IPX (internetwork packet exchange)

IR (infrared)

IrDA (Infrared Data Association)

IRQ (interrupt request)

ISA (Industry Standard Architecture)

iSCSI (Internet SCSI)

ISDN (Integrated Services Digital Network)

ISO (International Organization for Standardization)

ISP (Internet service provider)

ITU (International Telecommunication Union)

JK

JEDEC (Joint Electron Devices Engineering Council)

JPEG (Joint Photographic Experts Group)

Kb (kilobit) 1,000 bits

KB (kilobyte) 1,000 bytes

KHz (kilohertz)

Kib (kibibit) 1,024 bits

KiB (kibibyte) 1,024 bytes

KVAR (kilovolt-amperes-reactive)

KVM (keyboard, video, mouse)

KW/KVA (working power/apparent power)

L

L1 (Level 1)

L2 (Level 2)

L3 (Level 3)

LAN (local area network)

LAPM (link-access procedure for modems)

LBA (logical block address)

LCC (leadless chip carrier)

LCD (liquid crystal display)

LED (light-emitting diode)

LGA (Land Grid Array)

LIF (Low Insertion Force)

LIM (Lotus Intel Microsoft)

LLF (low-level formatting)

LPT (line printer)

LSI (large-scale integration)

LTO (linear tape-open)

LUN (logical unit number)

LVD (low voltage differential)

LZW (Lempel Ziv Welch)

M

MAC (media access control)

MAU (media access unit or media attachment unit)

Mb (megabit) 1,000,000 bits

MB (megabyte) 1,000,000 bytes

MBR (master boot record)

MC (microcartridge)

MCA (MicroChannel Architecture)

MCGA (multicolor graphics array)

MCH (memory controller hub)

MCI (media control interface)

MCM (multichip module)

MDA (monochrome display adapter)

MEB (Mid-Level Electronics Bay)

MESI (modified exclusive shared invalid)

MFM (modified frequency modulation)

MFT (master file table)

MGA (monochrome graphics adapter)

MHz (megahertz)

Mib (mebibit) 1,048,576 bits

MI/MIC (mode indicate/mode indicate common)

MiB (mebibyte) 1,048,576 bytes

MIC (memory in cassette)

MIDI (Musical Instrument Digital Interface)

MIME (Multipurpose Internet Mail Extensions)

MIPS (million instructions per second)

MMC (MultiMediaCard)

MMDS (multichannel multipoint distribution service)

MMO (mobile module)

MMU (memory management unit)

MMX (multimedia extensions or matrix math extensions)

MNP (Microcom Network Protocol)

MO (magneto-optical) modem (modulator/demodulator)

MOESI (modified owned exclusive shared invalid)

MOS (metal-oxide semiconductor)

MOV (metal-oxide varistor)

MP (megapixel)

MPC (Multimedia Personal Computer)

MPEG (Motion Picture Experts Group)

MPS (Multiprocessor Specification)

MR (Microid Research)

MRH-R (memory repeater hub RDRAM-based)

MRH-S (memory repeater hub SDRAM-based)

MS (Microsoft)

MS-DOS (Microsoft disk operating system)

MSAU (multistation access unit)

MTBF (mean time between failures)

MTH (memory translator hub)

MTTF (mean time to failure)

MTTR (mean time to repair)

MVA (multidomain vertical alignment)

N

NAS (network attached storage)

NDP (numeric data processor)

NEAT (New Enhanced AT)

NetBEUI (NetBIOS Extended User Interface)

NetBIOS (network basic input/output system)

NIC (network interface card)

NiCd (nickel cadmium)

NiFe (nickel ferrite)

NiMH (nickel metal hydride)

NMI (nonmaskable interrupt)

NRTC (National Rural Telecommunications Cooperative)

NRZ (non-return to zero)

NTFS (New Technology File System)

NTSC (National Television System Committee)

NVRAM (nonvolatile RAM)

O

OC (optical carrier)

OCR (optical character recognition)

OD (overdrive)

ODI (Open Data-link Interface)

OEM (original equipment manufacturer)

OLE (object linking and embedding)

OLGA (organic land grid array)

OS (operating system)

OSI (open systems interconnection)

OSO (overscan operation)

OSTA (Optical Storage Technology Association)

OTP (one-time programmable)

OTP (opposite track path)

P

P (petabyte)

P3 (Pentium 3)

P4 (Pentium 4)

P4EE (Pentium 4 Extreme Edition)

p-Si (low-temperature polysilicon)

PAC (PCI/AGP Controller)

PAC (pin array cartridge)

PAL (phase alternating line or programmable array logic)

PARD (periodic and random deviation)

PC-DOS (personal computer disk operating system)

PCA (power calibration area)

PCI (Peripheral Component Interconnect)

PCI-X (Peripheral Component Interconnect Extended)

PCIe (PCI Express)

PCL (Printer Control Language)

PCM (pulse code modulation)

PCMCIA (Personal Computer Memory Card International Association)

PDA (personal digital assistant)

PDF (portable document format)

PFA (predictive failure analysis)

PFC (power factor correction)

PGA (pin grid array)

PH (PCI controller hub)

PI (parity inner)

PICMG (PCI Industrial Computers Manufacturers Group)

PIF (program information file)

PII (Pentium II)

PIIX (PCI ISA IDE Xcelerator)

PIO (programmed input/output)

PLCC (plastic leaded chip carrier)

PLGA (plastic land grid array)

PMA (power memory area)

PnP (Plug and Play)

PO (parity outer)

PoP (point of presence)

POP3 (Post Office Protocol 3)

POS (programmable option select or point-of-sale)

POST (power on self test)

POTS (plain old telephone service)

PPD (parallel presence detect)

PPD file (postscript printer description file)

PPGA (plastic pin grid array)

PPI (Programmable Peripheral Interface)

PPP (Point-to-Point Protocol)

PQFP (plastic quad flat pack)

PRI (primary rate interface)

PRML (Partial-Response Maximum-Likelihood)

PROM (programmable ROM)

PSK (phase-shift keying)

PTP (parallel track path)

Q

QAM (quadrature amplitude modulation)

QDR (quad data rate)

QEGA (quantum extended graphics array)

QFE (quick fix engineering)

QIC (Quarter-Inch Committee)

QoS (quality of service)

R

RAB (RAID Advisory Board)

RAID (redundant array of independent [or inexpensive] disks)

RAM (random access memory)

RAMAC (Random Access Method of Accounting and Control)

RAMDAC (RAM digital-to-analog converter)

RBOC (regional Bell operating company)

RCA (Radio Corporation of America)

RDRAM (Rambus DRAM)

RF (radio frequency)

RFI (radio-frequency interference)

RGB (red green blue)

RIAA (Recording Industry Association of America)

RIMM (Rambus inline memory module)

RISC (reduced instruction set computer)

RLL (run length limited)

RMA (return-merchandise authorization)

RNG (random number generator)

ROM (read-only memory)

ROM BIOS (read-only memory basic input-output system)

RPC (regional playback control)

RPS (redundant power supply)

RRIP (Rock Ridge Interchange Protocol)

RS (recommended standard)

RTC (real-time clock)

RTC/NVRAM (real-time clock/nonvolatile memory)

RTF (Rich Text Format)

S

SACD (super audio compact disc)

SAL (soft adjacent layer)

SAS (serial attached SCSI)

SASI (Shugart Associates System Interface)

SATA (Serial ATA)

SCAT (Single Chip AT)

SCMS (serial copy management system)

SCSI (small computer system interface)

SD (super density or secure digital)

SDLC (synchronous data link control)

SDLT (Super DLT)

SDRAM (synchronous DRAM)

SDSL (symmetrical DSL)

SE (single ended)

SEC (single edge contact)

SEC-DED (single-bit error-correction double-bit error detection)

SECAM (Sequential Couleur Avec Memoire)

SECC (single edge contact cartridge)

SECC2 (single edge contact cartridge 2)

SEP (single edge processor)

SEPP (single edge processor package)

SER (soft error rate)

SGRAM (synchronous graphics RAM)

SIMD (single instruction multiple data)

SIMM (single inline memory module)

SIPP (single inline pin package)

SiS (Silicon Integrated Systems)

SLIP (Serial Line Internet Protocol)

SMART (Self-Monitoring Analysis and Reporting Technology)

SMBIOS (system management BIOS)

SMI (system management interrupt)

SMM (system management mode)

SMPTE (Society of Motion Picture and Television Engineers)

SNR (signal-to-noise ratio)

SODIMM (small outline dual inline memory module)

SOJ (small outline J-lead)

SPD (serial presence detect)

SPDIF (Sony/Philips Digital Interface)

SPGA (staggered pin grid array)

SPI (SCSI Parallel Interface)

SPS (standby power supply)

SPSYNC (spindle synchronization)

SRAM (static RAM)

SSE (Streaming SIMD Extensions)

SSI (Server System Infrastructure)

STP (shielded twisted pair)

SVGA (Super Video Graphics Array)

SWAP (Shared Wireless Access Protocol)

SWEDAC (Swedish Board for Technical Accreditation)

SXGA (Super Extended Graphics Array)

T

TAD (telephone answering device)

TAO (track-at-once)

TAPI (telephone application programming interface)

TCM (Trellis-coded modulation)

TCO (total cost of ownership)

TCP (tape carrier packaging)

TCP/IP (Transmission Control Protocol/Internet Protocol)

TDMA (transparent DMA or time-division multiple access)

TEB (Thin Electronics Bay)

TFT (thin film transistor)

TIFF (tagged image file format)

TIP (Trouble In Paradise)

TLB (translation lookaside buffer)

TPI (tracks per inch)

TSOP (thin small outline package)

TSR (terminate and stay resident)

TTL (transistor-to-transistor logic or through-the-lens)

U

UART (Universal Asynchronous Receiver/Transmitter)

UDF (Universal Disk Format)

UDMA (Ultra-DMA)

UI (user interface)

UL (Underwriters Laboratories)

UMA (unified memory architecture)

UMA (upper memory area)

UMB (upper memory block)

UNIVAC (Universal Automatic Computer)

UPC (universal product code)

UPI (Universal Peripheral Interface)

UpnP (Universal Plug and Play)

UPS (uninterruptible power supply)

URL (uniform resource locator)

USB (universal serial bus)

USN (update sequence number)

UTP (unshielded twisted pair)

UXGA (Ultra Extended Graphics Array)

V

VAFC (VESA Advanced Feature Connector)

VBI (vertical blanking interval)

VBR (volume boot record)

VCPI (virtual control program interface)

VESA (Video Electronics Standards Association)

VESA VIP (Video Interface Port)

VFAT (virtual file allocation table)

VFC (video feature connector)

VGA (Video Graphics Array)

VHS (Video Home System)

VID (voltage identification)

VIS (viewable image size)

VL-Bus (VESA local bus)

VLF (very low frequency)

VLSI (very large scale integration)

VM (virtual machine)

VMC (VESA Media Channel)

VMM (virtual memory manager)

VoIP (voice over IP)

VPN (virtual private network)

VRAM (video random-access memory)

VRM (voltage regulator module)

VRT (voltage reduction technology)

VxD (virtual device driver)

[← PREV](#)[NEXT →](#)

WX

W2K (Windows 2000)

W3C (World Wide Web Consortium)

WAN (wide area network)

WAP (Wireless Application Protocol)

WBR (wireless broadband router)

WEP (wired equivalent privacy)

Wi-Fi (Wireless Fidelity)

WORM (write once read many)

WWW (World Wide Web)

XA (extended architecture)

XGA (Extended Graphics Array)

XML (Extensible Markup Language)

XMM (extended memory manager)

XMS (Extended Memory Specification)

YZ

Y2K (year 2000)

ZBR (zoned-bit recording)

ZIF (zero insertion force)

ZIP (zigzag inline package)

ZV (zoomed video)

Installing the DVD

The DVD accompanying this book is playable on both a standalone DVD player (DVD player attached to your television/home theater system) and a DVD drive installed in or connected to your PC.

Standalone DVD Video Players

To play the videos on this DVD, insert the DVD into your standalone DVD video player and navigate the menus using your DVD player's remote, just as you would do with any DVD.

Note

The DVD is region-free. The extra features using Internet (Web) links are not active links; you must enter the specified URLs into your Web browser directly. Extra features and Windows Media Playerformatted videos are also available on Scott's Web site at www.upgradengandrepairingpcs.com.

PC-Based DVD Drives

To play the DVD video content, do the following:

1.

Insert the DVD into your PC's DVD drive.
2.

Run your previously installed DVD player application and select Play.
3.

Navigate the DVD menus as you would any standard DVD video.

Most DVD drives include a decoder/player application. If you do not currently have a DVD decoder/player installed on your system, you can do one of the following:

- Play the disc in a standard set-top DVD player.
- Use an existing DVD decoder with Windows Media Player 9 or later (visit www.microsoft.com/windows/windowsmedia).
- Purchase a DVD decoder to use with Windows Media Player.
- Purchase a complete decoder/player combination, such as PowerDVD by CyberLink (www.gocyberlink.com), or WinDVD by Intervideo (www.intervideo.com).

Here's how to access the Technical Reference files, previous editions of the book, and any other files on the DVD-ROM:

1.

Insert the DVD into your PC's DVD drive.

2.

Open My Computer.

3.

Right-click the icon for the DVD drive containing the disc.

4.

Select Explore.

5.

Navigate through the folders and files just as if you were viewing files stored on your computer's hard drive.

Note

Many of the documents included in the Extras section of the DVD are in PDF format, which requires Adobe Acrobat to view. Acrobat is freely available at www.adobe.com.

System Requirements for DVD-ROM Video

The minimum system configuration is as follows:

- Intel Celeron/Pentium or AMD Duron/Athlon processor, 400MHz
- Windows 98 Second Edition, Me, 2000, or XP
- 64MB of RAM (Windows 2000 and XP require 128MB of RAM)
- 4MB graphics card, 800x600 resolution, 16-bit color
- Direct Soundcompatible sound card
- 4X DVD-ROM drive (UDMA enabled)
- Direct Showcompliant DVD decoder/player software installed
- Direct X 7.0
- Internet Explorer 5.0

Access to DVD Content Without a DVD Player or DVD Drive

If you do not have a set-top DVD player or DVD drive, you can still access all the files included on the DVD-ROM by visiting [www. upgradi ngandrepai ri ngpcs. com](http://www.upgradi ngandrepai ri ngpcs. com). To access these materials on the Web, follow these steps:

1.

Remove the DVD from the package insert and note the password on the DVD label.

2.

Visit [www. upgradi ngandrepai ri ngpcs. com](http://www.upgradi ngandrepai ri ngpcs. com) and follow the DVD link from the home page.

3.

Enter your password as included on the DVD label.

4.

You can then download any of the files provided there, including Windows Media Player versions of the videos, multiple previous editions in PDF format, a hard drive specification database, a vendor database, and more.
